TO THE MEMORY OF

LOUIS VAN HOUTTE,

Nurseryman, of Ghent, Belgium; Founder of the "Flore des Serres"; skilful cultivator and enthusiastic lover of Plants,

THIS NINTH VOLUME OF "THE GARDEN"

IS RESPECTFULLY DEDICATED.

W. R.

Louise, 428; Prince Consort, 334; in Paris, 196; in pots, 375, 630; in winter and spring, 137; new, 241
 Vicks Lindeni, 630

W.
 Wahlenbergia Kitabelli, 47
 Walks, garden, iron chinkers on, 70; gravel, marking, 190; formation of, 234; sawdust as a founder for, 256
 Wallflower, the Harbinger, 100
 Wallflowers, single, 406; yellow, 459
 Wallisia princeps, 165
 Walls, garden, size of wire for, 301; span-roofed houses in place of, 403; the Japan Pear on, 318
 Wall tree protections, 358
 Walnut, and its varieties, 381; the Persian-shaped, 392; hullless Chinese, 62; preserving, 23, 190
 Warts on Vine leaves, 231
 Wash for fruit trees, a good, 562
 Wasps, 347
 Watercress as a therapeutic, 375; v. American Water-weed, 218

Water Hemlock, poisoning by, 300
 Water-plants in the wild garden, 641
 Waterproof garments, how to, 156
 Water, striking cuttings in, 672, 593
 Water-weed, American, destroying, 165
 Weather, the, and the moon, 216; in the Eastern Counties, 371; and the fruit crops, 404
 Wellingtonia gigantea, 62; in Perthshire, 218; shelter for, 342
 Welwitschia mirabilis, 178
 Westminster Aquarium, 28, 99, 120, 123, 636
 Weymouth Pine in White, 168
 Wheelbarrow, the Shanhai, 70
 Whiskey, new use for, 198
 Whitebait, trees in, 124
 Wigandia latifolia, 448
 Wild gardens and woodland flowers, 457, 491
 Willow, the, on the growth of, 460
 Willows, flowering time of, 131; leaves, dear, 230
 Windflower, Cyclamen-leaved, 499; the Scarlet, 606

Window boxes, Carnations in, 74
 Daisies for, 462; plants, Eranthis, 48; Myrrhyphyllum, as a, 119
 Winter, bedding Calceolarias out of doors in, 43; Begonia insignis for, 35
 Zonal Pelargoniums for, 33; gardens, 123; in greenhouses, 97; flowering, Laurustinus for, 246; Iris, new, 237; landscape, beautifying, 191; Spinach, failure of, 47; stove plants in, 310; the Virginia Cedar in, 200; Gesnera cinnabarinata for, 35
 Wintering Beetroot, 47
 Wires on walls, mode of straining, 113; size of, for garden walls, 301
 Wistaria grown as a bush, &c., 663; the White, 483
 Witloof, 96; v. Barbe de Capucin, 238
 Wood ashes, 23
 Woodwork of glasshouses, preserving, 128
 Woodwardia radicans, 230; cristata, 437
 Wood, a new use for, 192; unripe, e. fertility, 292
 Woodruff, the Sweet, 297; and Ivy, 593

Woods, flowers for the, 263, 289; and coppice, acreage of, in Great Britain, 300; Oregon, 371
 Worms in pots, how to destroy, 272

X.
 Xanthochara sorbifolia, 258, 277; propagation of, 436
 Xiphion Hisirio, 29
 Xylophyla facata, 396

Y.
 Yew, the Dovaston, 341; Irish, with single stems, 371
 Yucca, an edible, 608; baccata, 608; brevifolia, 351; californica, 663; greenhouse, 664

Z.
 Zamia intermedia, 487
 Zinnia Darwinii, 80; new race of, 8
 Zonal Pelargoniums for winter decoration, 33

M. LOUIS VAN HOUTTE.

THE late LOUIS VAN HOUTTE was not only a great Nurseryman and the founder of what was considered the most important establishment of its kind in Europe; he was also an enthusiastic lover of plants for their own sake, and a man who in many ways was a benefactor to his Profession. His establishment has long been regarded as the best of its kind, not only in Belgium but also on the Continent, affording, as it did, employment for about 200 persons, and doing business not only in Europe, but also largely in North and South America, China, and Japan. Some idea of the extent of business done here may be gleaned from the fact that about 500,000 plants of Camellias alone were disposed of every year from this nursery. Remarkable among specialities were Palms, and new seedling Azaleas, fine-foliaged and Gesneraceous plants, among which were some fine hybrids. One of M. VAN HOUTTE'S earliest attempts at hybridising was crowned with success, the result being the brilliant *Gladiolus gandavensis*, together with some very beautiful cross-bred seedling *Alstroemerias*, of the beauty of which the late DEAN HERBERT spoke most enthusiastically at the time; and, as is well known, many lovely varieties of *Azalea mollis* have been originated in his establishment. One of his latest successes in this way was the production of *Bertolonia Van Houttei*, one of the most beautiful of all Melastomads, and an acquisition of which he might well be proud. He energetically followed up the introduction of new plants from the Tropics, and it is interesting to find that one of the most successful of all modern collectors, M. BENEDICTE ROEZL, was brought up in M. VAN HOUTTE'S establishment, which was a good school for young gardeners, being remarkable for its completeness in all departments. Not only were plants raised here and sent to all parts of the world by the thousand, not only were catalogues and descriptions of them prepared, printed, and sent out, but one of the most beautiful and useful of all serial horticultural works was edited and the coloured plates prepared under M. VAN HOUTTE'S personal supervision. This work has reached its twenty-second volume, and contains 2260 plates, about the same number of woodcuts or lithographic etchings, and about 4500 articles and notes on plants and other horticultural subjects. From the original drawing to the last printing from the stone and final touching up by hand, these beautiful plates were finished in the nursery, a long corridor-like building being fitted up with tables, presses, and other apparatus for the use of artists and printers.

He died on the 9th of May, 1876, aged sixty-six years, and at his funeral the expression of regret at his loss was universal. The Count de Kerchove, Burgomaster of Ghent, said:—"Gentlemen—The Royal Agricultural and Botanical Society of Ghent has just rendered its last homage to one of its most illustrious members, one who has contributed more than any other to the brilliancy of its fetes and the greatness of its reputation; it has said its last farewell to that eminent horticulturist, who, thanks to his energy and scientific attainments, has founded one of the best horticultural establishments in the world. In his youth, LOUIS VAN HOUTTE was an ardent lover of plants, and as a botanist, in more mature years, he made them his constant study. He therefore eagerly accepted an offer which was made to him to go to Brazil as a collector. In this capacity

he paid a visit to the vast forests which border the Amazon, and later on to the verdurous solitudes of Eastern Africa. He possessed a constitution which successfully withstood the climatic vicissitudes of the Tropics, where the more important of his botanical treasures were collected. On his return to Belgium he was appointed director of the Botanical Garden at Brussels, where he found himself again among the plants which he loved so well. A botanical garden, however, did not afford him all that he desired; he still longed to dwell among those elegant Palms, those sweet-scented Orchids, and those delicate Ferns with which he had met in his foreign travels, and this at length led to his founding the fine establishment at Ghent with which his name has been so long associated. It is unnecessary to advert to the influence which this nursery has had on the horticultural world. As a man VAN HOUTTE was indefatigable, resolute. Even during his last illness he went to Brussels, in order that he might be an eye-witness of his success at that exhibition. His establishment was ever open to all who took an interest in plants and plant culture, both amateur and professional. No effort seemed too much for him, provided horticulture was benefited by it; and this leads me to direct attention to the beautiful house which he had constructed to shelter the *Victoria Regia* and his fine collection of Pitcher Plants and Orchids which he so much loved. His loss, as far as horticulture is concerned, is not, therefore, confined to Ghent; but that city, of which he was the first magistrate for many years, will miss him in other respects. Notwithstanding the high position which he attained, and the honours conferred on him, VAN HOUTTE remained a kind-hearted and modest man, his chief pride consisting in gaining the affection of those under him. His disposition was at all times generous, and his friendship sincere. In short, while horticulture continues to engage our attention, his name will live."

THE GARDEN.

VOL. IX.

THE COUNTRY PARSON IN HIS GARDEN.*

By REYNOLDS HOLE.

THE Country Parson sometimes refresheth himself, as knowing that Nature will not bear everlasting droopings, that all men shun a perpetual Severity, and that instructions, seasoned with Pleasantness, both enter sooner and root deeper in that ground, which hath been described by the Psalmist as the Ground of the Heart; and so long as he doth remember to put bounds and hoops to his Hilarities, and to

Pick out of Mirth, like stones from out his soil,
Profaneness, filthiness, abusiveness,

he doth verify unto himself, and likewise to his friends and neighbours, that proverb of the wise King, which saith, "A merry Heart doeth good, like a Medicine."

Wherefore the Parson, as knowing that he should be unto his people and companions a Teacher and a Guide, striveth to exercise a brave Abstinence and a thoughtful Discreetness, when he chooseth a Recreation, and enjoyeth his ease; keeping himself aloof from evil company, because sins make all equal, whom they find together; and resisting all such excess in the outlay of his Money or his Time, as may prove a robbery and hurt unto his Flock or unto him; all such excitements, as do afterwards unfit men for their duties, leaving them, as do strong Drinks and Dainties, in drowsiness and stupidity; and all such Amusements as have no better purport than to amuse. "If I forget Jerusalem in my Mirth," he saith, "let my right hand forget her cunning." Even in Laughter will my heart be sorrowful; and the end of that Mirth is Heaviness.

And so, albeit the Country Parson hath delight in horses, esteeming them as noblest of all Beasts, and most admiring them outstretched at Speed, and would gladly go forth with his neighbours to witness their Honest contention, yet keepeth he away from the Course or Race, as one who knoweth that lewd fellows of the baser sort, yea the very Subjects, be there gathered together, not to please themselves with the Beauty, the Grace, the Swiftness of the Steed, nor yet with the Skill and Courage of his Rider, but to outwit and to defraud one the other, and to make a jest of Dishonour and Vice. He seeth how that fair Houses be desolate, and ancient Estates be estranged, by the Gambling and Wagering of reckless men, who might have made those Homes Happy, and bequeathed those broad lands to their Heirs; he readech how that Madness and Suicide have come unto Fools, who have staked all that remained upon a Race, or upon a Throwing of Dice; and in the wail of the widow and in the exceeding bitter cry of the fatherless, robbed of their Heritage, he heareth and heedeth a

Voice, that warneth him and all, "Enter not into the path of the Wicked, and go not into the way of evil men."

And though the Country Parson hath learned to ride, in those days, when, as the Latin Poet writes, unbearded Youth in horse and hound rejoices, and though he hath Knowledge, it may be, from a brave Experience, how to clear the strong Wall of Stone, the Fences of Oxen, and the Brook, running broad and deep; and though he honoureth the Chase as an Exercise Brave and Healthful, teaching men to be cool yet bold in danger, and above all as bringing them together, that there be more Friendship and larger Sympathies; though it delighteth him to see the young Squire coming home, with the Brush at his Saddle-Bow; though he leaves the unfinished sentence glistening on his Sermon, or the Lunch half-eaten on his plate, should his ears catch the sounds, or his eyes the signs, of the Hunt; and though his long Clerikly Coat may be seen flying over the Dike and topping the Stake-and-Bound, with half his parish panting in his wake; yet is the Chase (unless his cure be small, and his means large, and he ride not oft, but Valourously), beyond his reach and precinct. It hath a greater disbursement, both of Gold itself, and of the Hours which are yet more golden, than agreeth with the income of a Minister, or with the duties of a Priest.

Next, and as doth concern the Shooting with a Gun, albeit the Country Parson walketh openly and without Shame, if Conscience hinders him not, amid the Stubbles and Turnips of his Glebe, the Coverts of my lord, the Sedges of the Brook; and though the whirring Partridge, the rocketing Pheasant, the gliding Woodcock, the quacking Mallard, the twisting Snipe, and the nimble Coney, escape not his steady aim;—yet, because of jealousies as concerns the Glebe aforesaid, which, for the most part, too small to furnish sport by itself, interferes with the Preserves of others, and because he liketh not the system now in vogue of slaughtering by hundreds poor homebred birds, so tame that they will hardly rise unto destruction—the Parson goes out but rarely to seek his Recreation with the Gun.

As to Angling with the rod, there be seldom found among Parsons he that takes to this diversion, as good Master Isaac Walton and others, a mighty Affection, one who causeth the Fly to fall so lightly on the stream, and the Minnow to spin so Minnowishly in it, that the williest of Fishes look and die. A good fisherman is rare, as a Judicious Hooker among the Clerks, and indeed for that matter among the Laymen too; and, where may be the Desire and Ability, there lacketh oft the Opportunity. Nor must they, who are commanded to be Fishers of Men, go far or frequently in search of it.

The Country Parson has loved Cricket, man and boy, these thirty years or more, and will never lose that Love. He is the Founder and Friend of the village club, and cannot pass his

* Writ after the manner of George Herbert. Some of the sentences, and several of the phrases, are from the writings of Herbert

Schoolboys, playing on the Green, without bowling a Ball or hitting it. It stirreth his pulse, and maketh his Heart glad, to run up, when he taketh his holiday, unto the Ground at Lord's, and to see the Boys of his School, or the Youths of his University, or the Men of his County, contend for victory. But he thinketh it unseemly to present himself Publickly in the similitude of a Bale of Flannel, and in the costume of one, who Saveth the Stone; and he loseth moreover early in manhood that Agility of Hand and Speed of Foot, without which he may not Excel. None the less, though he hitteth too late to Leg, and misseth the Catch to Point, and breatheth audibly between the Wickets, his heart is with the Grand old Game; and one of the first duties, which he teacheth his sons and the sons of his parishioners is to Play with a Straight Bat.

In Archery, the Country Parson, whose forefathers fought at Agincourt, and who hath firm faith in Robin o' th' Wood, doth take a pleasant pride, and it is unto him a Wholesome and Cheap exercise of the Muscles, and a welcome Restoration of his mind. But unto few of his Order is given such space of level sward as the Pastime needeth, or that leisure for practising the Art, as he must have, who would succeed therein.

Of all Games that, as it seems to me, suiteth him best, which (though it be very ancient, being identical, or, if not identical, resembling closely the *Sphaeristike* of the Greeks) hath but recently been brought to us—to wit, Lawn Tennis. Not so much because it be in name Episcopal, and suggestive to the Parson of the duties, which he oweth to his Ordinary, or of the highest Honours to which his Hope aspires, but because it revives the Racquets of his youth, and without overstraining the locomotive capacities of his Manhood, brings to him, amid cheerful Companions, that glow of Exercise and elevation of Spirit, so refreshing, and so helpful to his bodily Health.

But few Rectors, fewer Vicars, and no Curates, have grounds large enough for a Tennis-Court, or friends at hand to play, if they had.

The Country Parson careth not for Croquet, and though he doth, as a rule, discourage that style of phraseology, which goeth by the name of Slang, and doth condemn all severe and sweeping Denunciations, yet hath he been seen to smile his consent, when his Squire hath pronounced his conviction, that "Croquet was utter Rot."

Seeing, then, that these Diversions do carry with them, so far as we clergy be concerned, both difficulties and Dissuasions, and seeing that at best they are but for the minority, and then only for a Season, we must pursue our inquiry after some other Recreation, which, like the Cup, which cheers but not inebriates, shall Refresh without relaxing the Country Parson.

We shall find it, if I mistake not, in THE GARDEN.

In the Culture of a Garden, as it seemeth to me, the Country Parson hath a Refreshment, pure and pleasant, within his reach always, and within his income also, because Horticulture, if it be discreetly done, tendeth to increase rather than to impair his means of Maintenance; a Refreshment, which, as my lord Bacon saith, is greater than all others else, seeing that it doth renovate Mind and Body alike, without any such Excess or Excitement as doth bring on afterwards a Weariness and Debility. As to other Pastimes, Sports, and Recreations—albeit I do commend them in their temperate uses and their righteous applications—men must go abroad and roam afield in quest of them; and they be given for our Enjoyment at certain Seasons only; and oftentimes they are hindered by unkindly Weather, by Winds, and by Rains, by Droughts, and by Frosts; and their Vexations and Disappointments are not few, as, for example, when he who Hunteth the Fox liketh not a Fence, and goeth a circuit, and seeth the Hounds no more; or when he, who Shooteth Jealously, misseth the Game, and his Rival (as the phrase is) Wipeth his Eye. Whereas I do Affirm, and will humbly endeavour to Attest, that the Country Parson hath in his Garden, not only a Healthful Pursuit and a Happy Pastime, appropriate to his means and to his Vocation, but an Enjoyment, moreover, which, as the Lover said of his Phyllis, "never fails to please." First of all, I would maintain, that there is no Garden so small but that it may constantly supply a Delight and Interest, to those who tend it with Love and care, in the Spring, the Summer, and the Autumn; and that there is no Purse so small, but that,

when there is the wish, Economy may afford the little Greenhouse and the Frame, which prolong, through dull Winter, the Gardener's joy. As a rule, the Parish Priest is poor, and when he remembereth the Birthplace at Bethlehem and the Home at Nazareth, he may well learn from his poverty therewith to be content; but it would be hard, indeed, if he could not purchase unto himself that which hundreds of Artizans, by the fair Town of Nottingham and elsewhere, can buy from their wages—"a Bit o' Glass." Assuredly, I say, there is no Garden so small, but that the fair Flowers of the Season may visit it in their course, from the Christmas to the Autumnal Rose; and there is no Greenhouse so small, but that Beauty shall glow therein, if only Affection Watch. "Allers summ't to cheer one up, summ't bright for th' eye, and m'ppen sweet for the nose, indoors or out, summer and winter," said a Mechanic; and surely the Country Parson in the purer air, far away from the smoke of the Town, and having his Plot of ground and his Glass at his door, may achieve a like success, and make his Garden a Joy for ever.

What Treasures he may collect, though his Space be small, what Gems, varied and lustrous, though he doth hold, as it were, the Casket in his hand—yea, Pearls more Blue than the Turquoise, more Purple than the Amythest, more Green than the Emerald, more Golden than the Topaz, more Crimson than the Carbuncle, and Whiter than Pearls—he who maketh for himself as, now, Happily for themselves, so many make a Rock, or Alpine, Garden. Just a few large Stones—and I would have him who placeth them betake himself first where he may best observe how Nature maketh her gardens amid the Rocks—and intermixed soils, Dry and Damp, Sand, Loam, and Peat, some for the Sunshine and some for Shade, for he shall have plants Diverse and Multiform; and then, if he will study with his Mind and admire with his Heart, Nurse the Weakly, and Nourish the Strong, Exhume the Groundsel, and Inhume the Slug. Oh, for him, what visions of Loveliness! What an Alphabet is here for the young pupil's eye to learn:—Acæna, Alyssum, Anemone, Arabis, Aubrietia; Bellis and Bluebell; Campanula, Cerastium, Cheiranthus, Cyclamen; Daphne, Dianthus; Erica, Erythronium; Fumaria and Funkia; Gentian and Geranium; Helianthemum and Houseleek; Iberis and Iris; Lithospermum and Lychnis; Menziesia and Myosotis; Nertera and Nierembergia; Orobus and Oxalis; Plox and Primula; Ramondia and Ranunculus; Saxifraga and Sedum; Thymus and Trillium; Veronica and Viola; and when he has mastered these, what volumes for him to read. As a book-hawker's pack is to the Bodleian, so are all other Libraries to the illustrated Library of Flora.

Next, be it well considered that a Garden hath for the Parson goodly thoughts and Instructions, for it doth Remind him continually how Blessed was the first Gardener, so long as he kept Innocency and obeyed his Maker, and how Briar and Blight, and all that is evil, are the curse and consequence of Sin, and can only be uprooted with Sweat of Brow. If he be sorrowful when he marketh Decay and Death around him, as he who wrote—

Then went I to a Garden, and did spy
A Gallant Flower,
The Crown Imperial. "Sure," said I,
"Peace at the root must dwell.
But, when I digg'd, I saw a worm devour
What shew'd so well;"

he findeth Comfort and Hope with it when he seeth the Resurrection of the Spring and thinketh of his own; he remembereth Who bade him, "Consider the Lilies;" and he hath Faith that the same Power and Love, which brought so much Beauty from the mean, dry Bulb, can bring Angels out of the dust of the Grave.

When he tieth out a branch or pruneth it unto the Shape which he deemeth the best, he must be oft reminded of the young "trees of the Lord, full of sap," which it is his Duty to train Heavenward; and how that sharp knife with which he cuts away excess, deformity, and disease, is like the Iron of Repentance in the Sinner's Soul.

And not only in his Meditations, but in his Ministrations also, shall his Garden be the Parson's Friend. He rejoiceth fervently to make an offering of his fairest Flowers to Him,

Whose Breath perfumes them
And Whose pencil paints,

upon the Altar, which is to him a Royal Throne—*Solium CHRISTI*, as it was called of old. He taketh them to Brighten the dreary chambers of the sick, and there he maketh them his Text, and persisteth, that though man cometh up and is cut down like a Flower, like a Flower he is not dead but sleepeeth, and shall bloom to an Eternal Summer, upon the New Earth, which will be Heaven also.

A PARADISE OF FLOWERS.

We have already to lament the vulgarisation of so many beautiful places, both here and on the Continent, by hordes of summer tourists, attracted thither either by hygienic repute, or by the enthusiastic descriptions of those who have been fortunate enough to see the land in its primitive loveliness, that it becomes an instinct in those who are not merely content to do this or that tour, and pass on to do some other in like manner, to be discreetly silent and keep their own counsel about new scenes and routes. Were I to become the lucky discoverer of a new station in this island for one of our rapidly disappearing native plants, such as *Cypripedium Calceolus* or *Menziesia corymbosa*, no ordinary bribe would induce me to publish the same in *THE GARDEN* or any other paper; for the result would surely be a flight of hungry botanists, terrible with trowel and tin case, who would swoop down and loot the treasure, as sure as Kales are curly. But it is otherwise when a vast tract rich in flowery wealth, and lying out of the regular tourist route is visited. The resources of an Alpine region are so inexhaustible on account of the inaccessible storehouses of flowers, and the season during which it can be visited is so comparatively short, that the injury done by a whole battalion of botanists, is infinitely less than is caused in this country when prizes are offered (as too often they are) at country flower shows for the best bouquet of rare wild flowers. No one who loves them truly can ever forget his first visit to the home of Alpine flowers. It was my fortune this year to visit with a congenial companion one of the richest valleys in the Ober-Engadine, and although the season was well-nigh spent—it was early in September—many flowers were still recognisable and a few in full blossom. The drive from Coire to Ponté over the Albuja Pass is very fine. It occupies twelve hours, and as the road is very steep, half the time may be spent on foot, walking up the hills in front of the deligence. On the Swiss side of the pass the most conspicuous flower in the forests at that late season, was the Swallow-wort Gentian (*Gentiana asclepiadea*), and the Alpine Toadflax (*Linaria alpina*), with bright purple, scarlet-tipped flowers appeared to grow even brighter than on rock-work at home, where it is not seen as often as it should be. Here and there a stray blossom of *Gentiana ciliata*, *verna*, and *bavarica*, reminded us that June is the month to visit these high regions. Just before reaching Weissenstein, the highest point of the road, 7,000 feet above sea level, we got above the forest, here composed almost entirely of Spruce and Pinus Cembra. A vast treeless waste surrounds the tavern at Weissenstein; we noticed there a dwarf lilac-rayed Aster lighting up the roadside, and sheets of a blue Monk's-hood, probably *Aconitum autumnale*, were very gay among the granite boulders. The ever present Coltsfoot (*Tussilago farfara*) straggled along the roadside even at this high level, but did not seem half so irrepressible or at home as in lower regions. We did not finally lose sight of it till we descended the Maloggia Pass into Italy. The modest British Eyebright (*Euphrasia*) here appeared as a handsome erect and many-branched plant, 6 inches high, bearing plume-like sprays of many-pencilled flowers, much larger than we are accustomed to see exhibited by the same plant in our lowlands. Our destination was Pontresina, which we reached at six p.m., about two hours' ride beyond Ponté. The situation of the village is most striking. It lies 6,000 feet above the sea at the junction of two streams, issuing respectively from the Rosegg and Morteratsch Glaciers, the end of the former being 4 miles, of the latter 6 miles from the village. The vegetation is wonderfully varied and profuse. The forests cease 1,000 feet above the village, and are composed entirely of Larch and Siberian Cedar (so called, or rather mis-called, for it is the Pinus Cembra). A few bushes

of Juniper and Cotoneaster are the only noticeable shrubs, but flowers are almost innumerable, and early in the season they must indeed be delightful. The meadows round the village were still rich with Meadow Safron (*Colchicum autumnale*), Dianthus (a large pale variety, reminding one of Hedewigii, but with a delicious fragrance of Honeysuckle), Campanulas, and Asters; an orange-coloured Composite, of a very pleasing tint, was also conspicuous. The woods are carpeted thickly with *Rhododendron*, *Pyrola*, *Linnaea borealis*, and Blackberries; and, above the tree level, the rocks are fairly wreathed and encrusted with such plants as *Saxifraga pyramidalis*, *oppositifolia*, *Rocheliana*, &c., *Sempervivum arachnoidum* and *chrysanthum*, *Epilobium* *Dodonnei*, *Primulas* of many sorts, *Azalea repens*, *Crowberries*, and *Campanulas*; while the Scottish Heath or Ling maintains a thrifty life to the very verge of eternal snow—not, however, as we are accustomed to see it, clothing whole mountains in soft purples and russets, such as no other plant can give, but in stunted starveling tufts. We had not time to explore the Rosegg valley, but confined ourselves to that of the Morteratsch, the eastern side of which, being less densely wooded, appeared richest in flowers, especially where the debris forms a well-marked line with the vertical limestone face from which it has fallen. The Val del Fain, or Valley of Hay, opens to the eastward at the head of the Morteratsch Valley, near the summit of the Bernina Pass, 7,000 feet above the sea. It is well named Valley of Hay, for never did I see so many square miles under the scythe. The treeless mountain lawns are smooth enough (though not level enough, of course), for tennis, broken here and there with masses of rock and little thickets of *Daphne* *Neoumum* and *Alpine Rose*. Both of us being Scotchmen, we involuntarily exclaimed, "What magnificent golf-links!" an expression that conveys a good deal of description in a few words to our fellow-countrymen. Through the centre of this elevated valley, closed at the upper end by the bare vertical walls of the Langard Range, and at the lower end by the dazzling snow-fields of the Diavolezza, a mountain torrent, clear as glass (lower down it receives the milky turbidity of the Morteratsch Glacier), has cut its way deep through a bed of primitive limestone. The walls of this gorge or canon are thickly clothed with a truly Alpine vegetation. We secured a quantity of bulbs of Lilies (which, I fear, will for the most part turn out to be pomponium) and other kinds. Gentians, from the large yellow lutea to the dwarf *bavarica* and *verna*, were very abundant. The gracefully-tufted seed-vessels of *Anemone alpina* waved over the short crisp turf, as those of *A. Pulsatilla* do on the chalk downs of England; and, mingled with these were seed-vessels of a genus, so singularly alike that it was only by looking at the root leaves that they could be distinguished. We obtained also some roots of a pretty hairy Campanula, with drooping bells of pale blue. But our most showy prize was half-a-dozen stout tufts of the much-extolled Edelweiss (*Gnaphalium Leontopodium*), of which we found a mass on the cliff overhanging the stream. To wear a bit of Edelweiss of your own plucking in your cap is reckoned a sort of certificate of your matriculation in Alpine climbing. It is so much sought after by tourists and natives—by the latter to be sold to the former—that it has disappeared from most accessible places near the villages, so we considered ourselves in luck when we came upon this bed of it. The plants of it which I brought home are spending the winter, not, as heretofore, in a snow wreath, but in a cold frame. To all fellow-lovers of flowers who visit the Engadine I would say go in June, take an air-tight tin case, a geologist's hammer, and a collector's trowel, and you will be amply rewarded. But do not appropriate any of the tempting little seedling Pines in the forests, for there is a wise decree in this canton that for every Pine so stolen detection entails a fine of 50 francs.

SALMONICERS.

Renovating Unhealthy Camellias.—Last season I set about growing Camellias, my stock of which consisted of two dozen plants. They ranged from 2 to 4 feet in height, and the whole scarcely produced a dozen flowers. The appearance of the plants being anything but promising, I removed the old soil from the back of our late Peach-house 1 foot deep—or perhaps more—put in rubble for drainage, and planted the Camellias close to the back wall with their root soil intact, giving them good holding-loam. They have grown well, and I have this season a good crop of flowers.—G. B.

IVY NOT INJURIOUS TO TREES.

BEING a devoted admirer of Ivy, allow me to offer the following remarks, which I hope may tend to induce your readers to use their own observation with regard to this beautiful and invaluable climbing plant, and not be led away by the repetition of remarks and assertions which lead to its destruction on ill-founded accusations. Ivy does not extract nourishment from trees. In a young state it is furnished with little soft feelers, by which it is enabled to cling to the bark and grow upwards. As it advances in age, these appliances die away and wholly disappear, and the stem of the Ivy has no more to do with the tree than a rope would have loosely coiled round it. Anyone may then pass their hand between the stem of the Ivy and that of the tree around which it coils, and that it does not injure the growth of trees, excepting when it becomes too heavy for the boughs on which it rests, I can prove from numberless instances; but I will only name two of the most remarkable. More than fifty years ago, Ivy was planted at the foot of an Apple tree, in a flower garden (now in my possession); the Ivy flourished, and made the tree a complete evergreen umbrella, which it is to this day, and yet, notwithstanding neglect as regards pruning, which would have been desirable to lighten the weight of Ivy from the upper boughs, that Apple tree flowered and bore annually, and still flowers and has borne fruit to a comparatively recent period. I do not adduce this instance with any idea of recommending the use of Ivy for increasing the produce of the orchard, but I do so to prove that it cannot impair the vitality of a tree, if an Apple tree can flower and bear for the greater part of a century, having been loaded with Ivy for more than half that period. Another instance is that of a Chichester Elm, also in my grounds, the rapid and fine growth of which elicited the wonder of the late Sir William Hooker. This tree has only been planted between thirty and forty years, and for size, height, and beauty it is the admiration of all who see it. Ivy was planted at its base at an early period, and has grown with its growth; the stems of the Ivy are now as thick as small cables, and between them and the tree, which it adorns with its evergreen foliage, at the present season when its natural leaves have fallen, there is a complete hollow. Ivy is also unrivalled in its wall-drying qualities, and sometimes is the only cure for a damp wall through which rain is driven by wind, a fact of which anyone may convince themselves, by the continual appearance of cobwebs if Ivy is torn down from a wall. The small wall Ivy is a very slow grower, but an admirable preserver of stone walls; it does not go between the stones, but forms a strong network over the face of the whole.

A. LL.

Church Decoration.—The following is the way in which we decorated a Church in this neighbourhood. The wall behind the altar was panelled and dressed with green Box or Yew, the angles and centre being Golden Holly. On this we fastened bunches of berries, the effect of which, backed up by the yellow leaves, was strikingly beautiful. On the sides of the panels, half way between the corners, we put clusters of yellow-berried Holly, which, on the dark ground, looked well, the position of the different-coloured berries and leaves being reversed in each alternate panel. Elsewhere, the panels were trimmed with silver-leaved Holly, mixed with common small wild Ivy, which was allowed to run gracefully, more or less, into the panels. In this case, no berries were used. Behind the altar was a cross, covered with green Moss, with very small Ivy embedded in it, and dressed with eight fine Eucharis flowers, viz., two at the base, four up the middle, and one on each side, forming a chaste and beautiful centre-piece.—JOHN GARLAND, *Killerton, Exeter.*

Deranged Thermometers.—The directions for adjusting registering thermometers which may have become out of order, as given at page 276, Vol. VIII., of THE GARDEN, apply only to the horizontal spirit minimum self-registering thermometers; the upright maximum and minimum instruments referred to by "Enquirer" (see p. 537, Vol. VIII.), which are filled partly with alcohol and partly with mercury, are too complicated and of too delicate a nature for any but a skilled workman to get right when once out of adjustment. The reason why one side reads higher than the other is that the thermometer, which is constructed for use only in a vertical position, has been laid down, and the two fluids have thus been displaced. "Enquirer" also complains that the index now follows the fluid instead of remaining in the tube at the maximum or minimum points, or requiring the aid of a magnet to move it in the tube, as originally was the case. This defect arises from the gradual loss of elasticity of the human hair (used as a spring to retain the index in the tube), by exposure to the action of the sun's rays. These thermometers should be placed strictly in the shade, as none but mercurial thermometers will resist the sun's heat without risk of being put of adjustment.—NIGRETTI & ZAMBRA, *Holborn Viaduct.*

NOTES OF THE WEEK.

— AT present, when the water-line of the Serpentine is 3 or 4 feet below the kerb stone placed around it, the folly of placing this stone edging there may be more fully seen than usual. Of course it must come away some day. The right margin here, as in most cases, is sand or gravel.

— AMONG choice vegetables now obtainable in Covent Garden Market are fresh Green Peas—forced indoors, of course. Asparagus may also be had; Truffles, from Hampshire, are tolerably plentiful; French Lettuces, Endive, Witloof or Chicory, and young Radishes are of excellent quality for salads; and winter Cucumbers may also be had in good condition.

— THERE is yet a wide field for raisers of new Apples of first rate quality and which will keep. Now, at the end of the year, specimens of our two best flavoured Apples, Cox's Orange Pippin and the Ribston, are obtained with difficulty, whilst the latest specimens are beginning to decay, and American fruit commands the best prices. Raising large cooking Apples, of which we already have too many, is needless work.

— AMONG the most beautiful of all pot-plants now brought to Covent Garden Market is the lovely little Siberian Squill, with drooping flowers of the clearest and most vivid blue colour imaginable. We have previously alluded to the charming pots of scarlet Tulips, intermixed with Lily of the Valley and Maiden-hair Fern now to be seen in the market, and we hope to see this Squill used in the same way. Indeed, nothing could well be prettier than pots of Lily of the Valley and tender young Ferns, neatly but not too regularly margined with this beautiful little Alpine bulb.

— IT is proposed to hold, in connection with the Westminster Aquarium, which is to be opened to the public early this month, a series of flower and fruit shows on the following dates—April 12th and 13th, Forced Rhododendrons, Azaleas, &c.; May 10th and 11th, Roses in pots, Azaleas, Palms, and Decorative Table Plants; May 30th and 31st, Grand Exhibition of Plants and Fruit; July 5th and 6th, Great Rose Show and Dinner-table Decorations; and October 4th and 5th, Great Fruit and Chrysanthemum Show. The amount offered in prizes at these exhibitions is £2,500, the prize money to be paid on the first day of the show.

— WE have frequently alluded to the rare Orchids which now find their way to the florists' shops in Covent Garden, and it is with pleasure that we see glimpses of the time when these plants shall be obtainable by anyone who cares to grow them. *Cypripedium insigne* is now sold as an ordinary decorative plant, and this week we have noticed flowers of the beautiful *Piiuma fragrans*, one of the purest and sweetest of all white-flowered Orchids, Rosel's, Pescatore's, and the Alexandrian Odontogloss; also the tiger-spotted species (*O. grande*), *Oncidium chrysothorum*, *O. tigrinum*, *Lælia anceps*, *L. autumnalis*, and *L. furfuracea*, to say nothing of a whole host of Lycastes and Dendrobis of the commoner kinds.

— MR. JAMES BARNES writes to us, as follows, respecting some trees of the Cloth-of-Gold Rose, in Devonshire:—"Near Mr. Ella-combe's vicarage, at Clyst St. George, lives a small tradesman, a great Rose fancier, who has growing at the end of his house the finest Cloth-of-Gold Rose tree I have ever seen. It covers the whole gable end of his house, has a stem as thick as one's arm, and produces flowers in such abundance as to surprise all who see it when in bloom. The only attention which it receives is pruning out the weak wood and tacking in the long, strong shoots full length. Another Rose tree, of the same variety, close to Exmouth, grows up the side of a house to a height of from 30 to 35 feet, the growth being rough and rambling. This tree makes young wood 10 and 12 feet in length, and when loaded with blossoms, which it annually is, its appearance is strikingly beautiful, intermixed with other climbers.

— A MONOGRAPH of the genus *Adiantum*, by A. Keyserling, appears in the "Mémoires" of the Academy of St. Petersburg, Vol. XXII., part 2 (1875).

— IN the limited space afforded by our index supplement we, this week, have had little more than room to hint at the great amount of attention that Mr. Darwin has throughout his life given to plants, and to his claims to be included among great gardeners. He has little affinity with the numerous botanists who concern themselves with the names of plants only. He has tried to fathom some of the mysteries of plant life and has often succeeded, and often pointed to the direction from which light will probably come. Many of his most interesting experiments were carried out with living plants in his own garden in Kent, and in his own greenhouse.

THE INDOOR GARDEN.

ROCKY SCREENS IN CONSERVATORIES.

It is often desirable to hide a wall or some other unattractive surface or objectionable feature in a winter garden or conservatory. How to do this effectually and gracefully is often attempted in the garden. Happily, it has often been most effectually done, and we this week engrave a photograph of a rocky screen erected in a conservatory near Hampton Court, by Messrs. Weeks & Co. In this case a view of certain out-houses, &c., necessitated a screen, and a rocky screen erected by Mr. Pulham is, as many of our readers know, a beautiful object, especially when Ferns and Mosses begin to feel at home on it, and free-growing climbers fall from point to point. By leaving interspaces for plenty of soil, fine-leaved plants may be well grown, their massive leaves contrasting admirably with the delicate grace of the Ferns and Mosses. In a conservatory or glazed structure of any kind, where the atmosphere is, to

large baskets with the Pelargonium family. The bottom of each basket was lined with fresh green Moss, and large plants of the Ivy-leaved varieties, such as L'Elegant and Willisii roseum, were planted at the edge, and pegged over the outside of each. The centres were then filled with free-flowering Zonals, scarlet, pink, and white, and a few plants of tricolor and scented-leaved varieties. They were hung up out of doors under the partial shade of trees for a month until well established, when they were removed to their light, airy, winter quarters at the top of a large conservatory; since then they have been continually glowing with splendid trusses of bloom. The many beautiful varieties of Ivy-leaved Pelargoniums now in cultivation show to greater advantage in this way than under almost any other circumstances. As soon as the under part of the basket is covered the shoots should be allowed to depend naturally, when their graceful habit will greatly add to the beauty of their showy, but stiff-habited, Zonal brethren. The good or bad effects of baskets depend greatly on the graceful and natural manner in which the plants are arranged. Great

Rocky Screen in a Conservatory.

some extent, under control, it is easy to sustain an abundance of graceful plant life on a rocky screen, particularly if it is made after a fashion that allows a good deal of soil to be placed here and there. But, even without any soil, numbers of plants root freely and live healthfully on tufa, and even on hard rocky surfaces.

PELARGONIUMS AS BASKET PLANTS IN WINTER.

In lofty conservatories the addition of hanging baskets considerably enhances their attraction. One condition of success in growing basket plants is the careful selection of plants that will really flourish in the strong light and dry atmosphere of such a situation. After trying several experiments, I must give the pre-eminence to the several varieties of Pelargoniums, both for the length of their period of flowering and for the great variety of colour, both in leaf and flower, which they exhibit. About the middle of August last we filled several

care must be paid to the watering of all basket plants; they are much exposed to drying currents of air, and therefore suffer sooner from lack of moisture than plants on the floor or stages of the house. While speaking of the free-flowering properties of Pelargoniums for winter decoration, allow me to add that most cultivators are very differently situated to your correspondent, Dr. Denny (see page 515, Vol. VIII.), who, like many enthusiastic cultivators of some particular class of plants, thinks his own hobby worthy of more attention than others feel disposed to pay to it. While fully admitting all that your correspondent can urge in favour of the Pelargonium as a winter-blooming plant, I would remark that, in furnishing conservatories at this or any season of the year, one of the things to be avoided is too great a preponderance of any one class of plant. That course is calculated to weaken the effect of a conservatory, and is in fact a repetition of the evils of our summer bedding system.

JAMES GROOM.

Henham.

THE FLOWER GARDEN.

THE POLYANTHUS.

IN old books on the cultivation of the Carnation and other florists' flowers, published in 1822, I find that in treating of the Polyanthus, a list of no fewer than forty-two named varieties of the fine old gold-laced type is given; and of this number, as far as I can learn, only one variety was in cultivation thirty-five years later. I got this information through searching published lists of that time. The most complete list that I can lay my hand on gives only thirteen varieties, and of these perhaps not more than half a dozen are now in cultivation. In the south of England, named Polyanthuses are almost unknown, except in a few rare instances, but they can be met with in Lancashire and Yorkshire, though by no means in plenty, even in districts so eminently suited to the successful cultivation of the Polyanthus. At the exhibition of the National Auricula Society at Manchester in April last, it was noticeable that, while Auriculas, both show and Alpine, were produced in large numbers, the former especially, only a very few Polyanthuses appeared in the classes set apart for them, and they came from only two or three exhibitors, and consisted of Sanders's Cheshire Favourite, Cronshaw's Exile, and Bullock's Lord Lincoln. A really good Polyanthus—good in so far as it answers to the requirements of the standard of quality set up by the old florists—is a very beautiful flower. Of the forty-two varieties mentioned by Hogg, what has become of them? I should imagine that a large number of them died out because of the higher quality found in the flowers that succeeded them; but of the varieties that superseded them, how many could now be found? I am doing my very utmost to get a collection, and have already obtained some three or four, found in a list of the best varieties given in 1856. If half-a-dozen or so can be got together, a good groundwork would be formed, out of which to produce some new varieties. The best estimate of properties in a good laced Polyanthus was set forth by the late George Glenny, as follows:—Of the pip. 1. The single pip or flower should be perfectly flat and round, and be slightly scalloped on the edge, and three-quarters of an inch in diameter. 2. It should be divided in six places, forming six apparent flower leaves, each of which should be indented in the centre to make it a kind of heart-shaped end; but the divisions must not reach the yellow eye. 3. The indenture in the centre of the apparent flower-leaves should be exactly the same depth as the indenture formed by the union of these flower-leaves, so that it should not be known by the form of the flower which is the actual division and which is the indenture—in other words, which is the side and which the centre of the flower-leaf; and all the indenture should be as slight as possible to preserve the character. The tube should be one-fifth of the whole width of the flower, and stand up at the edge above the surface of the yellow eye. 4. The flower should be divided thus: the yellow tube in the centre being measured, the yellow eye around the tube should be the same in width as its diameter; and the ground colour of the flower should be the same. Or draw, with the compasses open to the sixteenth of an inch apart, a circle for the tube or centre; open them to three-sixteenths, and draw another circle for the eye, then open them further to five-sixteenths, and draw a circle for the ground or dark colour. Beyond these circles there is a yellow lacing, which should reach round every flower leaf to the yellow eye, and down the centre of every petal to the eye, and so much like the edging that the flower should appear to have twelve similar petals. The ends of these twelve should be blunt and round like so many semi-circles, so that the outline of the circle should be interrupted as little as possible. 5. The tube should be nearly filled up with the six anthers, which are technically called the thrum, and the flower should not exhibit the pistil. 6. The edging round and down the centre of the leaves formed by the divisions should be of even width all the way, and universally of the same shade of sulphur, lemon, or yellow as the eye, and there must by no means be two shades of yellow in the eye. 7. The ground colour should be just what anybody likes best, but clear, well-defined, perfectly smooth at the edges inside, next the eye, to form a circle; and outside, next the lacing, a black or a crimson ground, being scarce, is desirable; but the quality of the colour as to clearness, rather than the colour itself, constitutes the property. Of the plant —1. The stem should be strong, straight, elastic, and from 4 to 6 inches in length. 2. The foot-stalk of the flowers should be of such length as to bring all the flowers well together. 3. The truss should comprise seven or more flowers, and be neatly arranged to be seen all at once. 4. The foliage should be short, broad, thick, and cover the pot well. To these rules Glenny also added some applying to the exhibition of pairs of plants, or pans of plants, as collections of more than two are termed. The pair, or pan if more, should comprise flowers of different and distinct colours, either the ground colour or the yellow of each being sufficiently different from the rest to be well distinguished. The whole should be so near of a height as to

range the heads of bloom well together. The great fault of the Polyanthus now, even among the best sorts, is that the divisions between the petals are so wide as to make the flower look starchy, whereas there should be no more gap where the division is than is in the indentation of the petal itself. To many these rules may appear needlessly minute, and even arbitrary; but when they are most displayed in any flower, the beauty of that flower is at once apparent. An ordinary Gold-laced Polyanthus grown in a border has many attractions; but one of the fine varieties, that has been subjected to pot culture, has the beautiful lacing which constitutes the chief beauty of the flowers most charmingly arranged.

History.

How the Gold-laced Polyanthus of the florists originated appears difficult to ascertain. Possibly, by means of some old books, its gradual development might be traced, and the time when it was first taken in hand by the florists discovered. In one of his interesting reminiscences, the late Dr. Horner, of Hull, who was a leading cultivator of the Polyanthus in his day, states that "the Polosanthus, Poly-anthus (many-flowered), is a direct descendant from the *Primula vulgaris*, the common Primrose; yet what a change have the labours of the florist wrought here!—so great, indeed, that we are compelled to resort to the more exact science of botany to assure us of its undoubted origin. For, not only has cultivation imparted to it a new as well as a distinct arrangement of colours, but the sessile stem of the Primrose has been converted into the scape, or elevated stem, bearing an umbel of flowers, as in the recognised Polyanthus of florists. That the Polyanthus is indeed thus derived, the florist is too often vexatiously reminded, in witnessing among his cherished hopes in a bed of seedlings, a fair sprinkling of Primroses, both plain and coloured; while the cultivated seed of the Primrose will not unfrequently produce coloured flowers, and that on an elevated stem." I have heard of an old florist, a great lover of these flowers, who regarded all except what we call "show Polyanthuses" as Primroses, whether they bloomed on single stems or in an umbel, and he distinguished the former as "single bloomers," and the latter as "cluster bloomers." From whatever it may have sprung, it is certain that succeeding generations of florists have brought into cultivation and largely improved the Gold-laced Polyanthus, and eventually named varieties, a few of which survive to the present day. Of late years named varieties of the Gold-laced Polyanthus have been raised and sent out round London; but a comparison with such fine standard flowers as Cheshire Favourite, Lancer, and Exile, shows how much below these they must rank when tested by the rules which constitute quality.

Cultivation.

The only sure guidance in the artificial cultivation of a plant is the observance of its natural condition and habitat; and where grows the Primrose, in its wild luxuriance, but in the shaded lane or woodland? And, though it is sometimes seen to adorn in the spring the sunny bank of a hedgerow, yet the summer's sun can visit it, even there it will be found that Flora has kindly sheltered her favourite amid the shadowing growth of others of her train. The Polyanthus, then, should always be grown in a cool bed or open border, which has an eastern aspect, or which is otherwise wholly shaded from the summer's sun, for it is most impatient of heat and draught, and, it may be added, of confinement and smoke also; and hence it can never be well grown in the immediate vicinity of large towns. This is Dr. Horner's experience, and it is quite in accordance with that of a great many others who have endeavoured to cultivate this flower. No mode of culture shows off the Polyanthus to better advantage than growing it in pots; at the same time, in order to succeed, it is a process requiring some care and attention. There was much more truth than appears on the surface in the remark of an old florist that "hard well-burnt unporous pots and thorough drainage" are essential to its successful culture; and 48 and 32-sized pots—using them according to the size of the plants—are the best for the purpose. So much for the size of pots for the Polyanthus. In regard to soil good fibry loam from a pasture, the top spit of which should lie by for a year or so till thoroughly decomposed, leaf mould, powdered charcoal, and dung from a spent Cucumber frame, well mixed together, the loam about one-half of the whole, is the best soil in which the Polyanthus can be grown. The usual rule is to pot up the plants for spring blooming about the month of June and July, though some do it as early as May; and when this is done, the plants should be quite shaken out of the soil in which they have been growing, and a good portion of the long stumpy tap root cut away, retaining only that part nearest the leaves that has plenty of young fibres. It should be borne in mind that the young or fresh roots of the Polyanthus are thrown out close to, and even among, the leaves, and, in consequence, when the Polyanthus is planted in suitable soil in the open

ground, and allowed to remain undisturbed for any length of time, the tap root gradually becomes of great length. At the time of this early summer potting, offsets are removed from the plants, and the treatment of these shall be dwelt on presently. In the act of potting the cultivator should form the soil in the pot like a cone, and on this the root stem of the plant should rest, with the roots hanging down on all sides; and in this way pot them, putting the plant pretty deeply in the soil, remembering what was just now stated, that the young roots come from about the leaves. Bear in mind that it is always more easy to top-dress a plant, and by so doing bring it nearer the surface of the soil, than to lower a plant that has grown out of the soil. The latter difficulty can only be met by re-potting. After potting, water the plants freely, in order to settle the soil well about the roots. The plants should then be placed in a shady situation, in an old frame with a good ash bottom raised well above the surface of the ground; but at the same time they must have abundance of air. The plants will not need further watering till the roots begin to lay hold of the soil. It is well to protect the plants from heavy rains. In October the surface of the soil should be stirred, and if any green growth has accumulated, as sometimes happens, it should be removed, and replaced with some fresh soil. It is a usual practice to top-dress at this season of the year.

Wintering the Polyanthus.

This should be done in a cold frame, but the frame should be banked up on the outside with ashes, or earth, or leaves, to keep it warm in times of severe frost. The plants should be placed on bricks, inverted flower pots, or wooden frames, and be raised about a foot from the glass. By thus raising the pots, the air can freely circulate among the plants, which is of great value at this season of the year. Or the pots can be brought into a cold greenhouse, but placed on a raised shelf. Green fly is apt to affect the plants during the winter, and they should be looked over occasionally, and any insect pests removed with a camel's-hair brush. Slugs will sometimes attack the plants, and they must be looked after also. When frost is imminent, the great thing is to have the plants as dry as possible; and really they are much more liable to be injured by wet than by frost. The plants should therefore be kept moderately dry during November, December, January, and February; at the end of the latter month they will begin to push into growth, when more water may be applied. About the first week in March, the old practice is to top-dress the plants by taking away an inch of the surface-soil and substituting some rich compost. In removing the soil, care must be taken that the rootlets, which are pretty near the surface round the base of the plants, be not disturbed. After the top-dressing the flower-spikes soon put in an appearance; and, in order to have finely-developed pips, the old florists used to thin out the flower pips so as to leave about six outside ones. By the end of April the plants would be in fine flower and fit for the exhibition table. It is necessary at this stage to shade the flowers from the sun to preserve their colours, and to have them as fresh and the lacing as perfect as possible. After blooming, the plants should be removed to a northern aspect, and kept in the shade, but not under the drip of trees, and stand on an ash bottom, and here they may be at rest for the summer. The plants should be kept free from dead foliage, and the attacks of thrips and snails be guarded against. The soil about the roots should be kept moist, but not excessively so. A little top-dressing may be added during the summer, to induce the plants to root high up, and, as it sometimes happens that a tap root decays, the surface roots maintain the vigour of the plants. Any variety required to produce seed should have a hand-glass placed over it, if any extra protection is deemed necessary. It is the practice of some growers to turn the balls out of the pots about the beginning or middle of June, and without reducing them in any way, plant them out in a shady and well-drained border, where the plants will remain till they are re-potted and divided in August; and this brings me to the matter of offsets or root division.

Propagation by Division.

The Polyanthus can scarcely be said to throw off offsets in the same way as the Auricula; rather it throws up two or three or more strong crowns, according to the strength of the plants, and perhaps one or two smaller ones. The crowns should be divided, and the strongest potted up to flower in spring, as already directed, and the smaller crowns potted singly into small pots. The old florists contended that a single crown produced by far the finest flowers. As to soil, good sod-soil from an old pasture, to the extent of about two-thirds, enriched with old manure and leaf mould, the latter in good proportion; in such a mixture the Polyanthus cannot fail to do well. Though the leaf mould is not absolutely necessary, yet it will ever be found, both in respect of the Auricula and the Polyanthus, that whenever there occurs in the soil a little mass of decaying

leaves or sticks, there the roots will be most numerous and vigorous. Such practical hints on natural tendencies the observant florist ever treasures up, and it is by their observation and application that he becomes a more successful cultivator than his fellows. While I have been treating of the old Gold-laced Polyanthus, I must not overlook the claims of the Fancy kinds, as they have a great decorative value much beyond that possessed by the Gold-laced varieties. They are all very vigorous growers, and do not possess the delicacy of constitution peculiar to many of the high-bred Gold-laced varieties. In point of colour they range from pure white to deep purple, the individual pips are of great size, and the trusses correspondingly large. They well deserve to be taken in hand as exhibition plants, and this will no doubt be done before long, as some fine named varieties have been distributed. Among them are The Bride, white; Etna, magenta-crimson; Field Marshal, velvety-crimson; Jessie, bright rosy-violet; Viceroy, sulphur; and Warrior, rich shaded magenta.

Cultivation in Beds in the Open Ground.

The proper time for planting is the last week of July, the end of the period of the summer rest, and when the old plants have attained such maturity and size as to admit of easy division. It was always considered that this period of planting should be strictly observed, in order that the plants might have all the advantages of their natural autumnal growth, thereby becoming thoroughly established in the soil before winter, and ensuring a vigorous bloom in the spring, as well as obviating all chances of disease or death from the severity or changes of weather in their winter season of rest. "The plants should be carefully divided with a sharp knife, or neatly detached with the fingers if nearly separated, but not slit or torn up, though such injurious and unscientific practice has by many been recommended, on the whimsical theory that a lacerated wound in the Polyanthus or Auricula is sooner healed than an incised one! Lacerated wounds, both in plants and animals, are most dangerous." So wrote, in sober prose, one of the fine old Polyanthus cultivators of the past generation. In the case of planting in beds, as in pots, the main or tap-roots should be shortened to within an inch of the insertion of the leaves, that a few of the young and more vigorous roots only be retained. At the time of planting out, the roots should be divided as recommended in the case of plants potted, as previously set forth. The method of planting is perhaps the most important feature in the culture of the Polyanthus; it must be set deep in the soil. Having made a hole in the earth with a trowel, place the plant so deep therein that the very crown of the root is covered one inch with soil, for it is from this upper part that the young roots proceed; and hence it is essential that they at once meet with earth in which to grow and ramify. If this condition be not afforded, the plants will either dwindle and damp off from the perishing of these young roots, or we shall witness stunted plants, with bunches of curly fibres, struggling to reach the surface of the earth—a very common sight in a neglected border of Polyanthuses. The plants should be placed in rows, and be 8 inches apart each way. When planted thoroughly water the bed, and the plants will require no further care, unless a spell of dry weather sets in; and then, if the beds occupy an exposed position, they should be occasionally watered, and some leaf mould scattered over the surface to keep the soil cool and moist. All coverings in the way of protection during winter are wholly unnecessary, and even hurtful. In the spring the surface of the bed around the plants should be made neat and clean, and when the flower stems have risen and the flowers are about to expand, they should be protected by an awning from the rain or sun, or the freshness and richness of their colours will be deteriorated. If required for the purposes of exhibition, or for ornamenting a cool, airy greenhouse, or even a cold frame, they may be readily taken up, without risk or injury, with a ball of earth, and put into common-sized Auricula pots, being at the same time liberally supplied with water; when no longer required for such purposes, they must again be returned to the bed. When the bloom is over, and during the summer months, the plants still require no care beyond the ordinary attention of keeping them clean, and the earth moderately moist by occasional watering; for if the Polyanthus be subjected to excessive drought the plants are extremely apt to become infested with red spider, as indicated by the yellow mottling of the foliage.

Raising from Seed.

Seed should be sown in August soon after it is ripe. The great advantage derived from doing this is that the plants become of good size by spring, and flower the following spring finely, displaying their characters to the best advantage. The seed should be sown in pans or shallow boxes, and, as soon as large enough, pricked off into 48-sized pots, in some good soil, about six plants in a pot, and grown on strong during the summer. As a matter of course, when the

seedlings flower only the very best should be retained and the indifferent ones thrown away. A large number may be raised from seed taken from the very best flowers, but only a very few of them are likely to have all the characteristics of a first-class Gold-laced Polyanthus. Seed of the fancy varieties will produce something much more satisfactory, because in this strain the grower is not confined to one particular type of flower. Quo.

Lilium giganteum in Scotland.—Perhaps it may interest some of the readers of THE GARDEN, to know that this magnificent Lily grows out of doors, and is quite at home even farther north than Edinburgh. Handsome, no doubt, as was the specimen that grew in the garden of Professor Owen, yet I am happy to inform those interested in Lily culture, that two specimens of this Indian Lily grew on the banks of the Gareloch, that even surpassed the one at Sheen. In the summer of 1874, twelve bulbs were planted in a shady Rhododendron border, facing the west (previously they were grown in pots for the conservatory, but never gave satisfaction), and this summer I was pleased to see two flower-stems spring up. One grew to the height of 9 feet, and bore eleven fine flowers 7 inches in length; 6 inches from the ground the stem measured 7 inches in circumference. The other grew to the height of 7½ feet, and had ten flowers. I gave the plants no protection whatever from frost, and last winter was an unusually severe one in the west of Scotland. —D. McLEAN, *West Shandon Gardens.*

Roses in Spring.—I am anxious to have some good Rose trees, that will blossom in the spring, having no greenhouse or conservatory to fall back upon. Hitherto, I have only been able to have a few window Roses, and the disadvantages of a poor aspect to contend against. If some of the authorities on Rose culture, as Mr. Reynolds Hole, with his usual gallantry, would kindly assist a lady amateur by giving her a few hints as to what kind of frame to construct, the kinds of Roses to purchase, and when to prune and plant them, she would feel deeply grateful for the kindness.—M. L. W. [Though I am fully occupied by clerical work, I am constrained, by a summons from a lady's voice, to pass for a few minutes "from grave to gay," and to inform "M. L. W." that she may grow beautiful Roses in a frame during the season of spring, if the said frame is made frost-proof by artificial heat, for which purpose a boiler and pipes with hot water are by far most efficacious. My Rose pits are 2 feet 6 inches high at the back, and 1 foot 6 inches high in front (brickwork and woodwork inclusive), above the ground, and 1 foot deeper within. The sashes are 6 feet by 4 feet 6 inches. I place Dwarf Roses, either on their own roots, the Briar (seedling Briar preferred), or Manetti, which have been re-potted, or taken up from the open ground and potted, and pruned in October in the pits, accordingly as I want the flowers, from this time (my first batch are now in healthy foliage) until February, so that I may have Roses in March, April, and May, before the garden Roses bloom. I have given a select list of the varieties which do best in pots in the last edition of my "Book about Roses;" but if "M. L. W." has it not, she may safely venture upon nearly all the more robust kinds, such as Marquise de Castellane, Etienne Levet, Baronesse Rothschild, and others. Let her diligently obey, as laws which, like those of the Medes and Persians, alter not, the following injunctions—to force her Roses as gradually as she can, avoiding variations of temperatures; to give air whenever the air is neither rough nor cold; to destroy insects by mild and frequent fumigation.—S. R. H.]

Tree Ivy in Shrubberies.—By way of change, I was induced some years ago to try Ivy in a kind of wilderness or grove that we have here. It occurred to me then to collect some large roots of trees that had been felled, and on which some of the fine roots had been allowed to remain. Of these, which were similar to those sometimes used in the construction of Ferneries, three or four were laid together roughly, and in no arbitrary form, to a height of from 2 to 4 feet. Some plants of Ivy were then planted all round and twisted in between the small roots; and with very little attention afterwards they were soon covered over. The result doubly repaid for the labour by the improvement that was effected in the appearance of the shrubbery, which was planted with common kinds of shrubs, chiefly evergreens, with a few flowering kinds; whilst the border next the path contained various kinds of dwarf Vinca in masses. Between these are beds of Lily of the Valley, common Ferns, Daffodils, Primroses, with other spring flowers, which produce a very pretty effect. An irregular avenue of Beech trees runs through the centre near the path, and all the plants seem at home under a grateful shade. I find that the Irish Ivy answers best, as it grows better and covers more quickly. One root I planted with a small-leaved kind, but it has not done so well. I have not tried the variegated kinds, and I fear they would be too delicate.—W. DIVERS, *Wierton, Maidstone.*

DISEASE AMONG LILIES.

Mr. A. S. FULLER, tells a sad story in "Moore's Rural," of the destruction of a large collection of Lilies, by a disease which he fails to account for. It is not often that disease attacks our hardy ornamental plants, although the agriculturist frequently suffers severe losses from rust, smut, and mildew in his grain fields, or rot among the Potatoes. Ten years ago Lilies were an especial favourite of mine, and I would scarcely dare tell of the investments made in rare kinds imported from abroad. But the Golden-banded Lily of Japan at £6 per dozen and Liliun Browni, at a no less price, were two that came in for a goodly share of attention. But it is not necessary to consult my cash book in order to arrive at the fact which I desire to place on record at this time. I will say, however, that at a certain period, not more than half-a-dozen years since, 10,000 Lilies bloomed in my garden, and of the various species and varieties found in different parts of the world. There were in one bed 5,000 of the Golden-banded (*L. auratum*) all in bloom at one time, and in another 1,000 of the long-flowered white (*L. longiflorum*), also about the same number each of the showy speciosum or, as it is more usually termed, lancifolium. Then there were half-dozens and dozens of the more or less rare kinds scattered about to make the collection complete. My success in the culture of this showy family of plants was so great that I began to think strongly of devoting my entire grounds to Lilies, and of eventually entering the market with the produce; but alas! there is usually an end to air castles as well as those of more substantial structure. The next season, after my grandest supply of Lilies, I noticed that some few varieties showed signs of disease; the stems and leaves assumed a rusty appearance, and small black spots appeared on the bulbs, as well as on parts above ground, such affected plants failing to bloom, and the bulbs in autumn were soft and immature. I lifted the bulbs and re-planted in new beds, applied ashes, lime, and various other substances, in order to stay the progress of this disease, if possible; but all to no purpose. It continued to spread, taking in its course even the old Tiger Lilies, as well as the common wild species which had been transplanted from the fields and swamps near by into the garden. Bulbs taken up from the garden and placed in my greenhouse immediately assumed their wonted vigour and health, and not a sign of disease has ever appeared upon a plant grown in pots; but of my fine collection left out not a half-dozen bulbs survive. The bed once occupied by auratums has been planted with evergreens, and last summer I saw two or three stray plants blooming, half hidden among the dense foliage of some Arbo-vitæ, and these, with one lone double Tiger Lily, are the only representatives left in my grounds of the noble family of plants which a few years since made large demands upon my purse and time, as well as excited my admiration and pride. Now, it is not pleasant to recount one's failure in such matters; still, it is just possible that by recording the disaster which followed my "Lily fever" some novice in floriculture will be put on his guard, not to count chickens until they are out of danger of the pip. Perhaps it will be well to state that my land is a light, sandy loam, well under-drained naturally; consequently, if the Lily disease was caused by incongenial soil, it must have been on account of its being too warm and dry. But the Lilies did thrive remarkably well for a half-dozen years or more, and I think the rust was introduced among the imported Japanese sorts, as no sign of any disease was ever seen among my Lilies until the latter were purchased and planted out.

A New Race of Zinnias.—The "Gardeners' Chronicle" describes some new double Zinnias raised on the Continent, which show considerable variety of colour, and represent four diverse types, differing, it would seem, in habit and stature. One of them, *Z. Darwinii* major, is described as of compact branched habit, with large globular flower-heads. These flower-heads reached us in a somewhat shrivelled state, but they were densely double, and measured fully 2 inches across and about 1½ inch in depth. The leaves (those only just beneath the flowers being seen) were sessile, triangular-ovate with an acute point, and three-nerved. The colours of the flowers included scarlet, orange-scarlet, orange-yellow, rosy-purple, sulphur, and white. *Z. Darwinii* vittata had striped flowers, including such combinations as white with purple flakes, purple with white flakes, yellow with crimson flakes, sulphur with purple flakes, &c. Others labelled *Z. Darwinii* were described as being of dwarf compact-growing habit and extremely free-flowering; the flower-heads were conical and imbricated double, and differed from the others in being smaller, about 1½ inch across and 1½ inch deep, very full double, with a high centre; the colours were considerably varied, and included white, sulphur, yellow, orange, and two or three shades between purple and crimson. *Z. Darwinii* pyramidalis vittata is taller in habit, growing like an inverted pyramid, and the forms sent

were mostly pale-coloured, more or less flaked. This new form of *Zinnia* is, we learn, a hybrid raised between *Z. Haageana* (mexicana) and *Z. elegans*, and is said to be very constant. It is abundantly distinct in character from the beautiful double forms of *Zinnia elegans* now becoming popular, and, so far as can be judged from cut flowers, appears to be quite an acquisition for the flower garden. With the *Zinnias* came two forms of garden Beet with coloured foliage, not of any special merit. The best had the leaves smooth and of a glossy somewhat liver-coloured red; the other had the leaves rough and of a dull purplish hue.

A BLUE DAISY.

To our ordinary Daisies, now so much used for spring decoration, this will prove a valuable addition. It is described as being one of the commonest of spring flowers in different parts of Morocco, abounding in fields with a rich soil on the hills near Tangier, and occurring in great profusion by the water courses of the valleys of the Greater Atlas in latitude 31°, at elevations of from 4,000 to 11,000 feet. This blue variety, first found by M. Balansa during his journey in Morocco in 1867, has been introduced to this country by Mr. Maw, and it is already tolerably well known in our best gardens. The best specimen of it which we have yet seen was one in the herbaceous

Bellis rotundifolia ceruleascens.

border at Chiswick in the autumn of the present year, a dense little tuft 9 inches in diameter, bearing twenty-one fully-expanded flowers. It appears to like a deep rich soil, and to require no particular attention. It is best propagated by careful division in the spring. B.

Sedum villosum.—Though this pretty species is not uncommon by the sides of Alpine rills in Scotland and the north of England, it is, I believe, not generally known in the southern parts of our island. I saw it in great beauty growing in a shallow brook near to St. Moritz in company with Sundews and Butterworts. The plant itself was immersed in water, the panicle of deep lilac flowers alone rising above the surface, and resting on the water. Its habitat seemed so much at variance with the succulent leaves of the plant, that I thought it could hardly be a *Sedum*! A viscid glandular pubescence clothes the upper parts of the plant. Koch speaks of it as a biennial, and he describes the petals as roseate, with a purple dorsal streak. In drying, I find that the colours have become darker in hue.—PETER INCHEBALD, *Hovingham Lodge, York.*

Saponaria Ocymoides on the Continent.—Of all the *Saponarias* I have seen, during my visits to the Continent, none is so beautiful and conspicuous as this species. It occurs abundantly in the eastern parts of Switzerland—such as Tyrol and the Grisons—where it seems to delight in a loose and stony soil. It is as dwarf in habit, and as free to flower as *S. calabrica* itself; but its flowers are larger, and deeper in colour, and in warm, sunny nooks, the little

tufted plants are covered with flowers, so that the leaves and stems are quite hidden by them. It must be an excellent plant for rock-work, for I noticed that it soon seizes upon freshly-built earth-work, insinuating itself into the crevices of the stones, and hanging down in dense masses of deep rose. I first saw it in the *Albula Pass*, and at the time I wondered what it could be, mistaking it, as so many do, for a *Lychnis*, but on gathering it I soon found out my error.—PETER INCHEBALD, *Hovingham Lodge, York.*

POLYGONUM CUSPIDATUM COMPACTUM.

THIS is a beautiful form of a well-known species which is really more distinct in character, for ornamental purposes at least, than many of the so-called species introduced to us. The writer observed the plant recently in the nursery of Mr. Parker, at Tooting, and was very much pleased with its beautiful compact habit and its floriferousness. *P. cuspidatum* is tall and straggling in growth, with a thinness of foliage and looseness of flower-spikes which leaves much to be desired in it for ornamental purposes. The dwarf variety is, however, one of the most ornamental autumn-flowering plants that I have seen for some time. It is the counterpart of the tall form, with the stems compressed to about a foot in height. Along with this shortening of stem there is little or no reduction of the number of joints, and consequently the foliage and flowers are much more dense. The leaves are shorter and narrower than they are in the normal form, and the flower-spikes are shorter, more crowded, and nearly erect; but the colour is the same in both forms,—a beautiful straw colour. It flowers during September and October. The plant originated in Mr. Parker's nursery some time ago, on a spot where the tall form had been previously grown, and luckily it was not destroyed, under the supposition that it was the ordinary form, until its superior characteristics were observable. It stands in need of a distinctive name, and I would suggest that it should be *compactum*, as being the most suggestive of the desirable features of the tall form being joined without diminution to a very compact habit. It is a beautiful plant for the herbaceous or mixed border, and for rock-work.—"The Gardener." [We regret to see any attempt to judge such plants as the stately and valuable *Polygonum cuspidatum*, from a florist's point of view. It is the fine free habit of this giant *Polygonum* which makes it effective in the picturesque garden. Mr. Parker's plant may be a desirable one, and an interesting variation, but we may state these facts without undervaluing one of the best hardy plants ever introduced. As to its being "out of place in select positions," Mr. Gibson used it with good effect at Battersea, in the sub-tropical garden. As a lawn plant, singly in small groups, near shrubberies, it is very fine in rich soils.]

Newspaper Bye-Laws.—1. Be brief. 2. Be pointed. Do not write all around a subject without touching it. 3. State facts, but do not stop to moralise. Let the reader do his own dreaming. 4. Eschew preface. Plunge at once into your subject, like a swimmer into cold water. 5. If you have written a sentence that you think particularly fine, draw your pen through it. 6. Condense. Make sure that you really have an idea, and then record it in the shortest possible terms. 7. When your article is completed strike out nine-tenths of the adjectives.

Atoms.—By four different modes of argument derived from different parts of science, and pointing mainly to the same conclusion, Sir W. Thomson has shown that the distance between two molecules in a drop of water is such that there are between five hundred millions and five thousand millions of them in an inch. He expresses that result in this way—that if you were to magnify a drop of water to the size of the earth, then the coarseness of the graining of it would be something between that of cricket balls and small shot. Or we may express it in this rather striking way. You know that the best microscopes can be made to magnify from 6,000 to 8,000 times. A microscope which would magnify that result as much again would show the molecular structure of water.

Billings on Bonnet Flowers.—Flours are worn this season quite natch on bonnets. I saw a luv of a hat last week at Madame Frisky's. It lookt natch like a bokay for a target excursion, presented by sumalderman to the constables of his ward. There waz Sundaftons and Pond Lills, Hollyhaws and Dandyilions, enuff to stok a forty akker garden. I waz told that the bonnet waz the very cream ov style, and the price waz a mere song, only seventeen pounds. I wanted to buy the dear thing and set it out in my front yard and water it and see it gro, but it had been sold to a coal dealer's wife.

"THE show of the — Society was the best ever held since its organisation," is a sentence which should be "kept standing" in every well-regulated newspaper establishment during the flower show season.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Pelargoniums, Calceolarias, and Fuchsias.—Pelargoniums, intended for flowering early, will now have made considerable growth. Although, for decorative purposes, it is neither needful nor advisable to train them as is usually done when they are intended for exhibition, yet—in order to keep the shoots from becoming “drawn”—they should be well opened out, so as to admit plenty of light to those in the centre. All sticks, required for their support when in flower, should at once be placed to them, and the shoots tied thereto; for, later in the season, the soil gets filled with roots, and the insertion of the sticks then often causes serious mutilation. Fancy varieties should also have sticks placed to them; but they do not need so much support as large-flowered sorts. Such plants as bloomed latest during the past summer, and which were not cut down and shaken out until late in the season, will now require placing in their flowering-pots. These also will be better for being tied at once. The points of the shoots ought to be pinched out, which will have the effect of causing them to flower later, and thus form a succession to the earliest, which should not be stopped at all, except such as are young and very vigorous. Place them as near the lights as possible. The earliest-sown herbaceous Calceolarias should now be moved into their flowering pots. These rapid-rooting subjects get hold of the soil in a very few weeks, and do much better for being moved to their blooming pots early; for this final shift, let the soil be rich and light, using amongst it a good quantity of leaf mould, a material in which the roots of soft-wooded plants delight, and it may not be out of place to remind those who have not had much experience in plant-growing that the ability to produce an abundance of flowers with most pot plants, especially those of quick growth, in a great measure depends upon the amount of roots which they possess. Old plants of Fuchsias rested under greenhouse stages, or in similar out-of-the-way places, should not be allowed to become dust-dry, as in that case many of the roots perish. On the contrary give them a little water at intervals so as to prevent such an occurrence. They should now be pruned, cutting back the side shoots to within a couple of eyes of the main stem, and shortening the latter to about 18 inches above the pot; for, if left too high, the bottom of the plants do not get furnished with flowering shoots. It is always better to prune Fuchsias some time before they are started into growth than afterwards, as, if not so treated, they frequently bleed so much as to weaken them. Where any of these old plants are required in bloom early they should be at once placed in a light situation, but do not excite them by putting them into heat.

Vineries.—Vines should at once be pruned, an operation in which it is not advisable to be too much guided by mere appearances; gardeners experienced in Vine culture generally prune close, as when so managed the canes look best, but this is frequently carried too far, consistent with the certainty of obtaining good crops. Vines under the care of amateurs, seldom have their wood well ripened, especially after such a damp dull autumn as the last, and when this is the case, very close pruning is calculated to still further reduce the chances of a crop. Amateurs should not therefore prune too close, but should leave at least two eyes to each shoot after being cut back. Long spurs are certainly unsightly, and by thus treating the shoots, the spurs soon get a considerable length, but it is better to leave them long than endanger the crop; if, when the Vines break both eyes show bunches, that which is furthest from the spur can be rubbed off. It is usual after pruning to dress Vines with some mixture, calculated to destroy the eggs of red spider or thrips that may have infested them during the summer, for if seldom happens that red spider at least is altogether absent. To more effectually eradicate all traces of this pest, it is customary to strip off the old bark, a questionable practice; but no harm can result from removing any that is loose. To scrape off the whole covering, as is often done, is, however, unnatural, the baneful effects of which are evident from the fact that Vines subjected to such treatment never thicken out as they ought to do. The dressing just alluded to ought to be applied as soon as they are pruned; for, if delayed until the buds begin to swell, they sometimes get injured, especially if sulphur is used in considerable quantity. The safest mixture is clay and water well worked up to the consistency of thick paint; in this mix a little fresh cow-dung to make it stick, and to each gallon of the mixture add 1 pound of sulphur and a little soil, keeping the whole well stirred as it is used, otherwise the sulphur will settle to the bottom; for laying it on, an ordinary paint-brush may be employed, or the more customary substitute made of bast tied to a short stick may be resorted to. The chief point is to see that the mixture gets into every crevice, so as to cover the whole, from the surface of the soil to the extreme points. It is the more requisite to get every part of the young wood covered if thrips has been present during the preceding summer, as the eggs of this pest will be found on the young wood, sealed up under small, black, varnish-like

spots, under which they lie secure until brought to light by warmth. If there are inside borders, a couple of inches of the surface soil may be taken off and re-placed with fresh material. The wood-work should also be well scrubbed with soap and water, painted, if required, previously washing the glass and lime-washing the brick-work. The Vines, when dressed, may be tied lengthways across the front lights or lower part of the roof, where they can remain till the buds have broken. Early forcing is not to be recommended, except under experienced cultivators, as the chances of losing a crop, in the case of early-started Vines, are much greater than if they are pushed into growth later in the spring.

Peaches.—Where those are grown under glass they should at once be pruned, as if deferred later the buds will begin to swell, after which they are easily rubbed off. In pruning Peaches and Nectarines, judgment is required not only to leave the best-placed shoots for the present season's crop, but also such as will produce bearing wood to furnish the trees evenly for the following year. Do not leave the shoots too close, as anything approaching overcrowding is worse in its effects with trees under glass than in the case of those on open walls, where there is nothing to obstruct light. Wood-buds are easily distinguished from fruit-buds by their being so much smaller and more elongated. See that one of these thin buds is left at the point to which every shoot is cut back, for if they are absent there can be no growth made from the end of the shoot, the effect of which will be that the fruit upon it will not swell freely owing to there being no shoot to draw up the sap. When pruned, the trees should immediately receive their winter dressing, for which purpose Gisburst and similar compounds are often recommended; but, unless used by those who are experienced serious mischief is frequently the result, the bloom buds often falling off in quantities. Even if applied with the greatest care this will happen, if the dressing is too strong. A mixture, similar to that recommended for Vines, is much safer, and if applied so as to reach every crevice, will be found perfectly effectual. In laying it on, care must be taken to touch the buds very lightly or they will be injured. When this kind of work is finished let the trees be tied; in doing this the bast should in all cases be crossed between the wire and the shoots, so as to keep the latter from coming in contact with the iron; never let the ties be drawn tightly; on the contrary, leave enough room for the expansion of the shoots. Give the house a thorough cleaning, both woodwork and glass, so as to impart to the whole a neat, orderly appearance, and admit as much light as possible; scrape off an inch or two of the surface soil in the way already recommended, and re-place it with new loam and rotten manure. On no account allow Peach borders to get dry. Peaches are never quite at rest; even when without leaves the buds are slowly swelling, and if ever the soil gets too dry they are certain to suffer more or less, frequently resulting in large numbers falling off. Peaches and Nectarines, with their roots in inside borders, often suffer more through this cause than any other.

Conservatories.

Continue to wage war with all insect pests, such as thrips and scale. Half measures are of no avail with these; indeed, nothing but hand-washing or immersing the heads of plants infested with them in strong solutions of Fowler's or some other insecticide will rid them of these pests. Where it can be done, the latter is the quickest and surest way of destroying them, as with hand-washing some are almost sure to escape, and these soon re-stock the plants with their progeny. By taking the plants in hand at once, while they are at rest, they will stand a much stronger solution of insecticide than at any other time. In the case of thrips and scale, it requires from 4 to 6 ounces of insecticide to the gallon of water to make sure of its being effectual. White scale, the most troublesome of all insect pests, is sure to effect a lodgement on the old stems of Tacsonias, and if not cleared off, they soon make their way to the young leaves and branches. Where the stems of creepers are infested with these, they should at once be scrubbed with a tolerably hard scrubbing-brush, using, at the same time, any of the insecticides to work into the crevices. As the young wood of Tacsonias goes out of bloom, it may be gradually cut away, so as to induce them to break well back, and start afresh with increased vigour. Guard carefully against damp by removing any dead or decaying leaves or petals as they occur. Maintain a uniform temperature of 45° to 50°, which will be found quite warm enough to accommodate almost any flowering plant at this season, excepting the more tender stove varieties. Where Camellias have to be subjected to artificial heat, they should have a gentle bed-dew with clear soft water, so as to keep the leaves and buds moist, or the latter will be apt to fall off. Others expanding their bloom must be kept in a cool dry atmosphere, or the flowers quickly become discoloured. While swelling their buds, and carrying a crop of bloom, they must have

plentiful supplies of water, as the energies of the plants are then taxed to the utmost. Clarified soot-water, mixed with clear liquid manure, will be found of the greatest assistance during the period of blooming. Soot water imparts a luxuriant green tinge to the foliage, and is one of the safest and best fertilisers it is possible to employ. Weak solutions of guano-water, in the proportion of two table-spoonfuls to four gallons of water, have likewise a very beneficial effect, and they have the advantage over ordinary liquid manures of being usable without being offensive. With *Primulas*, *Cinerarias*, *Libonias*, *Eparcises*, *Heaths*, *Mignonette*, *Cyclamens*, *Schizostylis*, &c., there is no lack of bloom even at this dull season. Backs of greenhouse stages, or other similar places under glass, may be turned to good account in forwarding many of the deciduous plants intended for forcing. By placing them in positions of that kind they come on slowly, and require much less forcing than if left exposed to the weather. Such things as hardy *Azaleas*, *Wigolias*, *Lilacs*, and numerous other plants of that class, may even be helped forward in any close shed by keeping them well syringed.

Stove and Greenhouse Ferns.

In too many instances one house has to serve for both of these classes, and, where this is the case, neither can have the proper treatment they require, without in some way interfering with the health and well-being of the other. The stove varieties being of most value, and the first to suffer if the temperature of the house is unduly depressed to suit other kinds, should of necessity have the first consideration, and the treatment of the greenhouse kinds be made subordinate to these. Most of the former will winter safely in a temperature of 50° to 55°, with a slight rise during the day, and nothing is gained by having more heat than is absolutely necessary. In the case of some of the most tender, such as the *Gymnogrammas* and some of the *Notochlammas*, the lightest and warmest part of the house should be chosen to place them in during the winter months. By keeping them moderately dry at the root, so as to prevent flagging, and with the atmosphere as dry as is consistent with the safety and welfare of the other occupants of the house, they will be found to winter well, and start with more vigour in the spring than if subjected to a higher temperature. Where greenhouse kinds have to be grown in the same house they should be ranged at the coolest end, and be kept as dry as possible without allowing them to flag, so as to prevent them starting into growth. Peat and loam should at once be got under cover, that it may be kept dry and in good condition for potting purposes, as the time for this is at hand.—J. S. W. P.

Indoor Fruit Department.

Vines.—In many instances fruit will be set on the earliest started pot Vines, and where all the bunches that have appeared are still hanging, they should all be cut off except the best formed and set, six of which will be enough for a crop. It often happens that the finest bunches are produced close to the top of the cane, and if those lower down are indifferent, the bulk of the crop may be left on the top. The berries on the bunches left must be thinned as soon as they are the size of small Peas. Black Hamburgs must not be thinned so much as they require to be on established Vines, as in the case of pot Vines they seldom swell more than three-quarters their natural size. Royal Muscadine, Duchess of Buccleuch, and Grizzly and White Frontignans are naturally very small berried sorts, and great care must be taken not to over-thin them. As the bunches on these varieties are also small, strong Vines may be allowed to bear eight of them. After the thinning is over each shoot should be constantly pinched at two joints beyond the bunch. Shoots with no fruit on them may be restricted to four joints. Syringe every afternoon with tepid water, give the roots a little guano at every alternate watering and continue to do this until the fruit begins to ripen. The temperature may be kept at about 70° at night, and 75° throughout the day. Where Vineries are being started, high temperatures must be positively avoided, 55° at night and 60° during the day will be quite heat enough, the exception being 5° more with sun heat, or 5° less on extremely cold nights. A good bed of leaves and litter should be placed on the inside border and see that cold is excluded from that on the outside. Continue to stop and tie the shoots of permanent Vines, and when they come into bloom cease syringing. The atmosphere, too, should then be kept comparatively dry, and cold draughts must be guarded against.

Pines.—Queens lately placed in a forcing temperature will now be starting into growth, and should be liberally supplied with water at the root. Where the pots have been loosened to permit excessive bottom-heat to escape, replace the plunging material firmly about them, when the heat has subsided to 80°. The atmospheric temperatures may now be increased 5°; keep succession Queens at rest and look over suckers in small pots in order to see that the roots are not suffering from want of water. If the plunging material is very dry,

as it is apt to become under constant firing, give it a good watering so as to keep it in a fresh healthy state.—J. MUIR.

Kitchen Garden.

The kitchen garden must, of necessity, ever stand at the head of all the departments of gardening; not because it requires more skill in its management, but because so much is expected from it, and that daily throughout the year. The allowances generally so freely made for the fickleness of fruit crops through bad weather, do not extend to the vegetable department from which supplies must at all times, and under all circumstances, be forthcoming. Hence the reason I attach to it so much importance, and I would urge on young gardeners, especially if they wish to succeed, the desirability of thoroughly mastering this branch of gardening. I am sorry, however, to say that I have occasionally met with young men who have had the greatest contempt for kitchen gardening. To young men of this description, my notes will be of little service, but to those who, like myself, are especially interested in kitchen gardening, the hints which I shall give from week to week during the coming year, will, I hope, prove of value; first, as reminders of work to be done, and secondly, as to how and when to do it. The continuous rains which we have had throughout the autumn and early winter months having prevented the performance of trenching, digging, and draining operations, on every fine day now such work should be advanced a step, in order that the ground may have the full advantage of the action of frost upon it, such action being especially desirable on heavy, retentive soils. On frosty mornings, when the ground is firm and dry, manure should be wheeled on to vacant plots ready to be dug or trenched in on the disappearance of frost. Clear the dead stems off *Asparagus* plantations, and cover them thickly with rotten manure; afterwards give them a liberal dressing of coarse salt, to be washed in by the rain. I do not approve of the ordinary way of growing this vegetable, viz., in 4 feet beds, with a deep alley between them, half the roots being naked. I prefer to plant on the level ground, in rows 2 feet apart, dressing and manuring them annually, as has just been named. Sow a few Broad Beans on a ridge or warm border, Early Dwarf Cluster and Early Long Pod being the best kinds for the purpose. Also, sow a few rows of Peas, such as Ringleader and William the First. The last-named variety is a wrinkled Marrow, as early as Ringleader, and more productive. Any Peas that are up should have some soil drawn to them, as a protection from cutting winds, frost, and vermin. Birds (sparrows in particular) are very fond of pinching out the points of the young shoots as soon as they are through the ground. A good deterrent, and also a valuable fertiliser, is an occasional sprinkling of soot over the rows. Brussels Sprouts, a vegetable in use all through the dead of winter, require a very long season if wanted to be extra fine; they are, therefore, best sown in autumn, and left in the seed beds till spring. If not sown then, however, sow at once, in drills, 9 inches apart; cover the seed very slightly, and protect it with netting from birds. Imported seed is the best, because it grows the tallest, and consequently produces the largest number of Sprouts. Cauliflower plants under hand-lights, cloches, or in frames, should be fully exposed whenever the weather is favourable. These are generally kept too close, the impression being that such treatment will cause them to head early; but that is a mistake, as they will come in no sooner, and are much more liable to "button" than when brought up sturdier. We have yet a few heads of that best of all Cauliflowers, Veitch's Autumn Giant, a kind which has furnished a supply of good Cauliflowers till Snow's Broccoli came in. From the latter, we have been cutting for some time, and others are ready to be taken up and put in sheds or frames on the first appearance of severe weather. Early kinds of Potatoes may now be started to sprout in warmth. Lay them in shallow boxes filled with sifted leaf-mould, and give them occasional sprinklings with a fine rosed water-pot or syringe. As soon as sprouted and well rooted, pull off all the shoots except two, and plant them deeply on warm borders that can be readily protected if required. Start and treat them in a similar manner, for planting in pits, frames, or pots. Our first supply is always from pots, and it generally turns out satisfactorily. Three tubers are planted deeply in a 8-sized pot, and are earthed up as the haulm progresses; the temperature of a newly-started Vinery or Peach house suits them well, and they can be easily moved to other quarters when desired. Have the necessary protection ready for Celery, Lettuce, Endive, and Parsley, in case of severe frost; straw hurdles are the neatest, handiest, and most effectual protectors that can be employed for such purposes. Keep up successional supplies of *Asparagus* by making up a fresh bed about every three weeks. In bad weather look over stores of Beet, Potatoes, Onions, Jerusalem Artichokes, and Carrots, removing every trace of decay, as one bad root soon infests a large number.—W. WILDSMITH, *Heckfield*.

PLATE I.

THE GREAT ST. BRUNO'S LILY.

Drawn by F. W. BURBIDGE.

THIS is a noble variety of a very beautiful alpine flower. It is as pure in colour as the White Wood Lily of the North American woods (*Trillium grandiflorum*), and is unlike the common alpine form, tall and stately as a true Lily, with long and elegant grassy leaves, and a delicate and welcome odour. We have not seen this large form in a wild state, if, indeed, it so exists. When the early summer traveller first crawls down from the cold and snowy pass of a Savoy Alp into the grateful warmth and English-meadow-like freshness of the valley, most likely the first flower he notices in the fresh Grass on the side of the valley is a small Lily-like blossom, standing about level with the tops of the blades of Grass and the Orchises. The blooms, about 2 inches long, so clearly and delicately white that they might well pass for emblems of purity, have each division faintly tipped with pale green. One or perhaps two stems spring up here and there all over the meadows, and the effect of the half-pendent Lilies is very beautiful. The description and synonyms given of this plant in "Curtis's Magazine" are the text for a good deal of amusing comments on botanical nomenclature and its difficulties in the first number of Mr. Ruskin's "Proserpina." His favourite, however, seems to be the branched *Anthericum Liliago*, which is by no means so fair a flower as the single-stemmed and true St. Bruno's Lily. The variety now figured I saw for the first time last summer in Messrs. E. G. Henderson's nursery, at St. John's Wood, and from the specimens then gathered and brought to THE GARDEN office Mr. Burbidge made the sketch of which our plate is a reproduction. It speaks for itself. The plant will be found to be one of easy culture on warm free soils. Slight shelter would prove beneficial, and that may readily be obtained by planting it among rather dwarf shrubs. It is valuable for the mixed border, and, when plentiful enough, would prove worthy of naturalisation in open spots in semi-wild places where the soil is good. It may be most readily increased both by division and seeds, but is as yet scarce in nurseries. W. R.

THE LIBRARY.

"GARDENING FOR PLEASURE."*

THIS is a handy little book, and one for which we have a hearty welcome, for it is rarely that we find so much sound and practical advice given so plainly, or contained in so small a compass. Extending through 250 well-printed pages, and amply illustrated throughout, we have ably written and exhaustive little essays on soil and locality, drainage, manures, lawns, designs for gardens (which, by-the-by, are not first-rate, and convey no new ideas to the intelligent reader), bulbs, propagation by seeds and cuttings, grafting and budding, tropical bulbs and seeds, potting plants, winter flowering plants, remedies for unhealthy plants, hanging baskets, and window gardening. We have also chapters on the cultivation of plants in rooms, warden cases and Fern shades, how to force certain plants, greenhouses, Graperies, heating by hot water, cold houses and pits, combined cellar and greenhouse, hot-beds, insects, and diseases, besides many other suggestively-written pages on the fruit and vegetable garden, with excellent selections of the best and most profitable kinds to grow. The chapters on fruits and vegetables are well illustrated, as is also the essay devoted to garden implements, while the whole book is aptly concluded by a most excellent monthly calendar of operations. As a matter of course, this book is written for American readers, and the selections are made with a view to suit a climate which differs in many important points from ours; notwithstanding this, however, it would be useful to many English cultivators. To such we can confidently recommend it as being generally a straightforward little book from the hand of a thoroughly practical horticulturist. We here give Mr.

Henderson's remarks on mulching and shading, which will convey to the amateur some idea of the practical and suggestive contents of this work:

Mulching.—Litter of any kind, placed around newly planted trees to prevent evaporation from the soil, was the original meaning of mulch, but it is at present extended to include a covering of the soil applied at any time, and for very different purposes. Good cultivators apply hay, straw, or other litter to the surface of the soil to protect the roots of certain plants against the action of frost, it being useful, not so much against freezing as to prevent the alternate freezing and thawing, that is apt to occur in our variable and uncertain climate, even in mid-winter. As mentioned under Strawberry culture, the mulch applied in the fall protects the roots during winter; it is allowed to remain on the bed where, if thick enough, it keeps down weeds, and prevents the evaporation of moisture from the soil during the dry time we are apt to have between the flowering and the ripening of the Strawberry. Besides all this, it makes a clean bed for the fruit to rest upon, and should a driving shower come up as the fruit is ripening, there is no danger that the berries will be splashed with mud and spoiled. The utility of a mulch is not confined to the Strawberry among fruits; Raspberries and Currants are much benefited by it, and by its use a gardener of my acquaintance succeeds in growing fine crops of the fine varieties of English Gooseberries, a fruit with which very few succeed in our hot summers. Newly planted trees, whether of fruit or ornamental kinds, are much benefited by a mulch, and its application often settles the question of success or failure. We have known a whole Pear orchard to be mulched, and the owner thought its cost was more than repaid by saving the fallen fruit from bruises. The rooting of a layer is by some gardeners thought to be facilitated by placing a flat stone over the buried branch; the fact being that the stone acts as a mulch, and prevents the soil around the cut portion from drying out, and greatly favours the rooting process. Even in the vegetable garden, mulching is found useful, especially with Cauliflowers, which find our summers quite too dry. The material of the mulch is not of much importance, the effect being purely mechanical, one kind of litter will answer as well as another; the material will be governed in great measure by locality; those living near salt water will find salt-hay, as hay from the marshes is called, the most readily procured; those who live near Pine forests use the fallen leaves, or Pine needles as they are called; in the grain-growing districts straw is abundant, and nothing can be better; it can be applied more thoroughly if run through a cutter, though the thrashing-machine often makes it short enough. Leaves are Nature's own mulch, and answer admirably; if there is danger of their being blown away, brushwood laid over them, or even a little earth sprinkled on them will keep them in place. Tan-bark and sawdust may serve for some uses, but they are very bad for Strawberries, their finer particles being about as objectionable as the soil. One of the best materials to use for summer mulching is the green Grass mowed from lawns. This applied, to the thickness of 2 or 3 inches, around the roots of all kinds of small fruits, will be found not only to greatly benefit the crop, particularly in dry weather, but will save greatly in labour by preventing the growth of weeds. One of our best private gardeners in the vicinity of New York has adopted this summer mulching with the Grass from the lawn for nearly twenty years, and has succeeded in growing all kinds of small fruits in the highest degree of perfection.

Shading.—In mulching the object is to prevent evaporation from the soil, as well as to shield the roots from sudden changes of temperature; it is often necessary to protect the whole plant in this respect, and this is accomplished by shading. Although on a large scale, we can do little in the way of shading plants in the open ground, yet the amateur will often find it of great utility, as screening will frequently save a recently transplanted plant, which without it would be quite ruined by a few hours' exposure to the sun. For shading small plants in the border, such as transplanted annuals, a few shingles will be found very useful, one or two of these can be stuck in the ground so as to completely protect the delicate plant, and yet not deprive it of air. Six-inch boards of half-inch stuff nailed together, to form a V-shaped trough, are very useful in the garden; they are handy to place over small plants during cold nights, and may be turned over and set to make a screen against strong winds, or used for shading plants in rows. Seedlings often suffer from the heat of the sun in the middle of the day; the seedlings of even the hardiest forest trees are very delicate when young. The seeds of such trees when sown naturally almost always fall where the young plant will be shaded, and the amateur who experiments in this very interesting branch of horticulture, the raising of evergreen and deciduous trees and shrubs from seed, will find it necessary to imitate Nature and protect his young seedlings from the intense heat of the sun. There are several

* "Gardening for Pleasure. A Guide to the Amateur in the Fruit, Vegetable, and Flower Garden," &c. By Peter Henderson, New York: Orange Judd Company, 1875.

ways of doing this; if the seeds have been sown in an open border, let him take twigs about a foot long, evergreen if they can be had, but, if not, those from any deciduous tree, and stick them a few inches apart all over the bed. This will give the seedlings very much such a protection as they would naturally have had in the shade of other plants, and though evergreens will look better for a while, the dead leaves of deciduous twigs will give quite as useful a shade. It is always safer to grow seeds in a frame, as the young plants are then under more complete control. Frames are easily shaded by means of a lattice made of common laths. Strips of inch stuff, $1\frac{1}{2}$ or 2 inches wide, are used for the sides of the lattice, and laths are nailed across as far apart as their own width. One lath being nailed on, another is laid on to mark the distance, the third one put down and nailed, and the second one is moved along to mark the distance for the fourth, and so on. With a screen of this kind there is abundant light, but the sun does not shine long at a time on one spot, and the plants have a constantly changing sun and shade. This lath screen may be used for shading plants in the open ground if supported at a proper height above them. In a propagating-house, where it is necessary, as it often is, to shade cuttings, a lattice laid upon the outside of the glass answers a good purpose. The laths are sometimes tied together with strong twine, the cord answering the place of slats, and serving as a warp with which the laths are woven; the advantage of a screen of this kind is that it can be rolled up. Plants kept in windows during the summer months will, if in a sunny exposure, require some kind of a shade, and if the one provided to keep the sun from the room shuts out too much light, or excludes air as well as sun, something must be provided which will give protection during the heat of the day, and still allow sufficient light and an abundant circulation of air. Anyone with ingenuity can arrange a screen of white cotton cloth to answer the purpose. The old practice of stripping the greenhouse in summer is falling into disuse, and by a proper selection of plants and sufficient shade, it is made as attractive then as at any other season, but even for tropical plants the glass must be shaded. For a small lean-to, a screen of light canvas or muslin arranged upon the outside, so that it may be wound up on a roller when not wanted will answer, and if it be desired to keep the house as cool as possible, this should be so contrived that there will be a space of 6 inches or so between that and the glass. But upon a large house, or one with a curvilinear roof, this is not so manageable, and the usual method is to coat the glass with some material which will obstruct a part of the light. The most common method is to give the outside of the glass a coat of ordinary lime whitewash; this makes a sufficient shade, and is gradually dissolved by the rains, so that by autumn the coating is removed, or so nearly so that what remains may be readily washed off. A more pleasant effect is produced by spattering the glass with the same wash, which can be done by a dexterous use of the brush, and stippling it so as to leave the wash in numerous fine drops, like rain-drops. Others use whitening and milk for the same purpose. Whatever may be the means of effecting it, we find that in this latitude shading of some kind is required from about the 1st of May to the middle of September, by nearly all plants grown under glass. Ferns, Lycopods, Caladiums, Primulas, Fuchsias, Begonias, Gloxinias, Achimenes, Lobelias, Smilax, and plants of that character require the glass to be heavily shaded, while Roses, Carnations, Bouvardias, Poinsettias, Geraniums of all kinds, and nearly all succulent plants, do not need so much. The method of spattering the glass outside with thin whitewash, allows the shading to be light or heavy, as required. When first done, it is spattered very thinly, merely to break the strong glare of the sun, just about thick enough to half cover the surface. As the season advances, the spattering should be repeated, to increase the shade, but at no time for the plants last-mentioned do we entirely cover the glass. In England, especially for Fern-houses, Brunswick green mixed with milk is used, to give a green shade, which is thought to be best suited to these plants. The blue glass for greenhouses which was so highly lauded a few years ago, has not met with much favour; but recent experiments in glazing with ground glass, have given such results as to warrant a more careful investigation into the use of this material.

PAINTING GLASS-HOUSES.

WHITE lead, mixed with linseed oil, is the best paint for the wood-work of glass-houses. The wood should be thoroughly dry throughout when it is put on, for internal damp soon works out, and blisters and destroys the paint. The long dry period in summer is the best time to put it on, but the wood of new houses being erected now, should be well painted over once before it is brought out of the workshop, and other coats should be applied as the weather will permit. To let the wet penetrate the wood before it is painted is a sure means

of starting decay, which no after attention will remedy. Few houses are improved in appearance by being painted in a great many colours. Two are generally sufficient, and these should consist of a stone colour on the wood, and some shade of blue on the iron. The most effectively painted house I have seen lately, is a very large new one, in which the colours are a very light lemon and a French grey, the former being put on the wood, and the latter on the iron. Blue is a colour much used on iron, and sometimes along the lower edges of the rafters; it and a pearl-white look well together, but the latter should only be used in conservatories and other places where the atmosphere is quite clear. In stoves, forcing pits, and similar structures, the wood-work should be painted a dark stone colour, as the filth which soon gathers about the lower parts of these houses, is not so easily seen on this shade as on a lighter one. For the same reason the outsides of all houses should be of a dark hue; near towns, stoveholes, or chimneys, the smoke soon makes the paint very black, but further than looking dirty this does no harm. The outside generally requires painting oftener than the inside. With ordinary usage the inside need not be painted oftener than every six years, whilst the outside in most cases needs re-coating every third year. Nothing is to be gained by letting the wood become bare of paint; in fact, avoiding this is the only way to make the wood last. In old-fashioned houses where the principal supports are veritable logs of timber, it is perhaps not so rapidly followed with decay and downfall, but the durability and preservation of light framed wooden structures, can only be ensured by keep them constantly well painted.

J. MUIR.

VITALITY OF SEEDS.

ALTHOUGH there is no doubt that the seeds of many plants retain their vegetative powers for a long period under certain conditions, absolute proof is still wanting to confirm the supposed germination of grains of Wheat, &c., taken from Egyptian mummy-cases and other sources. Carefully-conducted experiments by scientific men of different countries have furnished little beyond negative results. We ourselves have tried in vain to raise various seeds, ranging from fifteen to twenty-five years old, which had been more or less exposed to atmospheric influences—that is to say, they were kept in paper bags. Buried in the soil to a certain depth, it seems quite possible that some seeds would retain their vitality for an indefinite number of years. This is so far true that in some districts where the arable land has been very much infested with the Charlock, and the farmer has succeeded in nearly exterminating it, he is very careful not to plough deeper than usual, which invariably brings a quantity of fresh seed within germinating distance of the surface of the soil, and is the cause of weed increasing and spreading again with renewed vigour. Having similar facts in view, Dr. H. Hoffmann has been experimenting with soil taken from the diluvial beds of the Rhine districts. We should mention, too, that he hoped to obtain some interesting results affecting the transmutation theory, and some explanation of the peculiar distribution of certain plants found in the Middle Rhine district. The results he has published in the "Botanische Zeitung" (Nos. 42 and 43, 1875). For the purposes of the experiments, about three-quarters of a hundredweight of the Loss soil was taken out at a depth of 12 feet below the surface, when the earth was being levelled for the railway station at Monsheim, near Worms. A newly-broken spot was selected, and the tools previously cleaned with well-water. In fact, every conceivable precaution was taken throughout the experiment to prevent the intrusion of foreign seeds or spores. Notwithstanding all this care, various common Mosses, Ferns, and flowering plants sprang up in the pots, which were closely covered with bell-glasses. It is noteworthy, too, that all the species that sprang up in this way were common either in the greenhouse or its immediate vicinity, and not in the locality whence the soil was procured. A similar set of experiments was instituted with white tertiary sand, and the result was the same. And the experiment with Loss soil was repeated again. In this instance the only plant that could possibly have sprung from a seed in the long buried soil was *Festuca pratensis*, but this was a delicate plant, probably from a very small light seed, that might have been conveyed by the air. It will thus be seen that all these experiments gave results of a negative character. But the author has put them on record, and wisely, we think, to show the difficulties in the way of obtaining satisfactory proof in experiments of this nature. Altogether they go to strengthen the view that "Egyptian mummy Wheat" was accidentally introduced with the actual grain taken from the cases.—"Academy."

Early Mention of Guano.—The earliest mention of guano is said to be by Ulloa in his work on Peru, published after his return from that country in 1745. The next known mention of it is by Humboldt. You may be interested, therefore, in publishing the following extract from a

Little book which I accidentally "picked up" a few days ago. The mention of guano in it is probably the earliest use of the word in any book in the English language. The title of the book is, "The Art of Metals, &c., in Two Books, written in Spanish by Albaro Alonso Barba, Master of Art, Curator of St. Bernard's Parish, in the Imperial City of Potosi, in the Kingdom of Peru, in the West Indies, in the year 1610. Translated in the year 1669. By the R. H. Ely, Esq. Earl of Sandwich. London: Printed for S. Mearme, Stationer to the King's Most Excellent Majesty, 1674." The extract is from pp. 6, 7—"Out of islands in the South Sea, not far from the City of Arica, they fetch earth that does the same effect as the last afore-mentioned (Britannica). It is called guano (i.e. dung), not because it is the dung of sea-fowls (as many would have it understood), but because of its admirable vertue in making ploughed ground fertile. It is light and spongy, and that which is brought from the island of Iqueyque is of a dark grey colour, like unto tobacco ground small. Although from other islands near Arica they get a white earth inclining to a sallow, of the same vertue. It is constantly carried water whereunto it is put, as if it were the best leigh, and smells very strong. The qualities of vertues of this, and of many other simples of the new world, are a large field for ingenious persons to discourse philosophically upon, when they shall bend their minds more to the searching out of fruits than riches." I may mention that Ulloa was captured by us on his voyage home from Peru, but, on his arrival in England was at once liberated and made a F. R. S.—"Athensum."

THE FRUIT GARDEN.

DECEMBER PEARS.

This following is a condensed list of the choicest December pears, which, together with the October and November lists, will make up a thorough, and I think, reliable catalogue of autumn and winter Pears, at least so far as the three months mentioned go. If the most select are required, they may I think with confidence rely upon those marked with an asterisk. I have been engaged in the arduous task of collecting, cultivating, and proving all, or nearly all the sorts I could procure, and my collection contains many new kinds, which it will take some time yet to test properly, and so could not be included in these lists. It is my intention however, during the winter and early spring, to give you all the information I possess at present about them. The sizes, as in the former lists, are indicated by 1st, 2nd, and 3rd.

- Abbé Pérez—2nd, flesh melting, very juicy, and delicately perfumed.
Adèle de St. Denis—1st, flesh melting and buttery, juicy excessive, sugary, and well flavoured.
Agathe de Lescault—2nd, melting, sugary, and aromatic.
Alexandre Lambré—described in November list, but good also for December.
*Althorp Grassane—2nd, very juicy, sugary, and highly perfumed.
Amand Bivort—1st, very melting, juicy, and exceedingly savoury.
Amand Bivort—2nd, melting, juicy excessive, rich, and sugary.
Angélique de Rome—1st, melting, sugary, with a fine delicate aromatic perfume.
" Leclerc—1st, melting, sugary, with a fine delicate aromatic perfume.
*Baron Deman de Lennick—2nd to 3rd, juicy excessive, and delicately perfumed.
" Inglemaunster—2nd, very juicy, rich, and delicate.
Belle et Bonne de la Pierre—2nd, flesh sweet scented, sugary, and delicate.
" Du Figuier—1st, flesh very melting, juicy excessive, and savoury.
" Fleurissienne—2nd, half-melting, sugary, vinous, and aromatic.
*Bergamotte Espere—2nd to 1st, very melting, very juicy, and delicious. This is, if not the best, at least one of the best winter Pears.
Bézi d'Espere is often sold for it, but it does not keep so long.
" March—2nd, melting, juicy, and good; very like Monarch in all its bearings, and has a family resemblance to most of Mr. Knight's other Pears, i.e. Broom Park, Althorp Grassane, Shobden Court, &c.: all good winter kinds.
" Sageret—1st to 2nd, melting, delicate, with a savoury perfume.
*Bernard—2nd, very melting, very juicy, delicate, and very savoury.
Bési Incomparable—2nd melting, juicy, and very aromatic.
*Beurré Bachelier—1st, melting, juicy excessive, sugary, delicate, and perfumed.
" Beaumé—2nd, melting and fine, juicy excessive, sugary delicate, and perfumed.
" Berckmaus—1st, very melting, juicy excessive, refreshing, and delicate.
" Défay—1st, melting, very juicy, sugary, vinous, and delicate.
" Fideline—2nd, melting, juicy, sugary, and delicious.
" de Ghelein—1st, melting, juicy excessive, and agreeably perfumed.
" *Gris d'Hiver Nouveau—2nd, melting, very juicy, aromatic, and delicious.
" Millet—1st, melting, very juicy, sugary, and highly perfumed.
" Nivelles—1st, half-melting, very juicy, sugary, and richly perfumed.
" Philippe Delfosse—1st, very melting, juicy excessive, sugary, highly perfumed and delicate.
" *Rance—1st, when grown against a wall, which it should always be, it is then unsurpassed as a Christmas Pear.
" St. Marc—2nd, flesh close, melting, excessively juicy, with a fine aroma.
" Samoyeau—3rd, melting, juicy, with a good Beurré flavour.
" Six—1st, one of the best of Pears from October to January.
" Wetteren—2nd, very melting, sugary, and highly perfumed.
*Ronne de Malines—2nd, juicy excessive, flesh melting and perfumed.
*Bonnesseur de St. Denis—1st to 2nd, melting, juicy, sugary, and well perfumed.
Brandès—3rd, very melting, sugary, and with a savoury perfume.
Brindamour—2nd, juicy excessive, flesh melting, sugary, and richly perfumed.
Broom Park—2nd, half-melting, very juicy, sugary, and refreshing; very like Shobden Court, and of much the same quality.
*Cadet de Vaux—1st, melting, juicy excessive, rich, and sugary, continues from December to March, and sometimes to May.
Clement Bivort—2nd, flesh fine, melting, juicy, rich, and sugary.

- Colmar—1st, flesh half-melting, juicy abundant, and very sweet; requires a wall to bring it to perfection.
" *Dahault—2nd, very juicy, half-melting, rich, and aromatic.
" *Comte de Flandres—2nd, very melting, rich, aromatic, and exquisite.
" Comtesse d'Aloust—1st to 2nd, flesh close and very melting, juicy excessive, and savoury.
" *d'Chambord—flesh melting, refreshing and delicate.
" *Doyenné d'Alençon—2nd, very melting, very juicy, sugary, and aromatic.
" do Rouen—2nd, very melting, juicy abundant and delicate.
" *Siculle—2nd, flesh fine, half-melting, juicy, sugary, and delicate.
" *Duchesse de Bordeaux—1st, melting, very juicy, refreshing, and delicate.
Emilie Bivort—2nd, very melting, delicious, and perfumed.
" *Figure d'Alençon—1st to 2nd, juicy, buttery, and highly flavoured; very good. This delicious Pear requires a warm soil to bring it to perfection.
" *Graslin—1st to 2nd, very melting, juicy excessive, sugary, delicate, and perfumed. Mr. Decaux says that this and Beurré Superin are the same; but they are entirely different—one ripe in October, the other in December.
Henriette Bivort—2nd, flesh breaking, very juicy, sugary, and acidulated.
" *Josephine de Malines—2nd to 3rd, very melting; and delicious; a valuable Pear.
" *Monarch—2nd and 3rd, one of our most valuable winter Pears.
Louis Vilmorin—1st, flesh fine, melting, very juicy, sugary, and with a fine perfume.
Maréchal Vaillant—1st, very large, flesh half-melting, juicy, sugary, and perfumed.
Marie Bonois—2nd, melting, juicy excessive, sugary, vinous, and delicately perfumed.
" *Jalais—2nd, melting, very juicy, and delicious.
" *Marianne de Millespieds—1st, flesh very fine and melting, juicy excessive, sugary, acidulated, and exquisitely flavoured; in eating from December to April, a valuable winter Pear.
Orange d'Hiver—2nd, flesh half melting, and very delicious here; in some localities too astringent.
Passe Colmar—1st to 2nd, melting, juicy abundant, rich, and sugary.
Petite Victoire—3rd, melting, juicy, sugary, and acidulated.
" *Royal Vendée—2nd, flesh very fine and very melting, juicy abundant, and very agreeable.
" *Sabine—1st, flesh very melting, juicy, sugary, and very savoury.
St. Germain—1st, flesh firm and melting, juicy, sugary, and perfumed.
Sarasin—2nd, flesh breaking, very juicy, sugary, and acidulated.
" *Suprême Coloma—1st; described in November, but it is also delicious in December.
Vanquelin—1st, flesh firm and very melting, juicy very abundant, rich, and agreeable.
Verdusson—3rd to 2nd, flesh very fine and melting, juicy excessive, aromatic, and delicate.
Williams d'Orléans—1st, this fine new Pear should be grown on an east or west wall, to bring out all its good qualities.
" *Zéphir Louis—2nd, melting, juicy, sugary, perfumed, and savoury.

The above are all the best December Pears. There are not so many of them as of the two preceding months, but more of them are marked with an asterisk. I have always deemed the late autumn and winter Pears to be the most delicious; they are richer and more aromatic than the early kinds, which have often nothing to recommend them but their juiciness and sweetness, although there are a good many exceptions. The shelves of my fruit room are beginning to look bare, and there are now, on them, only about eighty sorts to be examined and several of these are cooking varieties. January, February and March will nearly exhaust the whole, as the sorts which last beyond March are few and far between. J. SCOTT.

OLD AND NEW APPLE ORCHARDS.

The enquiry is often made—" Shall I continue my old Apple orchard, of which some of the kinds are dying, or cut the trees down and plant new ones? And shall I plant on the same ground?" We answer—keep the old orchard as long as you can get anything from it. Do not plant on the same land; but while you keep the old trees in good condition as long as practicable, have a young orchard coming on in another place. If you cut down your old trees and plant a young orchard, you will be without fruit for several years. Old orchards, well managed, will grow and bear good fruit for some twenty years, longer than if entirely neglected. Apples are usually good for sixty years, and under favourable influences will often last for seventy or eighty. We have seen a tree known to be about 100 years old, but this was an exception. The oldest thrifty and bearing trees we have known, stood on the borders of gardens, where at least half the roots were in a cultivated and constantly enriched soil. Those standing neglected in Grass and weeds, at the same age, were declining, the limbs dying, and some had gone to decay. For an old orchard standing in Grass, we would not recommend unconditionally ploughing up the sod. A portion of the roots is necessarily cut or torn more or less by the plough; and while such a root-pruning (performed, of course, while the trees are dormant), may do no harm at all to a young and thrifty orchard, it might tend to check the growth of old trees, unless the mellowing of the surface might counterbalance the effect. It is safer therefore to top-dress the ground where old or decaying trees stand, with manure in autumn or winter, and to keep the Grass grazed short in summer with sheep, these animals also destroying the colling moth in the fallen fruit. Cut out all the dead limbs at the same time, and reduce the amount of the top by thinning out evenly the small shoots or branches. By thus reducing the number of shoots, those that remain will make a vigorous growth, and bear as good

fruit as younger trees. We have known some which had already lost a part of their branches by old age, restored to vigour and a moderate degree of productiveness, by stimulating the roots and thinning the top. It is important, however, to continue annually the care they receive, or they will soon fall back again. All this care is not great, and is well repaid by the crops which the old trees will continue to afford while the young trees are coming forward into bearing. When it is not practicable to obtain large supplies of manure for top-dressing, it may be best to break up the Grass sod under the trees by a shallow ploughing or digging early in spring before the buds swell; and by keeping the surface clean and mellow through the summer, a small application of manure broadcast will afford important assistance. A dressing of ashes, leached or unleached, if not more than fifty bushels per acre, will be useful to most soils. If the soil in which the trees stand is deep, and the roots extend downward several feet, the digging may be done without fear of injury. If, on the contrary, the sod happens to be quite shallow, and nearly all the roots are near the surface, greater caution must be used with old trees, although with younger orchards the small amount of mulch which the roots thus receive is overbalanced by the benefit of the cultivation.—“Cultivator.”

Twin Pine-apples.—The annexed is a representation of a twin Pine, drawn by the late Lady Boyno. It was grown at Brancepeth

Castle, and each of the fruits weighed nearly 4 lbs.; the kind is the Welbeck Seedling.—J. HUNTER, *Lambton Castle, Durham.*

Josephine de Malines Pear.—With us this is one of the most satisfactory of winter Pears grown; although not so large as many Pears that ripen at the same time, its excellent quality fully compensates for lack of size. With us it usually produces more bloom buds on the young wood than any other variety, and commences to bear freely at an earlier age than many varieties. It succeeds well as an espalier, but deserves a wall. The great number of varieties of Pears now in cultivation, renders it a matter of some difficulty for those with limited space, to select from even the best arranged catalogues.—J. GROOM.

New Varieties of Fruit.—At the recent International Exhibition at Ghent [England] was first with hothouse Grapes, and France obtained first honours for other kinds of fruit. M.M. Baltet, pomologists at Troyes, obtained for their collection three prizes given for the most numerous, the most interesting, and newest fruits. The following are amongst the least known and the most valuable:—Peaches (late)—Lord Palmerston, Lady Palmerston, Salwey, Smock Freestone, Baltet, Teindou, Princess of Wales, Stamp the World, Troyes, De Bozlen, and Belle de Toulouse. Nectarines—Albert, Lannois, and Pine-apple. Plums—Bryanstone Gate, Coe's Violette, Verdache, Jaune Tardive, Violette Galopin, Madame Nicolle, Mirabelle Tardive, Reine Claude de Wazon, Reine Claude d'Altham, and Tardive Musquée. The last-mentioned, raised by M.M. Baltet, has been

certificated by the Pomological Congress at Ghent. Pears—Alexandrine Mas, Antoine Delfosse, Auguste Mignard, Belle de Bolbec, Bergamotte Philippot, Bzi Incomparable, Beurré Baltet Père, Beurré Blondel, Beurré Ladé, Beurré Lebrun, Beurré Rouge, Brindamour, Comte Lelieur, Doyenné Boissard, Duchesse d'Angoulême Bronzée, Fondante Thirriot, Fortunée Boisset, Goodale, Hébé, Grosse d'Avril, Lucie Andusson, Madame Hutin, Madame André Leroy, Madame Lorial de Baruy, Madamo Grégoire, Marie Benoist, Olivier de Serris, Passe Crassane, Président Mas, British Queen, Bon Chrétien Prévoist, Souvenir de Leopold I., Souvenir du Congrès, Sucre de Montlucon, Vice-Président Delchaye, Royale Vendée, and Ellis. Apples—Amélie, Belle des Buits, Belle et Bonne de Huy, De Citron, De Soie, Du Lait, Du St. Sepulchre, De Wyden, Du Vigne, Fraisé de Hoffinger, Joséphine Kreuter, Prince Lippe, Reinette d'Étlin, Reinette Titus, Reinette Grammont, Souvenir de Botzen, Rouleau Rouge, Pousson de France, the superb Transparente de Croncles (certificated by the Congress), and the Menagère, which measured over 6 inches in diameter.—C. BALLET.

Fruit-preserving in the Open Air.—Under this title the “*Moniteur Horticole Belge*” describes a simple and inexpensive process of keeping Apples, taken from the “*Maison Rustique*.” Choose a dry place naturally protected by trees, evergreens preferred; and then place the fruit in a conical heap and cover it with leaves in the proportion of twice the bulk of the leaves to one of fruit. Under these conditions the Apples in contact with the soil receive a moderate and uniform heat; the leaves keep out the cold and water, and are maintained in their place by the trees, which protect them from winds. Fruits preserved in this manner are in better condition in spring, and decidedly more fresh than those wintered in ordinary fruit-houses. It is not rare for those who dwell in the country, to find Pears or Apples concealed under leaves very well preserved, better even than others with which great care has been taken; besides, this plan comprises the essentials for keeping fruits, the most important of which is protection against atmospheric variations. Again, not only are they better preserved, but they are more fresh and firm, which is due to the almost complete absence of evaporation, and hence their tissues are swelled out full, like freshly-gathered fruit. The economy of this plan is another important consideration. It is well worth trying, with a view of prolonging the season of some of the most useful keeping sorts.

Raspberries and Blackberries from Root Cuttings.—Mr. Fuller's directions for carrying out this plan are as follows:—Dig up the plants to be propagated late in autumn, with all the roots that can be secured. Cut the roots into pieces about 2 inches long, and place them in alternate layers with sand or fine Moss in a box. Place the box in a cool cellar to prevent growth; keep the sand or Moss moderately damp. Early in spring the cuttings will have well-developed buds. Plant them out in drills in rich ground 2 inches deep. If well cultivated they will make good plants by autumn.

Evidence as to Mulching Strawberries.—Mr. A. M. Purdy gives a successful instance of mulching in the “*Fruit Recorder*.” A grower, becoming tired of keeping his Strawberries clean, covered the whole plantation with straw early in autumn so as to hide all the plants. In spring they grew up through the straw and sent up a dense profusion of fruit stems. The season was very dry from May to July, but he obtained a large crop of fine berries which sold at 1s. per quart, yielding at the rate of 100 bushels per acre. Other plantations, not mulched, gave 20 or 25 bushels to the acre.

Newspaper Coverings and Frost.—I have had much experience of the value of newspapers as a protection from frost, in the case not only of plants, but also in that of Apples and Potatoes, and I have always found them serviceable. Laid lightly over plants that are even in height, they not only exclude frost but also drip. They should be laid on in the evening, and not be removed until after the frost is entirely thawed next morning, when they should be thoroughly dried and rendered fit for use next evening. In small unheated houses, such protections are useful in warding off moderate amounts of frost. In Apple and Potato stores such coverings need not be removed until all danger from frost is past. The value of paper coverings, however, depends greatly upon the construction of the shed or store, as, if it admits frost at every joint, it will require something more substantial than newspapers to keep fruit, at least, safe. Moreover, if Apples or Potatoes be stored on open or trellised shelves, even with a thin layer of straw on them, it will be seen that they are doubly exposed; but, if the shelves consist of stout boards set close, and a layer of straw is also used, then a good close covering of newspapers will be of great value in excluding frost.—A. D.

Grafting with Fruit-bearing wood.—I have been in the habit for a number of years of practising the different modes of grafting nearly all kinds of fruit trees, and have often found the shoots to flower the same spring. Three years ago I took a fine healthy shoot about a foot long with fruit-buds and spurs from 2 to

4 inches long from an old tree of the *Magnum Bonum Plum*, and put it upon a strong healthy stock. With a little extra care, it took very kindly, flowered, and set freely. I thinned the fruit down to half-a-dozen, which ripened and were quite as large as any on the parent tree. The next year it grew very strongly, and made shoots from 2 to 3 feet long, but no flowers. This year it bore a very fair crop. I may add that the tree is in a pot, and that every attention has been paid to it.—J. G. T. COCKS, in the "Gardeners Magazine."

The Newtown Pippin at Home.—The discussion on this Apple at the late pomological meeting at Chicago, was of an interesting and somewhat conflicting character. In Virginia and North Carolina it succeeds admirably, but not on the lowlands. Hundreds of barrels are shipped from Washington. It does not bear well in Maryland. Mr. Ragan, of Indiana, stated that the green variety was the only one worth anything at the west, the yellow being worthless. Messrs. Breckenridge, of Maryland, and Overman, of Illinois could not find two varieties. Messrs. Barry, of New York, and Hovey, of Boston, thought the two were only different conditions of the same Apple. Mr. Ragan found the trees identical in the nursery and orchard growth, but the yellow variety bears a larger Apple, which does not keep well. To these opinions we may add the remarks of the late Mr. Charles Downing, who stated that "the yellow is handsomer than the green, and has a higher perfume; the flesh is rather firmer and equally high flavoured. The green is more juicy, crisp, and tender. The yellow is flatter. Both grow alike."—"Albany Cultivator."

A Famous Vineyard.—The famous Clot Vougeot is a remarkable instance of the prolonged fertility of a Vineyard with but little artificial aid. In A. D. 901, the "Clos" was a waste of about 145 English acres, of which a couple of acres were set with Vines. About this time the Benedictine monks, and afterwards the Bernardines, who came into possession of the land, began clearing. The surface blocks of stone which covered much of the ground, and were rarely found adherent to the subjacent rock, were removed and formed into piles. The soil was levelled and dug to a uniform depth of 16 inches or so, and the ground set out with Vines. By-and-by, hollows and irregularities were filled up with stones from the piles, with a light covering of soil, and planted in like manner, as were also the sites of the piles themselves. The last Vines were planted in 1234, and are still known as the "young Vines." This is no fancy sketch. The history of the ground has documentary evidence to vouch for it, and what is more, the details of the planting are still distinguished by the Vintagers. It has been said that the Vines propagate themselves. As the old rods are headed down they leave in the ground stools, which appear to be almost proof against decay. These stools form a sort of continuous carpet about 12 inches below the surface of the soil, being thickest under the Vines of 904, and thinnest under those of 1234.

PEARS IN THE NORTH-MIDLAND DISTRICT.

MR. W. INGRAM, of Belvoir, has some notes (in the "Farmer") on his experience of Pears, which may be read with profit by readers having gardens in situations not quite favourable for the growth of that fruit. Soil, climate, and local situations exert so great an influence on the growth, character, and quality of fruit crops, that the recorded experience of fruit growers in any special department, like that of Pears, for example, is not unfrequently useful even to the professional gardener, and is calculated to be of much greater service to the amateur, particularly if he is about to establish, or add to, his collection of fruit trees. Fruit manuals and nursery catalogues must necessarily contain the names of the kinds of Pears cultivated throughout the country, and without some information to guide him, a young grower may make many serious mistakes in selecting his trees, as Pears of great excellence in the south and south-west of England are quite unsuitable for the northern counties. The question as to the stock on which the Pear is worked is one that has to be considered in relation to the position the tree is to occupy. In relating my own experience of the character of the Pears I have fruited and fairly proved, I may first say that in this north-midland district we do not enjoy any special advantages of climate or soil, and our rainfall averages 24 inches. My Pear season commences by ripening on an east wall about the middle of July, a rosy-cheeked handsome little Pear called *Johemont*, succeeded immediately by *Doyenné d'Été*, and followed by *Citron des Carmes*. In August, that very useful old Pear, the *Jargonelle*, ripens, and a handsome, but not very remarkable Pear for quality, *Poire Pêche* follows. Four very good Pears ripen with me in September—*Beurré d'Amalnis*, *Williams's Bon Chrétien*, *Dunmore*, and *Fondante d'Antonne*. The number is much extended in October; amongst the best may be named *Louise Bonne de Jersey*, *Beurré Hardy*, *Doyenné Boussoch*, *Flemish Beauty*, *Marie Louise*, *Beurré Superfin*, *Wel-*

beck Burgundy, *Gansel's Bergamot*, and *Urbaniste*. As the winter season approaches the number of Pears that attain maturity is still further extended, and November affords amongst others that fine old Pear which has the property of keeping firm and good several weeks after perfect ripening, a quality that many of our best Pears lack most lamentably—*Crassane*; then follow *Soldat d'Espereu*, *Beurré Capiamont*, *Beurré Clairgeau*, *Beurré Bosc*, *British Queen*, *Van Mons Leon Le Clerc*, *Beurré d'Anjou*, which are among the most noticeable this period affords. A little hardy but excellent Pear, called *Aston Town*, ripens early in the month, and is best grown as an orchard tree. Some of the very best Pears ripen, as they should do, about the festive season of Christmas, when other fruits become scarce, and are therefore doubly welcome. In December *Winter Nélis* is generally in perfection, and is one of the best Pears we possess. *Conseiller de la Cour*, *Doyenné du Comice*, *Glou Morceau*, *Hacon's Incomparable*, *Josephine de Malines*, *Huyshe's Prince Consort*, *Beurré Bachelier*, afford examples calculated to grace any dessert, and please the most fastidious taste. In January *Winter Nélis* is still pre-eminent for high quality, and the gradual ripening of *Josephine de Malines*, *Prince Napoleon*, *Jean de Witte*, *Knight's Monarch*, *Zéphirin Gregoire*, *Passé Colmar*, *Orpheline d'Engbien*, adequately keep up the supply, which is continued throughout the two following months by *Knight's Monarch*, *Éclair*, *Beurré*, *Doyenné d'Alençon*, *Olivier de Serres* (a capital Pear), *Bergamot d'Espereu*, *Ne Plus Meuris*, and *Beurré Rance*.

Rea's Mammoth Quince.—*Rea's Mammoth*, a sub-variety of the *Orange Quince*, is highly recommended as being much larger than the common variety, and more productive. The fruit is tender throughout, like an Apple, and free from the hardness and harshness of the Pear Quince. Those who have grown *Rea's Mammoth* for two or three years say it is so much larger and more productive than other varieties that it is destined to displace them. All varieties of Quinces are very hardy. As the blossoms do not appear till June, there is never any danger of injury from late spring frosts. Quince trees may be transplanted at one, two, three, five, or even more years old, of course taking care to injure the roots as little as possible. An old tree may thus be transplanted, but the fruit should be picked off the first year and a full crop can be had the next. But young trees are so much cheaper, and come into bearing so soon, that for a large plantation they are preferable. My way has been to buy very few Quince trees, except to get a new variety, as *Rea's Mammoth*. They are propagated very readily from layers, and by cutting off the young shoots, leaving ten or more buds at the base, and earthing around these, at the end of the year these buds will be vigorous shoots, well rooted, and ready to plant in the orchard.—"Cultivator."

Ferments in Flowers and Fruit.—According to M. Blondeau, during the flowering of certain plants, we observe an elevation of temperature, accompanied by a disengagement of carbonic acid, which has led certain authors to say that at this part of their existence plants respire in the same manner as animals. In fact, at this period, the sugar stored up in the plant undergoes alcoholic fermentation, and the alcohol formed is burnt, and in burning produces the heat needful for reproduction. When a fruit—*i.e.*, an Apple or a Pear—has reached maturity, and after being detached from the tree is placed in a vessel of lime-water, the turbidity which appears in the water proves that a development of carbonic acid is taking place. If the fruit, which has thus lived for some time in the absence of air, is submitted to distillation, a notable quantity of alcohol may be obtained, as shown by M. Leclathier and Bellamy in their researches on the ripening of fruits. Even the simplest vegetables—Algae, Lichens, and Fungi—contain, during all the course of their existence, alcohol pre-formed, the combustion of which serves to maintain the heat needful for their existence.

Fruit as Food.—Fruit should be eaten as food, not as a mere pastime; it should be eaten at the table, as a portion of the regular meal; but sparingly at late meals. All cooked food impairs the power of the stomach to digest uncooked substances; therefore, so long as we are accustomed to cooked food, we must be careful in regard to the times when we eat fruits in their natural state. Hence so long as we are accustomed to cooked food, the stomach will always digest fruit in its natural state better in the early than the latter part of the day.—SYLVESTER GRAHAM.

Burying Grapes.—Mr. Quinby stated to the Western New York Farmers' Club, that he buried some boxes of Concord, Catawba, and Delaware Grapes, on the 1st of December, and on being taken up the middle of the succeeding February they were found to be good, free from mould, with a perfect aroma. Much of the success of this mode of keeping would depend on the natural drainage of the soil, as well as on the previous and subsequent condition of the weather as to dryness.

TREES AND SHRUBS.

THE MAHONIAS OR PINNATE-LEAVED
BERBERRIES.

By GEORGE GORDON, Author of "The Pinetum."

WHETHER the genus *Mahonia* is sufficiently distinct or not from that of *Berberis* is a much disputed point among botanists, who look to the formation of the flowers for the distinction, while every practical gardener can distinguish the difference between them at first sight, the *Mahonias* having pinnate leaves, spineless stems, and berries containing from three to seven seeds in each; the *Berberis* having, on the other hand, simple leaves, spiny branches, and rarely more than two seeds in each fruit. All the species of *Mahonia* are strictly evergreen, and form handsome shrubs at all seasons of the year, but especially in the spring when in flower, and in the autumn when furnished with their deep purple berries.

Group 1.—Natives of Japan, China, and the North of India.

The Japan *Mahonia* (*M. japonica*).—This is a robust branching shrub, from 6 to 8 feet high, with leaves from

A Pinnate-leaved Mahonia.

12 to 15 inches long, thick, leathery in texture, usually with four pairs of leaflets and the usual terminal odd one; leaflets, large, broadly ovate, sessile, slightly cordate at the base, rather closely placed along the leaf-stalk, from $2\frac{1}{2}$ to $3\frac{1}{2}$ inches long by 2 inches broad, and with from three to four strong spiny teeth on each side. They are of a dark shining green on the upper surface, pallid beneath on the younger-leaves, but frequently tinted with purple on the older ones before they fall; the lower pair of leaflets are also much the smallest and are placed close to the base of the petiole, while the terminal one is much the largest, frequently measuring $3\frac{1}{2}$ inches in length and from $2\frac{1}{2}$ to 3 inches in breadth, with a very stiff, triangular, spiny point. The flowers are rather large, of a bright yellow, and are produced in numerous dense, terminal, upright, simple racemes, from 4 to 6 inches long, which issue from among the broad, acute-pointed, persistent scales of the terminal buds. The berries are oval or roundish, large, and deep purple, covered with a fine glaucous bloom. This kind is found both in the northern parts of China and in Japan, and is called *Sasa Nanjing* by the Japanese. Mr. Fortune first met with it in 1848 in an old Chinese garden, in the

district of Hwuychow, a place famed for its green teas, and from 100 to 150 miles north of Shanghai. It is perfectly hardy.

Three-forked-leaved *Mahonia* (*M. trifurca*).—This kind forms a bush from 4 to 6 feet high, with leaves from 12 to 15 inches in length, thick and leathery in texture, and with from seven to nine pairs of leaflets, and an odd one. The leaflets are oblong-lanceolate, $2\frac{1}{2}$ inches long and $1\frac{1}{2}$ inches broad, with the lower pair much the smallest and close to the base of the petiole, and the terminal one frequently tritricate. The other leaflets are distantly placed along the leaf-stalk, are sessile, truncate at the base, bright yellowish-green, pallid beneath, and five-nerved, and with from three to four sharp spiny teeth on each side. The flowers, which are bright yellow, and produced in numerous dense erect racemes, from 4 to 6 inches long, issue from among the scales of the terminal buds in April. The berries are oval, rather large, and deep purple, covered with a glaucous bloom. It is a native of the northern parts of China. Mr. Fortune first met with it in a cottage garden, and was informed that it was cultivated extensively in the province of Chekiang, on account of the dye which it furnished. This kind bears considerable resemblance to the Nepal variety in the greater number of its leaflets; but differs from it in its much thicker and more leathery leaflets, and in the young shoots being covered with scales of a clear reddish-purple, a colour which gives them a very marked appearance. It is quite hardy, and is sometimes named *Mahonia intermedia*, *Bealii*, and *japonica intermedia*. Lindley considered this kind a distinct species; but it appears to be little more than a variety of the *Mahonia japonica*.

Fortune's Chinese *Mahonia* (*M. Fortunei*).—This kind forms an upright shrub from 4 to 6 feet high, with several stems, which become naked when old, and with but few branchlets. The leaves are frequently 9 inches long, dark green, with a bluish tint on the upper surface, and with from three to four pairs of distinct, sessile, long, narrow leaflets, and an odd one, the three upper ones being always close together. The leaflets are narrowly lanceolate, tapering much to the point, wedge-shaped at the base, frequently 4 inches long, and half-an-inch broad, with from sixteen to eighteen distinct, straight, shallow, spiny serratures on the margins, pointing towards the apex of the leaflet. The flowers are small, light yellow, and produced in numerous closely-arranged terminal erect racemes $2\frac{1}{2}$ inches long, which rise from among the brown scales of the terminal buds in the spring in England, and in the autumn in China; the berries, which are dark purple, are in terminal paniced racemes less than half the length of the flowers. It is a native of the northern parts of China, and tolerably hardy about London. Mr. Fortune found it cultivated in the Chinese gardens about Shanghai, where it is a favourite plant, and is called "Che-wang-chok," or the blue and yellow Bamboo, on account of the bluish tint of the leaves, the yellow colour of the flowers, and the naked appearance of the old stems, which somewhat resemble those of a Bamboo.

The Nepal *Mahonia* (*M. nepalensis*).—This kind forms an erect-growing shrub, from 4 to 6 feet high, with leaves from 12 to 18 inches long, and with from five to ten pairs of leaflets, and an odd one; the lower pair are much the smallest and close to the base of the petiole, the others being rather distantly placed along the leaf-stalks, and all are of a bright shining, yellowish-green colour. The leaflets are ovate, or oblong-lanceolate, about 3 inches long and 1 inch broad, cuspidate or frequently tricuspidate at the ends, gradually enlarging from the base, sessile, five-nerved, rounded or obliquely sub-cordate at the base, repandly toothed, with from five to ten strong spiny teeth on each side, and not nearly so thick and leathery in texture as the Japan kinds. The flowers are rather large, bright yellow, and produced in March and April, in numerous (sometimes twelve or fourteen from the same terminal bud) erectly-spreading, dense, simple racemes, occasionally 6 inches long, and which issue from among the brown scales of the terminal buds in fascicles. The berries are large, oval or oblong, dark purple, and covered with a fine glaucous bloom. It is a native of the mountains of northern India, particularly in Nepal and at Ootacamund on the Neilgherry range, and is said to extend as far to the eastward as the Manipure country. This kind is hardy in the neighbourhood of London, and there

is a fine plant of it in the pleasure grounds at Sion House, which has stood out there unprotected and uninjured for the last twenty years. Its synonyms are *Mahonia* and *Berberis acanthifolia*, *Micca*, and *Leschenaultii*.

Group II.—Natives of the North-western parts of North America.

The Chaffy-stemmed Mahonia (*M. glumacea*).—In England this kind forms a close bush from 12 to 18 inches high, but according to Torrey and Gray, the stem is so low in the wild state, that it often scarcely rises from the ground, and is at all times much shorter than the leaves. The leaves are nearly 18 inches long, erectly-spreading, pale green on the upper surface with reddish petioles, and usually with six pairs of leaflets and an odd one. Leaflets ovate, pointed, sessile, remotely spiny toothed, and with from twelve to fourteen teeth on each side. The flowers are pale yellow, larger than those of the common Holly-leaved variety, and are produced in March and April, in numerous simple, upright, spicate racemes, from 6 to 8 inches long, crowded with flowers, and rising from among the scales of the terminal buds. The berries are globular, deep blue, covered with a fine glaucous bloom and ripe in July. It is perfectly hardy and a native of North America on the western coast, in shady Pine forests at the mouth of the Columbia River, and on the Pacific coast, and derives its name from the stems being covered by the long persistent lanceolate scales of the leaf buds, which continue to clothe the stem like coarse chaff for many years. Its synonym is *Mahonia nervosa*.

The Creeping Mahonia (*M. repens*).—This kind forms a dwarf bush seldom exceeding 1 or 2 feet in height, the shoots of which consist chiefly of short unbranched suckers, and it owes its name to its great tendency to form what are called creeping roots under ground. It has leaves from 6 to 8 inches long, somewhat glaucous on both surfaces, and with from two to three pairs of leaflets and an odd one. The leaflets are rather large, roundish-ovate, not pointed, truncate at the base, entire or obscurely toothed on the edges, of a dull glaucous green, and about 2 inches long and $1\frac{1}{2}$ broad, with the lower pair very distant from the base of the petiole, and the terminal one much the largest. The flowers are of a rich yellow colour, in numerous short, diffuse, fasciated-racemes, which rise from among the scales of the terminal or axillary buds in April. The berries are globular, and deep purple. It is a native of North-west America, on the east side of the Rocky Mountains at the junction of the Portage river with the Columbia, and is said to extend into New Mexico. This kind, which is considered by some botanists as only a wild form of the common Holly-leaved one, crosses freely with that kind, and has produced several varieties, all of which have the large round leaves and dull glaucous green colour of the creeping *Mahonia*. It is quite hardy, but one of the least ornamental.

The Common Holly-leaved Mahonia (*M. Aquifolium*).—This kind forms a many-stemmed bush from 4 to 8 feet high, of which there are numerous forms, which differ chiefly in the size and shape of the leaflets, but none of them are so fine as the original one first introduced by Douglas from the Rocky Mountains. The leaves are from 6 to 9 inches long, with from three to four pairs of leaflets and an odd one. The leaflets are ovate, pointed, flat, equal in size, $2\frac{1}{2}$ inches long, and rather more than an inch broad, sessile and slightly rounded at the base, spiny toothed on the margins, with from six to nine serratures on each side, of a rich deep shining green colour on the upper surface, not closely placed along the leaf-stalk, and with the lower pair remote from the base of the petiole. The flowers are in erect, much crowded, short terminal racemes, of a bright yellow colour, and produced in April and May. The berries are globular and deep purple, thickly covered with a fine glaucous bloom. It is found in woods all over the North-western parts of North America, from New Albion to Nootka Sound, and is abundant along the banks of the Columbia River in rocky places, and in the Oregon territory.

Group III.—Natives of New Granada, Mexico, and California.

Hartweg's Mahonia (*M. Hartwegii*).—This is a beautiful shrub, from 5 to 6 feet high, with large, deep, lucid green leaves, often 18 inches in length, and with from eleven

to thirteen leaflets. The leaflets are ovate-lanceolate, flat or very slightly undulated on the edges, spinosely-serrated or entire on the margins, sessile or roundly truncate at the base, closely placed along the leaf-stalks, and from 3 to $3\frac{1}{2}$ inches long and $1\frac{1}{2}$ inches broad. The flowers are in ramosely-panicled, elongated, loose racemes, frequently a foot in length, with alternate forked branches, having from three to fifteen flowers on each, on short pedicels, of a deep yellow colour, and produced in great profusion in April and May. The berries are globular and deep purple. It is a native of Mexico, on the Rancho de los Gallitos, a narrow valley situated on the eastern declivity of the great table-land between Zacatecas and the mining district of San Louis Potosi, also in the valley of Los Gallitos, on the ascent from San Barbara, on the road from Tampico to San Louis Potosi, and at the foot of a bluff rock called El Contradero, between Tulo and San Barbara. It is too tender for the open border about London, and should be treated as a greenhouse or conservatory plant.

The Lance-leaved Mahonia (*M. lanceolata*).—This forms a handsome, erect-growing shrub, from 5 to 6 feet high, with straight, stiff, erectly-spreading leaves from 6 to 9 inches long, and with from thirteen to seventeen leaflets of a deep green colour, somewhat lucid on the upper surface; leaflets, long, narrow, lanceolate, slightly undulated on the margins, very acute pointed, sessile and wedge-shaped at the base, quite straight, rather closely placed along the leaf-stalk, from 3 to 5 inches long, and from $\frac{1}{2}$ to $\frac{3}{4}$ inch broad, regularly, spinosely serrated on the edges, and with the lower pair remote from the base of the petiole. The flowers are in long, loose, branching racemes, a little shorter than the leaves, of a bright yellow colour, and produced in April and May. It is a native of Mexico, where Mr. Hartweg found it inhabiting the mountain ravines of Apulco and at El Contradero, between Tulo and San Barbara. This kind, like the last, is too tender for the open border in the neighbourhood of London, and should be treated as a greenhouse plant.

The Slender-leaved Mahonia (*M. tenuifolia*).—This forms a handsome shrub, from 10 to 12 feet high, with a single stem, and leaves from 9 to 12 inches long, spreading or bent downwards when fully developed, and with from four to five pairs of leaflets and an odd one; the leaflets are ovate-lanceolate, short, thin in texture, pale bright green, perfectly free from all traces of toothing on the margins, distantly placed along the leaf-stalk, from $2\frac{1}{2}$ to 3 inches long, and $\frac{1}{2}$ inch broad, and with the lower pair remote from the base of the petiole. The flowers appear in simple, erect or nodding, open slender racemes, frequently a foot or more in length, naked at the base, and issuing from the terminal buds. They are on long pedicels, bright yellow, agreeably sweet-scented, and are produced in great abundance from October to December. The berries are globular, nearly black, and in drooping racemes, often a foot in length. It is a native of the warm climate of Vera Cruz and Zaquapan, in Mexico, at an elevation of not more than 3,000 feet on the eastern declivity of the snow-clad Orizaba, and is so tender that it must be regarded strictly as a greenhouse plant. Its synonym is *Mahonia fraxinifolia*.

The Pallid-flowered Mahonia (*M. pallida*).—This forms a fine shrub from 6 to 8 feet high, usually with a single stem, and rather slender leaves, from 6 to 8 inches long, and with from eleven to thirteen leaflets of a dry, hard texture. The leaflets are ovate or ovate-lanceolate, undulated, and irregularly spiny-toothed on the margins, sessile, rounded or somewhat wedge-shaped at the base, distinctly placed along the leaf-stalk, of a pale yellowish-green colour, and from $1\frac{1}{2}$ to 2 inches long and 1 inch broad. The flowers are in loose, slender, open, branching racemes, 8 or 10 inches long, at first erect, but afterwards, when fully developed, nodding at the ends. The flowers have whitish sepals, small pale yellow petals, and are produced in threes at the ends of the secondary branches of the flower-stalk during the months of January and February. The berries are globular, deep purple or nearly black, and ripe in July. It is a native of Mexico, and is found at an elevation of 8,000 feet at the hot springs of Atotonilco el Grande, near Real del Monte, on the Cardonal la Najada, San Jose del Oro, and Zacualtipan, and is about as hardy as *M. fascicularis*. Its synonym is *Mahonia Ehrenbergii*.

The Slender-branched Mahonia (*M. gracilis*).—This forms a very pretty shrub, 5 or 6 feet high, with slender branches, and leaves from 3 to 5 inches long, having bright red petioles, and from three to five leaflets. The leaflets are ovate or ovate-lanceolate, sessile, dry, and hard in texture, slightly undulated, and denticulately spined on the margins, wedge-shaped at the base, rather distantly placed on the leaf-stalk, from 1 to 1½ inch long and ¾ inch broad, of a bright shining green on the upper surface, somewhat three-nerved beneath, and with the lower pair remote from the base of the petioles; the flowers are rather small, deep yellow, and produced in March and April in numerous simple, sub-fasciculated, open racemes, 3 inches long with bright red pedicels; the berries are globular and deep purple. It is a native of Mexico, near the hot springs of Atotonilco el Grande, on the barren hills of Zimapan, the Cardonal Mountain, near Real del Monte, near the village of Santa Maria, and on the Vulcan de Aguc, in Guatemala, at an elevation of 9,000 feet. This kind is too tender for the open border in the climate of London, but is an effective object when planted at the base of a south wall.

The Crowded-racemed Mahonia (*M. fascicularis*).—This kind forms a handsome, robust, many-stemmed bush, with leaves from 6 to 8 inches long, of a dull glaucous green, and with from three to five pairs of leaflets and an odd one. Leaflets, ovate-lanceolate, very rigid, wavy or somewhat twisted, sessile, rather distantly placed along the leaf-stalk, with the lowest pair near the base of the petiole, spiny-toothed on the margins, with four or five prickly teeth on each side, and of a dull glaucous green colour; the flowers are in large, terminal, erect, much crowded, and compact racemes, of a deep yellow colour, and produced in April and May; the berries are oval and deep purple. In its native state this kind is chiefly confined to the lowlands of California and North Mexico. Mr. Hartweg found it on the Gigante, the highest point of the range of mountains of Guanajuata, in Mexico, and near Monterey, in California. It is too tender for the open border near London, but makes a fine shrub for training against a conservatory wall. Its synonym is *Berberis pinnata*, and there is the following hybrid variety.

The Hybrid Mahonia (*M. fascicularis hybrida*).—This kind forms a robust many-stemmed bush, from 5 to 8 feet high, with quite the arborescent habit and general aspect of *M. fascicularis*. The leaves are from 6 to 8 inches long, with from four to six pairs of leaflets, and an odd one; they are also of a deeper green than those of *M. fascicularis*. The leaflets are ovate, pointed, and distant along the leaf-stalks, from 1½ to 2 inches long, and about 1 inch broad, sessile, truncate, or slightly rounded at the base; a little wavy, and spiny-toothed on the margins; with from eight to ten regular, coarse, angular serratures on each side, and of a bright green; a little lucid on the upper side; and much larger and thinner than those of *M. fascicularis*. The flowers are deep yellow, and are produced in great profusion in April and May, on short, simple, dense racemes in terminal close fascicles. Berries, globular, deep purple, and only sparingly produced in short clusters. It is perfectly hardy, and very superior to any of the forms of *M. Aquifolium*; it is said to be a hybrid production raised between *M. repens* and *fascicularis* in the nursery of Mr. Rivers, of Sawbridgeworth, in Hertfordshire. Its synonyms are *Mahonia repens-fascicularis* and *M. Aquifolium-fascicularis*.

The New Granada Mahonia (*M. Tolumensis*).—This kind forms a robust many-stemmed bush, 5 or 6 feet high, somewhat resembling *M. fascicularis*, but with slender bright green leaves from 8 to 10 inches long, and with from five to six pairs of leaflets and an odd one, which is sometimes the largest, and 4 inches in length; leaflets, ovate-lanceolate, acute-pointed, and distantly placed along the leaf-stalk, with the lower pair remote from the base of the petiole; they are sessile, a little rounded, or obliquely truncate at the base, thin in texture, flat, slightly undulated on the edges, and from 2½ to 4 inches long, and from ¾ to 1 inch broad, regularly spiny toothed on the margins, with from eighteen to twenty slender sharp serratures on each side, and of a bright green, a little lucid on the upper surface; the flowers are deep yellow, and produced in racemes in April and May. It is a native of the mountains of Tolu, in New Granada,

and about as hardy as *M. fascicularis*. Its synonym is *Berberis Toluensis*.

The Narrow-leaved Mahonia (*M. angustifolia*).—This kind forms a neat, slender, upright shrub, from 4 to 5 feet high, with leaves from 3 to 5 inches long, and with from four to six pairs of leaflets and an odd one; the leaflets on the adult plants are oblong-lanceolate, very small, narrow, and acute-pointed, while those on young plants are much broader and less pointed; the leaflets are rigid, sessile, somewhat undulated and spiny-toothed on the margins, rounded or a little tapering to the base, nearly an inch long, and 2 or 3 lines broad, with four or five regular, sharp, spiny serratures on each side, and the lower pair of leaflets near the base of the petioles and remote from the others, which are somewhat distantly placed along the leaf-stalk, and all of a light glaucous green, with a bluish tint on the upper surface; the flowers are small, in short, dense fascicles, on rather longish pedicels, bright yellow, and produced in March and April; the berries are globular, light red, with a glaucous bloom and sweet-tasted. It is a native of New Granada, and of the mountains between Pachuca and Actopan in Mexico, and is about as hardy as *M. fascicularis*.

The Three-leaved Mahonia (*M. trifoliata*).—This very beautiful and distinct species forms a branching shrub from 3 to 4 feet high, with leaves from 3 to 3½ inches long, having three terminal, sessile leaflets, beautifully marbled with blue, dull green, and delicate pale veins, the slender leaf-stalks being sometimes 2 inches long; the leaflets are in threes, ovate, acute-pointed, rigid, sessile, wavy, and spiny-toothed on the margins, with from three to five coarse, sharp, angular, spiny sinuosities on each side, rounded, and a little tapering to the base, from 1 to 1½ inches long, and ¾ inch broad, of a glaucous blue colour, marbled with dull green on the upper surface, as has just been stated, and light green beneath. The flowers are rather small, bright yellow, and produced in April and May in few-flowered axillary racemes on short peduncles. The berries are small, globular, light red, and sweet-tasted. It is a native of Mexico, where it is found covering large tracts of the high table-land near the Hacienda del Espiritu Santo, an immense plain on the road from Zacaticas to the mining district of San Louis Potosi, and is called by the inhabitants "Acrito;" the fruit, which is rather sweet-tasted, is much eaten by children. It is rather too tender for the open border about London, but makes a beautiful plant for training against a south wall.

The White Evergreen Thorn.—This plant (*Crataegus Pyracantha alba*) is very highly spoken as a hedge plant in "Moore's Rural." Among the many plants experimented with for hedges in the eastern states, the White Evergreen Thorn (*Crataegus Pyracantha alba*) is certainly the most promising. In the grounds of Messrs. Parsons, of Flushing, where it has been growing for the past fifteen years, it thrives admirably. Old specimen plants (of which there are many) standing upon the lawn form naturally a dense mass. So closely interwoven is the small Thorn-studded spray that a sparrow would find it difficult to enter or pass through. The plants bloom in June, and in autumn and winter they are covered with very showy orange-coloured berries. The Evergreen Thorn is a slow grower, seldom producing young shoots of more than 12 to 18 inches in length in one season; but the plants fill up as they progress, consequently require very little pruning, and when fully established, no ordinary animal would ever make more than one attack upon their thorny surface. This variety of *Pyracantha* should not be confounded with the more common sort, which has round leaves, and is not hardy. The White Evergreen Thorn has small, oblong, pointed leaves, and they remain permanently upon the plant during the coldest winters. It is propagated by cuttings and layers, and hedges should be formed with one or two-year-old plants, as older ones are not so readily transplanted, owing to their strong, deeply-penetrating roots. It is also necessary to plant in autumn or very early in spring, as the sap moves the first warm weather; and after growth has commenced there is great danger of loss in removing.

Plant Poisoning.—Numerous authenticated cases are on record in which horses and cattle have been poisoned by eating Yew leaves; horses which have eaten *Acacia* buds and Laurel leaves have died of violent intestinal inflammation; both Yew and Laurel are much more dangerous in the months of May and June than later, because the new shoots contain a much larger quantity of prussic acid. *Rhododendrons* have been known to poison goats, and the *Andromeda* cows.

THE KITCHEN GARDEN.

REPORT ON ONIONS GROWN AT CHISWICK.

SEED for this trial, which took place at Chiswick this year, was furnished by the following, viz.—Messrs. Barr & Sugden, Carter & Co., Cutchub & Son, Benary (Erfurt), Nutting & Son, Sutton & Sons, Veitch & Sons, Yilmorin & Co. (Paris), Harrison & Sons, Stuart & Mein, Piccirilli, Hovey & Co. (Boston), Danvers, J. Perry, A. A. Parsons, and R. Dean. The seed was sown on March 16th in well pulverised moderately rich soil, which had, the previous season, been well manured for Celery. The season was, on the whole, favourable for the growth of Onions, so that the trial was, so far, of a very satisfactory character. Altogether 155 samples were sown, representing ninety-eight different names, of which number twenty are here described as quite distinct. The report only extends to those varieties which have been proved to be well adapted for spring sowing and early autumn or winter use, the remainder of the Tripoli and Silver-skinned sections being again submitted for trial as autumn-sown Onions.

1. White Spanish [syns., Banbury (Perry), Banbury Improved, Nuneham Park, Improved Nuneham Park, Reading, Improved Reading, Nazeby Mammoth (Carter & Co.), Oxonian Prize (Nutting & Son), Cutchub's Al (Cutchub & Sons), Portugal, Cantello's Prize (Waite, Burrell, & Co.)].—This variety is the one most generally cultivated. The plant is of free growth, the neck of medium size, and ripens off early and well. The bulbs are large, a fair-sized specimen measuring about 12 inches in circumference, and from 2 to 2½ inches in thickness. The shape is flattened, the base broad, flat, frequently a little hollowed and uneven, somewhat globular towards the stalk in the best forms. Skin pale straw, falling off readily and exposing the pale greenish-yellow outer flesh. The flesh itself is firm and solid, almost white, and of excellent quality. This variety keeps generally in good condition up to the month of March. The Banbury and Nuneham Park types were the most approved.

2. Large Straw-coloured (Yilmorin)—[syn., Yellow Flat (Hovey & Co.)].—This is only to be distinguished from the White Spanish by the darker colouring of the outer skins.

Yellow Lescuré (Yilmorin), Yellow Cambrai (Yilmorin).—These were considered very spurious stocks of the large Straw-coloured.

3. White Globe.—Plant of free growth, forming in general a small neck; ripens off early and well. The bulbs are of medium size, from 9 to 10 inches in circumference, and about 2½ inches in depth. The shape is somewhat globular or obovate, with a finely rounded high crown. The skin is pale straw, much like the White Spanish, and it is, indeed, similar to that variety in every other respect, but its more globular form. It is an excellent keeping sort, and much esteemed.

White Intermediate and Oscar (Cutchub & Sons).—These are mixed and indifferent stocks of White Globe and White Spanish.

4. Trebons (Yilmorin & Co., Stuart & Mein).—Plant of free growth but somewhat tender, succeeding best in a warm season. Neck somewhat gross. The bulbs are of very large size—about 13 inches in circumference, and from 3 to 3½ inches in depth. The shape is obovate, the base somewhat broad and flat, (twilight the top tapers more to the stalk or neck. The skin is pale straw, and peels off readily like that of the White Spanish. The flesh is pale and rather soft and flabby, but of mild and excellent quality. This is a very large and handsome Onion for early autumn use. It does not keep well, and generally begins to shoot before Christmas. It bears a close resemblance to the imported Spanish Onions.

5. Yellow Danvers (Hovey & Co., Yilmorin & Co., Carter & Co.) [syn., Dauvers' Yellow].—This is a very fine and distinct Onion. The plant is of free growth, the top slender, of a rather pale green colour, and with a very fine slender neck, so that it ripens off well. The bulbs are of medium, but very even and regular, size, from 10 to 11 inches in circumference, and about 2½ inches in depth. The shape is roundish-globular, very regular, with a small base and a small neck. The skin is of a dark straw colour, the outer coating peeling off freely, but not exposing the flesh, the inner coating remaining firm, giving the Onion a very neat, clean appearance. The flesh is very firm and solid throughout, and of fine quality. A splendid keeping variety.

New German (Veitch & Sons).—This bears a close resemblance to Danvers' Yellow, but scarcely appears to keep so well.

6. Brown Globe (syn., James' Keeping).—This is of the same character as the White Globe, but has darker or reddish-brown skins; some are pale-fleshed throughout; others, these being the darker-skinned, have a slight shading of red as an outside coating of the various layers as in the red varieties. It is an excellent keeping variety, and much esteemed. The James' Keeping of some is more flattened near the crown, forming a sort of shoulder to the stalk, and of others again it is similar to the Pear-shaped.

Magnum Bonum (A. Parsons) is a fine selection of the Brown Globe.

Brown Intermediate, Berwicksire Champion.—These are mixed stocks of Brown and White Globe.

7. Pear-shaped [syn., Pyriforme].—This is allied to the Globe section, and may be described as an elongated form of that variety. The plant is of free growth, the great majority producing very thick necks with very little bulb, so that they do not ripen off well. The true form is like that of a long Pear tapering mostly towards the stalk from 7 to 8 inches in circumference, and from 4 to 5 inches in depth or height. The skin is of a dark reddish-brown, and falls off readily. The flesh is moderately firm and is not a very good keeping sort, and its shape does not recommend it. A good selection of this is sometimes sent out as James' Keeping.

8. Deptford [syns., Brown Spanish, Improved Brown Spanish, Strasburgh, Strasburgh Dutch, Pale Red Nicot, Light Red Strasburgh].—Plant of free growth and very hardy, forming a small neck, and ripening early. The bulbs are of medium size, flattened or oblate, of pretty even and regular form. The skin is of a dark reddish-brown colour. The flesh firm, solid, tinged with red. An excellent keeping variety.

9. French Strasburgh [syn., Pale Red St. Brieux].—This is distinct from the Deptford or English Strasburgh. The bulbs are smaller, of very uneven shape, and frequently split open into several crowns. They are of a dull reddish colour. They are very inferior varieties of the Deptford class.

10. Deep Blood Red.—Plant of free and hardy growth. Bulbs of medium or rather small size, flattened or oblate, and generally of very even and regular form. The outer skin is of a dull red colour; the inner coating of a deep glossy red. The flesh itself is pure white, it being only the outside coating of the various layers that are coloured, and these become paler towards the centre. It is very firm and solid throughout. This is the strongest-flavoured Onion, and the latest keeper. On these accounts it is a valued variety.

Blood Red.—This is simply a paler-skinned variety of the preceding, and the most common.

11. Wethersfield Red (Hovey & Co., Carter & Co., Benary & Son)—[syn., Bright Red Mezières (Yilmorin)].—Plant of free and robust growth. The neck small, ripens off freely. Bulbs large, flattened or oblate, very even and regularly formed, about 12 inches in circumference and 2 in depth. The outer skin is of a light dull red colour, and peels off freely; the inner coating being light purplish, shading greatly from the crown to the base, where it is very pale. The flesh is pure white, the outer surface of the coating only being coloured. It is very firm, solid, of mild and excellent quality, and keeps well. A remarkably fine and handsome Onion from America. The finest type of Red Onion.

12. Early Red (Hovey & Co.)—This is a rather early red variety. The bulbs are of medium size, flat, and of a very dull red colour. The flesh is firm and solid, and of good quality. It shows a tendency to produce several crowns, which burst and spoil the bulbs.

13. Two-bladed.—This name is given to denote its peculiarities of only producing two blades or leaves. These form small bulbs very early in the season, and soon ripen off. A great majority, however, grow into larger bulbs, and these have the ordinary number of leaves. The true two-leaved type has small roundish bulbs about an inch in diameter. The skin is of a dull yellowish-brown colour; the flesh, greenish-white, and frequently a little coloured. They are very firm and solid, and keep well. Its small size makes it useful for pickling purposes.

14. Teneriffe (Benary & Son).—This greatly resembles in appearance the smaller types of the Two-bladed.

15. Silver-skin (Nutting & Son) [syns., Silver-skin Pickling (Veitch), Early White-skinned (Benary & Son), White Round Early Hard Dutch (Yilmorin & Co.)].—The bulbs are of medium size, roundish oblate; a great many are apt to split open. The outer skin is pure white or silvery, peeling off freely and exposing the next coating, which is white with green veinings. The flesh is pure white, exceedingly firm, and solid. Keeps remarkably well, and is useful to those who prefer very white Onions. This is quite distinct from the Paris Silver-skin, which does not keep well.

16. Queen's Eyes (New Queen, Piccirilli's New Queen)—This is a very small and very early variety of the Silver-skinned section. It forms bulbs almost as quickly as a Radish, and has rarely more than two or three leaves. They were fully grown last season by the 1st of June, about fifteen days earlier than the White Italian Tripoli, which variety, in the late trial, it most nearly resembled. Many large and later-growing examples were observed in each sample, which, if the seed was not mixed, implies a tendency to deterioration. In this, as in other respects, it exactly resembles the Nocera, as introduced from Italy about thirty years ago, and the Florence White of earlier date.

N.B. All the section of Silver-skinned Onions, including the Queen, White Italian Tripoli, Marzajola, Nocera, Paris Silver-skin, Early White Naples, and White Lisbon, also the Giant Tripoli section, including the Giant Rocca, Red Sallow, Madeira, &c., which are found valueless as spring-sown varieties, will form the subject of a separate report when their respective merits have been tested as autumn or winter-sown Onions.

17. Potato Onion [syn., Underground Onion].—This is not propagated by seed. The small bulbs are planted in the ground like shallots, and around these a number of new bulbs are produced. The bulbs are of average size, of somewhat irregular shape. The skin reddish-brown, hanging very loosely. The flesh is tolerably firm and solid, and of fair quality. It does not keep well, but is useful for procuring an early supply.

18. Egyptian [syns., Egyptian Bulbiferous, Tree Onion, Garden Rocambole].—This variety when planted throws up a stem on which, instead of flowers, small bulbs are produced of about the size of small marbles, which are very excellent for pickling. It is propagated by planting these bulbules (the largest of which will bear bulbs the same season) or by the bulbs which are formed in the ground, and which have not formed stems.

19. American Perennial Tree, or Top Onion (Carter & Co.)—This produces small bulbules in the same manner as the Egyptian Bulbiferous, but of a smaller and inferior character. No bulbs are formed in the ground. The plant is perennial, the roots long and fibrous.

20. Welsh.—Of this there are two varieties, the Red and the Green. The plant is an herbaceous perennial, and forms no bulbs; the roots are long and fibrous. The green tops or leaves only are used. It may be propagated by seed or by division of the roots. A. F. BARRON.

CULTURE OF CELERY.

Good Celery is still the exception rather than the rule in the majority of small gardens. Therefore no excuse can be needed for once more advertising to its cultivation. Spring Celery for soups, planted out in September and even in October, should not be earthed up till the following spring. They must be protected during winter by a little litter or a few leaves around their stems, and earthed up in February, such Celery is seldom first-rate for cheese or salad, but is most useful in other ways, as it is found almost impossible to preserve Celery blanched before winter after the following March. It either rots or bolts, whereas the late planted crops, unblanched during winter, may continue sound till May or even June. By that time green Celery, sown in January and February in heat and brought on, will be forward enough for flavouring, while it is possible to have blanched Celery early in August, so that Celery for flavour, at least, if not for cheese, may thus be had all the year round. To ensure this succession, three or four crops of seeds should be sown in a season. The first in January, to plant out in the middle of May, to come in early in August. This crop is much given to "bolting," and should be a small one. The second in March, to plant out in June, to come in through September and October. This crop generally does well, and should be a large breadth. The third in April, to plant out in July, to come in in October, November, and December; and the last crop, early in May, to plant out through July and August, to come in through January February, and March. In addition to these a small crop may be sown at the end of May or beginning of June, and planted out in September and October, as already described, for spring Celery. In the majority of gardens two sowings only are made—one in February, for the earliest, and a second in March or April for the main crop. To have large Celery it is needful to sow pretty early to give the plants time to grow into bulk during the warm weather. For though the Celery is a hardy plant it grows but slowly, and little in a temperature under 55° or 60°. In a wild state Celery is a marsh plant, and this fact gives the key to its culture, for though we change its uses we do not change its nature by cultivation. Therefore from the time the seeds germinate till the Celery is served in salad or with cheese, or used for flavouring soup, it should not once become dry. Dryness and poverty of soil constitute the surest means of ruining Celery crops. For marshes are not only moist, but, as a rule, they are remarkably rich with decomposing vegetable matter. In such, or its equivalent in the form of rich manure, Celery luxuriates and grows into size and quality if the cultivator will allow it. For next to the two modes already named the progressive earthing up of Celery is the surest mode of ruining it. It shuts out the water from the roots, envelops the plants in a mass of earth, and retards their growth. The object of progressive earthing up is, of course, to blanch the crop, an object by no means facilitated by the process; for Celery, to be of the highest quality—white, crisp, and sweet—should be all blanched at once. It should therefore be grown first and blanched afterwards. The simplest mode of blanching is by the use of earth, though paper cylinders, drain tiles filled with ashes, and other contrivances are often used to facilitate the process and to keep the stems straight and clean during its performance. A certain amount of shade is also helpful to the growth of Celery. This is generally effected by intercropping with Peas or Scarlet Runners. Let us, however, proceed to give some specific instructions, beginning with the sowing of the seed, and finishing with the taking up of the crop. Early Celery is, of course, sown in heat. The seed vegetates slowly, and comes up best in a temperature of 60° or 65°. Even in that temperature it will often take a month or six weeks to vegetate; while in a lower temperature it takes still longer. Whether sown in heat or out of doors it should be sown in light, rich soil, lightly covered, and kept moist through all its early stages. As soon as large enough to handle the plants should be pricked out—early crops in a hot-bed under glass, and late ones on a bed of manure formed in the following manner. Some use 60-sized pots for the first crop, so that the plants shall not be at all disturbed in being finally planted out in the trenches. In that case the pots are filled with rough half-rotten dung, and surfaced with soil, one plant being placed in

each pot. As soon as the roots fill the pots, the plants should either be shifted into others or finally planted out. On no account must the plants become much pot-bound, or they will run to seed. The more general practice is to make a bed of half-rotten dung about 6 inches thick on a hard bottom, and cover it with 1 inch of rich black vegetable mould. On this prick out the plants at distances of 4 or 6 inches square. Cover with glass or not, according to the season. Water and shade, if necessary, to prevent the smaller plants flagging. As soon as they get a fair hold they will make rapid progress, soon forming healthy leaves, and quickly filling their allotted spaces with a perfect network of roots. At any season after the middle of May till October, Celery may be successfully planted out. The most general mode of planting out is in trenches, at distances ranging from 2 to 6 feet, according to the width of the trench, and the mode of intercropping. The depth of the trench is also varied, the most common and convenient depth being from 12 to 18 inches, after being bottomed with at least 6 inches of good manure. A convenient width is 15 inches for a single row, 20 or 24 inches for a double line. Some also grow Celery in wide trenches and sunk beds, varying from 1 foot to 5 or 6 feet across, and plant the Celery in rows 9 to 12 inches apart, across the trenches. Of course the width of the inter-spaces will chiefly be determined by that of the trench, from 2 to 6 feet being convenient widths. The use of the trench, even though almost universal, is by no means absolutely necessary. It is a labour-saving and a moisture-conserving expedient, that is all, though it must be admitted that it is easier to water the plants in trenches than on level ground. Trenches also facilitate the operation of earthing up. Having prepared the trench by digging out the earth, and virtually doubling its depth by the simple process of forming a ridge on either side with the excavated earth, and having also richly manured the bottom, the Celery plants must be carefully removed and planted in it at distances of 9 inches, 1 foot, 18 inches, or 2 feet apart, according to the size of the varieties, the season of the year, and other considerations. The removal of the plants from the nursery bed to the growing trench is the most important step in the whole operation of Celery cultivation. The object is to transplant without giving the plants the slightest check. Each check means the risk of bolting as well as a loss of quality. Begin at the outside of the nursery bed, and move each plant with 4 or 6 inches of roots and manure intact, and place it in the trenches a trifle deeper than it was before. Before doing so, however, look round the plant and remove any suckers from its base with a sharp pointed knife. The plants should be pulled out with a small fork or the fingers. Each piece of manure will then be furnished with roots running out from its ragged edges in all directions. If these pieces are carefully planted, and the projecting roots pointed into the manure in the trenches and the plants are well watered, they will receive no check. It is well, however, if possible, to choose a dull or a showery time for the final planting out of Celery; and should dry weather ensue, frequent sprinklings and a slight shade with a few boughs will be useful. On no account must the plants be allowed to flag. From this time watering, weeding, and the careful removal of suckers will be all that are required until within a month or six weeks of the time when the Celery is wanted for use, when it will require to be blanched. Preliminary to this all suckers should be removed, and the plants might be loosely tied up with thick strands of matting. It is also good practice to top-dress at this stage with a little guano, or rotten manure, or several soakings of house-sewage, manure-water, or even clean soft water. It is of much importance that the roots should not be dry, for they will receive no more water for the season after being earthed up. Neither, however, must the opposite extreme be indulged in—nor should Celery be earthed up for a day or two after a copious watering. It greatly facilitates the process of earthing up to shave down the earth from off the sides of the ridges, and if three men can be spared for the operation, it then becomes a simple matter. One should stand over the plants and pack the fine earth firmly round them as he holds them closely together with his other hand, another at either side cuts down the earth and breaks it fine. Of course one man can manage it all, but it is

much more tedious and slow. The great point is to keep the plant straight and firm, so as not to allow the earth to enter into its heart, nor get between the leaves. The entire plant may be earthed up from its base to within 6 inches of the end of its longest leaves. It is necessary to leave these leaves out to preserve the plant in health, and to prevent it rotting off from the sudden shock to its system. In a month or five or six weeks the Celery will be blanched white and be ready for use. Celery requires some careful management in taking it up and preparing it for table. Begin at one end of the trench, and dig the plants out in succession. Seize them firmly by about the middle of the stalk, remove all the outer leaves, cut off the roots in a slanting direction, and if for cheese or salad draw off the leaves close till all that is left is white as crystal, reserving, however, the best of the rejected leaves for soup. For kitchen purposes a much rougher dressing suffices. If it is desirable to keep Celery for many hours out of the ground it must by no means be dressed close or washed until wanted, as Celery soon loses its nutty flavour, when exposed in a bare state to the air. In winter, however, or in bad weather a week's supply of Celery may safely be taken up at one time and kept in a rough undressed state, stored in earth or sand. Successive crops should be all treated in the same way, with the exception of the winter and spring Celery, which is to be managed as already indicated. As to varieties of Celery almost every one has his favourite sort, and they are numerous. If Seymour's Superb Solid White and Red can be had they are still perhaps as good as any, Cole's White Perfection, Sandringham White, Veitch's Incomparable White, Matchless White, Hooley's Conqueror, Prize Red, Leicester Red, Harrison's (solid, crisp, and fine flavoured), Lang's Mammoth (one of the finest large varieties). But quality in Celery is far more a matter of culture than of sort. Liberal preparation and rapid growth without check or hindrance from seed-bed to cheese plate or salad bowl, are the chief points to bear in mind in the culture of first-rate Celery. D. T. FISHER.

FARMYARD MANURE.

Discussing the subject of manures and composts, more with regard to their general use and procurableness in gardens than to their order, I cannot possibly pass over the above. Horse manure, though stronger than cow manure, is not so generally useful. For digging in among or mulching out-door crops it is excellent, but for pot plants it is not adapted either in a fresh or spent state, being rather light and a breeder of worms. In Melon or Cucumber beds worms increase at a prodigious rate, and become positively injurious; we have long discontinued using it for such purposes. It is a good manure for mixing in Vine soils, but when employed in newly-prepared turfy borders in any quantity, we have known it produce unexpected results by causing violent fermentation, which lasted for months. When it has to be used in this way, or for composts, it should be previously mixed with the soil, and allowed to lie for some time. As it comes from the stable yard, it is often in dry, crusty, flakes, which should be thoroughly teased out before it is added. Its texture fits it for heavy soils, which will absorb a large quantity of it with advantage, if applied periodically; but we do not care to use it for potting composts, let the loam be ever so heavy, so long as we can get leaf-mould or peat and sand as lighteners, and any other manure. Cow manure, if less rich than that of the horse, is more lasting, and, being a cold manure, it is one of the best for light, dry soils; for Vine or Peach borders that have become partially exhausted hardly anything better can be recommended as a dressing. We could furnish instances of Vines bearing heavy and excellent crops annually for twenty years or more, the result of periodical applications of cow-dung, sometimes mixed with soil. The manure was applied fresh, being dug into the border. Some of the largest Peaches we ever saw were from trees that had been treated in a similar manner. Of course, cow manure may be applied with great advantage to mostly all garden crops, when it is procurable for such purposes; but in the garden it is usually reserved for select subjects and for pot-plants. It cannot be used fresh for the latter, but should always be laid up in a heap until it becomes black and rotten, but not too much so; it is generally fit for use when its greenness has disappeared. That which is collected from the fields is the best for horticultural purposes, being pure and free from litter. As a rule, it can be got in this form for the gathering, and a store should be laid in once a year. When rotten, it loses its tenacity and breaks up as fine as peat, in which condition only it should be used for potting.

To such things as Camellias, and mostly all stove and greenhouse plants, that thrive in a mixed compost of loam and peat or leaf mould, it is acceptable in greater or less quantity, according to the habit of the plant. Liquid cow manure we do not esteem very highly, and we say so, knowing that it is often applied in this way. But the manure alone is better used in a solid state, as its value depends almost as much upon its coolness and moisture-retaining qualities as its feeding properties. J. S.

Failure of Winter Spinach.—On retentive soils the failure of Winter Spinach seems to be general this season owing to the increased rainfall. Our earliest sown bed for autumn gathering has nearly all disappeared, but the later sown crop on a south border with a considerable inclination to the sun is in good condition. A warm dry site for at least a portion of this crop is in some places a necessity. If it were not so, there is a considerable advantage in the early growth, which a warm site ensures. In the spring, when Spinach begins to bolt or run up for seed, in gathering it for use, instead of picking off the leaves in the usual way, I find it more profitable to cut off stalks and all together, picking the leaves from the stalks afterwards. When thus treated, a new and luxuriant growth starts up quickly from the crown of the roots with a less disposition to seed, and the produce is increased immensely. This treatment has more conspicuous effect upon later sown crops than such as are sown in July for autumn use.—E. H.

Soot.—We once heard an intelligent Middlethorpe farmer remark that the time would come when the sweeps would be glad to sweep our chimneys for the privilege of getting the soot. At present it is one of those manures which is not sufficiently appreciated. It can generally be procured in considerable quantities about houses where the chimneys are swept periodically. On such occasions it should be collected at once, and stored in old barrels or boxes, and put under cover. Soot is a safe manure for garden purposes, and yet powerful in its effects upon some crops, such as Onions, Grass, Potatoes, and root crops generally. Mixed with about a tenth of its bulk of common salt, it acts still more decidedly, and is more powerful than many dressings of farmyard manure. To pot plants it should always be given in the form of liquid manure. We have applied it in this way to almost all kinds of pot plants with the best results, always keeping a little diluted in the tanks, so that the plants get it in a weak state every time they are watered. For such purposes it certainly is a cheap stimulant, and perfectly inoffensive as regards smell. For Carrots and Turnips there is hardly anything better. Scattered liberally over the plants when just coming up, and afterwards washed in with water; it hurries them into rough leaf, and they so escape the fly. Applied to Grass lawns it improves the sward in a very short time; it should be put on in wet weather.—J. S.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Mushroom Growing and Sawdust.—Will some of your readers kindly say if sawdust used as bedding in stables and mixed with horse droppings is prejudicial or the reverse to the growth of Mushrooms.—R. E.

Porcing Mint.—Green Mint may be easily obtained now by placing a handful of roots under an inch or two of soil in the corner of a hot-bed or in a cutting box covered and watered, and put in a house where the temperature is about 60°.—M.

Good Winter Spinach in Undug Ground.—For seven years past I have always had abundance of good Spinach. My plan is to sow it the first week in August when the early Peas come off the ground. The secret in growing Broccoli—in fact, all the Brassica tribe—is to plant in good firm land without its being dug. The Peas stakes being removed, we give the land a good hoeing and raking, draw the drills 1 foot apart, and sow the seed, treading it in; I slightly level the land with a rake afterwards.—R. G.

Coleworts in Private Gardens.—Mr. Dean wonders why gardeners do not grow these useful Greens. I think he will find that they are grown largely in private gardens. I grow half an acre of them, and find that nothing is better in the way of vegetables than good Coleworts. I am rather puzzled to hear that Peas follow Coleworts, when, as a rule, market gardeners do not grow Peas at all. Mr. Steel, a near neighbour of Mr. Dean's, is one of the very best market gardeners—perhaps he will tell us. I dare say the Editor of THE GARDEN would not object to market growers becoming writers too. If so, we should learn a good many things.—R. GIBSON, *Sturghley*.

Soot as a Manure.—Anyone using this as a manure must be careful how they apply it. Although highly beneficial to established crops in a mild or diluted form, it is of too burning a nature if applied in a raw state and in large quantities to young tender crops. I have seen rows of Peas and Beans heavily dressed with soot to keep off rats and mice, which so weakened the young plants that they never overcame the evil effects of the soot. I consider lime and soot require great care in application, or more harm than good may result.—J. GROOM.

How to Cook Broccoli or Cauliflower.—To have really good Cauliflower, large quantities of manure in some shape are requisite, so much so that they become "strong" in flavour. To obviate this, they should be parboiled in the morning of the day when wanted. When parboiled, place them on a hair sieve and put them in the larder; 20 minutes before they are wanted for table, re-boil them steadily, and the strong taste will be gone.—R. G.

TOWN GARDENING.

The city gardener has to learn what to grow and what not to grow, what will thrive with him and what will not; and, therefore, he has to be more than careful in his attention to the wants of his pets, or they bid him a sad adieu. The country gardener, on the contrary, with ordinary care, can induce most plants from a temperate climate to grow in perfection. The city cultivator, especially if he takes to amateur gardening, has to fall back upon the broad-leaved and lusty Pelargonium, the Fuchsia, the Wallflower, the Ten-week Stock, and the Mignonette, among flowers; and the Acucuba, the Lawson Cypress, the Sweet Bay, the Laurustinus, the small-leaved Arbutus, among ornamental evergreen plants. True, he can manage bulbs of most sorts, such as the Hyacinth, the Tulip, the Crocus, the Snow-drop, and the Squill; but he has to struggle hard to keep up anything like an effective display. And can we wonder at it when we see multitudes of chimneys that, notwithstanding sanitary regulations, still belch out black smoke. When one gets into the suburbs, conditions improve a little; and it would be well to join together, in a co-operative way, in order to secure a bit of ground in the outside of smoky towns, where oneself and family could cultivate in perfection a few flowers in summer, and, it may be, a small kitchen garden. Therefore, let us see how this is to be effected. A garden frame will of course, be in request to nurse tender plants and seedlings from the cold blasts of March and April, and even May; but a glass protection alone is not sufficient for that purpose. For the raising of artificial heat, fermenting material is generally employed; it may be manure from the stable, or it may be leaves, or Fern, or any other matter capable of generating heat. Stable manure is best, and of that several cartloads must be obtained, to supply one of the fundamental needs of flower gardening. But, to return to town gardening; notwithstanding its acknowledged disadvantages and difficulties, the man determined to succeed may produce, not only green crops, but flowers, even in a north aspect, and under the very shadow of a gasometer. The problem is how to grow flowers in a soil of cinders and an atmosphere of smoke—flowers which, of all things, revel in sunshine, and demand it as their right. Town gardening, as at present practised, is indeed a sorry affair. Neither the scientific gardener nor the enthusiastic lover of natural beauty carries his garden with him to the town when necessity compels him to live amid smoke. Neither of them dream that city life might be vastly improved if a few flowers were associated with it. Yet the love of flowers seldom wholly dies out. In the dusty courts and alleys, Wallflowers, Stocks, and Musk plants are purchased every spring, and planted, some in boxes and some in the proverbial spoutless tea-pot, in mould in which nothing can possibly thrive. Geraniums pass a torpid winter life, under such conditions, on window-sills and in dark parlours. In summer they put forth a few shoots of every tint but green, and sometimes a blossom or two, but, after a brave attempt to grow and flourish, they become affected by root-sickness, get leafless, and often die. Thousands of beautiful plants are every spring and summer brought from the nurseries round London and sold in the city to undergo an existence similar to that just described, their demise being accelerated by copious supplies of water at improper times, and none at others when really needed. In the suburbs, matters, as I have already said, improve. For shop fronts we get green iron railings, enclosing small plots of garden ground. Here, overgrown Box borderings give shelter to sooty patches of London Pride, Heart's-ease, and Nasturtiums, that rival Pumpkins in size and rankness. In spring, we have a few clumps of Primroses and Polyanthus; and when these are gone, they are succeeded by Wallflowers, early Stocks, Sweet Williams, and double Daisies, all of which are usually purchased of some itinerant florist, who supplies them at various prices, ranging from one to ten a penny. Forthwith, the garden breaks, as it were, suddenly into bloom. But, alas! its duration is but short. Towards midsummer, a few Geraniums may be seen, arrayed in bright scarlet; and, with these, are perhaps intermingled a few Verbenas and a blue Iris, some Marigolds, Love-lies-bleeding, Chrysanthemums, and Hollyhocks, all more or less blighted by smoke or ill-treatment; dingy Hollies, too, rise out of pyramids of stones; stiff Laurels look as if they were cast in bronze, and have scarcely grown an inch since they were planted; dilapidated Lilacs form Arcadian retreats for cats and slugs; Lime trees are every year cut so as to look like square boxes set on pedestals; and occasionally one finds on the walls a Virginian Creeper, the Ivy green, and a straggling Jasmine. These constitute the chief contents of front gardens, each of which would be a Pestum, were it not that the Roses, hitherto unmentioned, never blossom. Nevertheless, all this might be improved, provided right means were adopted, and that, too, without exorbitant toil, or great expense. It is, indeed, one of the peculiarities of gardening that one may spend upon it just as much as one can afford, and no more, and yet have a satisfactory result.

Meadowbank.

JAMES ANDERSON.

Root-work v. Rock-work.—Your correspondent, "W. S." (see p. 543, Vol. VIII.), objects to root-work as being entirely unsuited to either Alpines or hardy Ferns. I do not think that either root-work or rock-work is absolutely essential to a garden, but I fail to see why plants that flourish in rock-gardens, should not grow equally well on properly constructed root-work. As regards hardy Ferns, I have seen clumps of Hart's-tongue quite a yard in diameter, growing by "natural selection" on old Moss and Lichen-covered tree stumps that have stood for an indefinite period in hedgerows; clumps, such as these, removed, stumps and all, to our Fernery, gave it quite a furnished and finished appearance at once, which it still retains. I cannot agree with "W. S.'s" remark that root-work should never be used except for the formation of screens to be quickly covered with climbing plants. Such hard and fast rules, without exceptions, would destroy that greatest charm of our gardens—individuality. On some of the principal points in the formation of gardens all of us are pretty well agreed, but minor details should, I think, always be left to be worked out in harmony with the surroundings of each individual place, whether it be large or small. No two gardens should reflect each other's features, as in a mirror.—J. GROOM, *Henham*.

Heated Plant Cases.—Allow me to thank Mr. Boyle (see p. 531, Vol. VIII.) for his suggestions in reference to the heating of plant cases, and to express my satisfaction that he agrees with me in condemning an exclusive application of bottom-heat. I am entirely of his opinion that ventilation is a most important question in a heated case, but I believe I have provided for a sufficient circulation of air in the arrangement which I propose to adopt. The statement in my former letter that I desired to grow stove Ferns, and perhaps other plants requiring similar treatment, appears to have led Mr. Boyle to believe that I intended placing stove and greenhouse plants together, but this, I need scarcely say, was not my meaning. My idea is to have a miniature stove with a group of plants thriving under the same conditions of temperature and moisture, a plan by which I hope to be successful.—PHILO-FLOS.

Red Lead an Effectual Protection against Birds.—No bird, rat, or mouse, will eat any vegetable substance that is well coated with red lead. I have used it for many years for all kinds of seeds that birds attack, just damping the seeds, and then stirring a little of the lead amongst them till they were quite red, and I never saw either a bird or vermin meddle with them; whereas, without it, we cannot get such things as seeds of the Brassica tribe and other vegetables through the ground; consequently its use is reduced to a system here. For Gooseberry, Currants, and fruit tree buds it is equally effective, but I find I cannot apply it through a syringe, so as to coat the buds thick enough to keep the birds off, in which way I tried it some years ago. To apply it to our bushes and trees with a brush takes more time than we can afford, and would not, I think, pay for the fruit saved. I may add that the late Mr. Robert Fish recommended its use nearly twenty years ago.—J. S. W.

Preserving Walnuts.—The complaint of your correspondent (see p. 556, Vol. VIII.), respecting the difficulty of keeping Walnuts through the winter, reminds me of two plans which I have been assured are equally efficacious—one is the Belgian or Dutch plan of never taking off the green outside until the Walnuts are required to be eaten; it is said that if laid on a dry board and turned when necessary, they will keep perfectly fresh, although the green husk will by degrees turn black. The other plan was mentioned by a lady, whose attention had been turned to the fact that if Nuts or Walnuts, laid up by the squirrels, had been forgotten—as is not unfrequently the case when those little animals have an abundant harvest, and forget to revisit all their store-houses—their Nuts are found in spring and summer to be as fresh in hollow trees and Mossy corners, where they are deposited, as on the day when they were gathered. This lady tried the experiment of putting her Walnuts out of doors, exposed to damp, though not immersed in water, and the result was her never failing to have fresh Walnuts throughout the winter.—A. LL.

Timber and the Rights of Life-Tenants.—The "Law Journal" contains an elaborate report of the case of *Honywood v. Honynwood*, which is most valuable as containing a full exposition of the law with regard to timber, delivered by the Master of the Rolls. First, then, what is timber? This is a question which must be answered partly with reference to the general law of England and partly with reference to the special customs of various localities. The general law of England is, that Oak, Ash, and Elm, are timber provided they are of the age of twenty years and upwards, and provided they are old enough to have a reasonable quantity of usable wood in them, or, as the text writers say, sufficient to make a good post. Now, then, as to the special customs of particular localities. Some trees which are not timber by the general law of England are timber by the custom of a particular county or locality. Beech is timber in

some counties, Hornbeam is timber in others, and in some localities Whitethorn and Blackthorn are regarded as timber. In some localities the age when a tree is to be considered as timber differs from the twenty years fixed by the general law of England. In some places the age of twenty-four years is fixed as the proper age; in others age is disregarded, and the test is the girth of the tree. What are the rights of the tenant for life, with regard to the trees on his estate? If he be impeachable of waste (as the legal phrase is), he may not cut any timber, unless, indeed, the estate be a timber estate—i.e., "an estate which is cultivated merely for the produce of saleable timber, and where the timber is cut periodically." Then the timber is regarded simply as the crop of the estate, and therefore as a matter of course, goes to the tenant for life. Now, then, what may our tenant for life, impeachable of waste, cut? The answer is this:—He may cut all that is not timber, with the following exceptions—ornamental trees, stools of underwood, trees planted for the protection of banks, and trees which, though not already timber, only want time to become timber. These latter, i.e., young trees of the nature of timber, he may cut, if they be cut in the due course of the management of the estate for the purpose of allowing the growth and development of other timber in the same wood or plantation. This, as the Master of the Rolls said, is for the improvement of the estate, not the destruction of it, and therefore cannot be regarded as waste.

The Royal Vineyard Grape.—I see that Mr. Crambe (page 538, Vol. VIII.) recommends the White Lady Downes late Grape as an excellent keeping variety for a cool Vinery. I wish to notice another rather unpopular late white Grape for a cool-house, namely, the Royal Vineyard. With me it hangs unshrivelled into April and May, and, although hard fleshed, as all very late Grapes are, its flavour is very good, and, from its fine amber colour, it makes a good contrast in the dessert with the Black Lady Downes. The Muscat and Trebbiano are higher flavoured varieties, but they want a warmer temperature and longer time to ripen well, and they do not keep so long without shrivelling.—WILLIAM TILLEY, Welbeck Abbey.

Ornamental Grasses (p. 539, Vol. VIII.)—It is not often that any of us can add to Mr. Niven's excellent notices of flowers, but he has made no mention of two Grasses which I rank among the most ornamental. These are *Gymnoxith latifolia* and *Andropogon halensis*. They are both quite hardy, but in both of them the beauty is more in the foliage than the flowers, which may account for their omission in Mr. Niven's list. The *Gymnoxith* is a grand Grass, with wide, deep green leaves, and a compact habit. Here it grows over 6 feet in height. The *Andropogon* is of a looser habit, with long, narrow, leaves, each with a white stripe in the middle. I am surprised at hearing that *Pennisetum longistylum* is too tender for our winter. Here it is quite hardy, and is one of the best of the low Grasses. Mr. Niven does not remember ever seeing any record of the blooming of *Arundo Donax*. He will find it thus recorded in the "Hortus Collinsonianus":—"Arundo Donax in flower, September 15, 1762, the first time I ever saw it; but this very long, hot, dry, summer has made many exotic flowers. . . . It bears a handsome tassel of flowers."—HENRY N. ELLACOMBE, *Bilton Vicarage*.

The Pheytumas.—The Pheytumas are the glory of Switzerland. The rarer species are chiefly scattered over the Tyrol and the Grisons. During my many visits to Switzerland, I have gathered nearly all the Pheytumas, and seen them growing in their own wild homes. During a recent visit to the Val de Fain, among the Bernina Mountains, I met with a strange form of *P. humile*, with long grassy leaves and bracts overtopping the heads of flowers. These bracts were rigid and finely denticulate. Moreover, they were furnished with purple processes at the base. Sieber, from his grassy foliage, named it *graminifolium*. Koch speaks of this very variety in the Val de Fain as *P. humile purpureum*, in consequence of the purple processes at the base of the bracts. This species and its variety grow side by side, wedged in the crevices of the calcareous rocks, high up the mountains. This species was in full blue flower—the variety in backward bud. I gathered fully half a dozen plants of the grassy long leaved variety. The true *P. humile* was not uncommon. I have gathered *P. humile* in various parts of Switzerland, and also *P. pacificum*, but the long-leaved variety only in the Val de Fain.—PETER INGHALD, *Hovingham Lodge, York*.

Do Christmas Roses Seed (see p. 535, Vol. VIII.)—It appears that Mr. Ellacombe is of opinion that the Christmas Rose can re-produce itself from seed—a fact concerning which Miss Hope replies that Bilton is an exceptional place, and that is true, as all must admit, who have been fortunate enough to visit it; but certainly not as regards the seeding of the Christmas Rose. It is now ten years since I purchased three plants of *H. niger*, and at the end of two seasons one of these had grown so large that I determined to cut it up, which division gave me twenty-five plants. This was done

just before the young leaves made their appearance, or at the end of the blooming season, which is by far the best time to divide Hellebores, as if well looked after for a short time they soon grow on, and do not remain dormant for an indefinite period. These twenty-five plants were put into a bed in the kitchen garden, and at the end of two years I observed in one corner a batch of seedlings which appeared to be small Hellebores, but to make certain I allowed them to grow on until the autumn, by which time they had attained the height of 6 inches, when no doubt could be entertained about their being seedlings from the Christmas Rose. I am therefore convinced that in some seasons, under certain conditions, not at present perhaps accurately known, this plant does seed, although apparently the fact is still a matter of doubt with many. I now much regret that I did not bloom these seedlings, as probably they would have shown some variations from the original, and consequently might have been valuable. I have tried to seed *H. maximus*, at present without success, but two years since I used its pollen to hybridise *H. colchicum*, and from this I have a small batch of seedlings, which, judging by the foliage, show that the cross has been effectual.—BEKKS.

An American Fruit Car.—A fruit car is being built at San Francisco, says the "Boston Advertiser," for the transportation of fruit from that city to Chicago. It is provided with a fan-blower, driven by one of the car-axes, by means of which the air is driven through ice, which reduces it to a low temperature, and then distributes it among the fruit boxes through a large perforated pipe laid along the bottom of the car. After the cool air has passed among the fruit it returns to the blower, and is again forced through the apparatus. By this means the atmosphere of the car is kept at the uniform temperature of 40° Fahr. If the experiment succeeds, extensive shipments of Grapes and other fruits will be made to Chicago and other cities.

NOTES AND QUESTIONS—VARIOUS.

Schizostylis coccinea in Derbyshire.—This pretty border plant was in bloom out of doors in Derbyshire during the snow, and is still flowering freely. *Crocus serotinus* was also in bloom amid the snow.—M. S. L.

Drying Leaves.—I am about to make a collection of leaves of different plants. Can you inform me what is the best way to dry them, so as to retain, as nearly as possible, their natural colours and forms?—HEBERT. [Good instructions for drying both leaves and flowers will be found at page 196 of the second volume of THE GARDEN, and also page 242 of the same.]

The Flavour of Fruit.—There can be no doubt, and a trial will prove it, that the flavour of fruit is much more delicate under a warm temperature than a cold one. Claret and Madeira should be milk warm or nearly so, to bring out their delicate flavour and bouquet. So with fruit; but we generally want fruit cooling to the palate. No one, for instance, would prefer a fresh Melon warm from the frame to one cooled down and refreshing.—W. N.

Physianthus albens.—In the account of the gardens at Batsle Abbey (see p. 546, Vol. VIII.) this plant is mentioned as fruiting well out of doors. Here it fruited under similar circumstances some years ago, and an account of it, with a figure of its singular fruit, was given in the "Gardener's Chronicle," December 16th, 1865. This particular plant has since been killed by frost, but we have again some plants of it growing out-of-doors.—D. URSELL, *Morston, Dorchester*.

Fruit Trees on North Walls.—In addition to the fruits enumerated as suitable for north walls by Mr. Saul (p. 538, Vol. VIII.), allow me to add that many of the best of the early ripening autumn Pears are grown here on that aspect, and generally do well. Amongst these are Jargonelle, Williams's Bon Chrétien, Thompson's, Louise Bonne of Jersey, Fondante d'Automne, Marie Louise, and others. The last named is better here from a north wall than any other aspect. That fine Pear, *Pidmeum Duchesse*, would undoubtedly do well in such a situation.—W. COX, *Madrasfield Court*.

Zonal Pelargonium in Winter.—No one ever wrote an article with more truth in it than that by Dr. Denry on Zonal Pelargoniums flowering in winter. Here now we have them full of brilliant flowers, and fine bold trusses in many colours. The simplicity of their culture makes them all the more valuable. Struck in small pots in July, shifted into 48-sized pots when rooted, and kept in a succession Fine-stove at a temperature of from 55° to 60°, they thrive and flower perfectly.—R. GILBERT, *Burghley*.

The Moon Creeper.—The chief recommendation belonging to this flower is its perfume, which is the sweetest and most delicate of any with which I am acquainted. Some nine or ten years ago, Mr. Vain used to cultivate this plant at Langstein; and most probably does so still. The only one there, was to cut a single bloom, about 8 or 9 o'clock in the evening, and place it in a glass of water in the drawing-room, which was soon filled with the most delicate perfume.—H. ELLIOTT.

Tom Pnt Apple.—At p. 638, Vol. VIII., Mr. Scott informs us that this excellent Apple was raised by a Somersetshire clergyman of that name. It would be interesting to know at what date it made its appearance. There is a tree here bearing that name, which I think is the one Mr. Scott describes. This tree cannot be less than fifty years old and probably much more; nevertheless it bears regularly good crops of fruit, and it is certainly remarkable that so excellent an Apple should not have become better known than it is.—D. URSELL, *Morston, Dorchester*.

It is said that this Apple seems to be very little known, but in these parts it is very common, and few orchards are without it. Its special value is as an early kitchen Apple, following the Codlins. It is also a good cider Apple, but it is not a good keeper.—HENRY N. ELLACOMBE, *Bilton Vicarage*.

London Churchyard Gardens.—In the remarks on planting these (see p. 643, Vol. VII.) it was indicated that the plants were to be planted in winter, thriving remarkably well in London, whereas Yews share the fate of all other evergreens.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

STORAGE AND SPRING PROPAGATION OF BEDDING PLANTS.

The constitution and habit of bedding plants differ so much, even among varieties of the same species, that, to be successful in keeping them through the winter and propagating them in spring without losing an undue per-centage requires some care and not a little experience. Hence the losses one so frequently hears of among anxious stock-holders, and hence, also, the immense trade still done by nurserymen, even in the commoner kinds of bedding plants, as, for instance, some kinds of Pelargoniums, Calceolarias, and especially Verbenas, of which some make a speciality, propagating them successfully in thousands every spring, and sending them by post to customers. The winter storage of the plants, whether young or old, or whether they are kept for furnishing cuttings or for planting, is an important matter. Pelargoniums being the staple article for furnishing beds deserve notice first. Like Grapes, they are more or less apt to go off by damping, according to the soil and locality, or according to age and variety—that is, supposing them to be wintered in the usual cool pits or houses, with just a little heat to keep out frost or excessive damp. Autumn-struck cuttings keep better than old plants that have been lifted late in the year and potted; but everything depends on the way the latter are managed. We find, always, that lifted Pelargoniums of any kind are most apt to die off when they are cut down at potting time; or if they have their branches shortened by the knife, unless nursed attentively for awhile, they are sure to die back from the cut parts; the only way to save them, when so treated, is to keep them growing for awhile in a brisk heat. The best plan, however, is not to shorten the shoots at all, but only to thin them out, leaving those that are left entire. This makes long-legged plants in spring; but, in bedding-out, they can be pegged down, and they come in early—even a long time before planting out—and afford plenty of cut flowers. They also yield splendid cuttings in March and April. Those of the Tom Thumb section resist cold and damp best; while variegated sorts, and, notably, kinds like Flower of the Day, Alma, Golden Chain, and the tricolors, suffer soonest. The destructive agents are always cold and damp; and, notwithstanding attention to ventilation, and picking off decayed leaves, the shoots will continue to die back, if the temperature is low—say under 45° or 48° for any length of time together,—simply because the vitality gets low; and nothing checks decay sooner, or more effectually, than a rise of temperature, just sufficient to excite growth. If the plants have been touched with frost before lifting, they are more difficult to keep than if they had been cut down to stumps. A very sensitive yellow Zonal variety, named Beauty, which is an excellent bedding kind, but a difficult plant to winter successfully, would have been entirely lost to us this season, had the plants not been forced to break afresh when potted late in November. As it was, all shoots died back till they were met by the returning vitality, when decay was arrested just where the buds broke first. It is a kind we prefer to propagate in spring. In kinds having coloured leaves good foliage is everything, as we find spring-struck cuttings grow most luxuriantly and flower the least. We have seen enquiries lately as to the propriety of storing Pelargoniums in cellars during the winter. This we have seen tried on a large scale, and can state, that though a percentage will be saved, many will perish. When this plan is adopted, lifting the plants should be deferred till the last moment, but they should not get touched by frost, nor must their shoots be shortened. They should, after being cleaned, be set upright with their roots in dry soil, or they may be potted and set closely together, and they should not be watered during the winter, there being little or no demand upon the roots for moisture, the only object being to keep the plants alive till spring. Once or twice during the winter they should be gone over and have the decayed foliage picked off, and by

February, if practicable, the plants should be removed, potted, and started in a gentle heat. Most likely the shoots of those which survive will be much shrivelled, but they will soon recover under the influence of heat and light. It is not essential that the cellar should be light, but it should be dry. Cellaring is a plan not to be recommended, however, with Pelargoniums when the preservation of the plants is of importance. It is much better to lay the plants in by the heels in spare corners or shelves in the Vineries or Peach-houses, or other cool structures, where the chances of keeping them are much greater. The wintering of miscellaneous bedding stock depends upon the habits of the different subjects; Ageratums, Verbenas, Centaureas, Gazanias, Heliotropes, Petunias, Salvias, Alyssums, Lobelias, and plants of a similar description, if rooted and established at the proper time in autumn, will remain healthy and vigorous in a still dry atmosphere of 40° or 45°, if they are not shaded or kept too far from the light. None of these plants should be encouraged to grow in the least until about three weeks or a month before cuttings are wanted from them, and, as it is not desirable to propagate such stock till about the beginning of March, their growth need not be pushed till February. Plants which have been well rested during winter always yield the best cuttings, and the young tops never fail to strike freely with ordinary care, whereas plants that have been kept moving in a sickly atmosphere during the winter produce very uncertain results. Fuchsias potted and not watered will keep in a dry shed or cellar as well as most plants till they have to be started in spring. Alternantheras, Amarantus, Iresine, Coleus, Tropaeolums, and all the tenderer kinds of summer bedders require comfortable quarters in winter, or they will lose their foliage and otherwise suffer. Coleus, Iresine, and Tropaeolum are particularly sensitive, especially the last-named, which will almost to a certainty go off if wintered in a cool house. It should be kept dry at the root, and just moving as regards growth. A dry warm shelf near the light ends is best. Calceolarias should, of course, never feel fire heat. Cuttings dibbled in early in November, in a shallow light frame, never fail to strike, and seldom damp off if they are not shifted too much in mild weather. They cannot stand both darkness and damp; but, when hard frozen, they will remain covered up with litter for a month or more without danger. This we have proved over and over again. When the temperature rises again, it is only necessary to thaw the plants before uncovering them; and this is done by watering them with cold water from the open tank; as soon as the leaves feel soft, and the soil about the roots seems quite thawed, they should be uncovered. We have often heard of serious losses through the plants being exposed to sunshine, while still frozen; and we once lost a quantity through an inexperienced workman thawing them with water from a hot-house tank. In a frame of Calceolaria cuttings here, which are dibbled in so thickly as to touch each other, and which have passed through irregular and severe weather up till this date, we do not observe a single decayed leaf. Slips of Violas, put in during autumn, may be treated like Calceolarias; but they are hardy enough, and are benefited by nothing so much as light and free ventilation. Hollyhocks and Carnations only require protection from severe frosts and damp, and are often covered with wooden shutters, which are removed or tilted up daily, according to the weather. Succulents of the Echeveria class and other bedding kinds, not hardy, require a dry temperature of 45° and little or no water at the roots. E. secunda glauca sometimes stands the winter out-doors in dry situations, but it is very unsafe to trust stock of it out of doors after November. We always take the plants up and set them thickly together on a dry tank behind a north wall, and lay a few old lights over them in severe weather, and sometimes a little straw. As regards propagation, all bedding plants may be increased most freely in spring, or between February and May, by means of cuttings. It is desirable, however, to propagate some kinds in autumn—Pelargoniums, for instance, that are wanted to flower freely—as spring-struck plants grow too luxuriantly; but those which are grown for their foliage may with advantage be struck in quantities in spring. Indeed, where the general stock is small, it may be recruited easily up till the time of planting out. Gazania splendens is a plant which is much better propagated in

autumn, and merely potted off in spring, as plants struck later than the beginning of February are late in flowering, and to take the tops off autumn-struck stock at that time is effecting a useless exchange. Lobelias, for bedding purposes, are very commonly raised from seed, but seedlings are irregular in their habit and colour, and far inferior to plants from cuttings. A few old plants of the best habited seedlings lifted, partially cut down, potted in August, and kept in a cool house during the winter, will yield fine cuttings in March, and every shoot will strike freely in the hot-bed; after that they should be hardened off and pricked out in a cool frame, from which they will lift well with good balls at planting time. Verbena cuttings, if furnished with healthy foliage, strike with marvellous rapidity and freedom in spring, and every piece with a leaf attached will make a plant. Other bedding plants already named also all strike most freely; and one thing, which is not generally known, is, that the latest struck plants generally grow best after being planted out. For this reason gardeners generally try to secure a good quantity of healthy stock plants, so as to have one or two good batches of cuttings only, which they seldom take off till March and April. We frequently find that the last plants which are just transferred to the beds from the cutting-pots grow away most freely. The great point in striking cuttings, and in nursing the plants afterwards when they are potted or boxed off, is to avoid codding. A bottom-heat of 75° or 80° and a top-heat of from 65° minimum to 80° maximum should never be exceeded in the cutting-pit, and when transplanted and placed in the store-frames an atmospheric temperature 5° lower than the above will be suitable—always keeping it genial by judicious ventilation and watering. Lobelias from seed should never be sown later than the 1st of February, nor subjected to a temperature higher than from 60° to 75°, night and day, till they are pricked out. Verbena venosa should be sown at the same time and treated in the same way. The *Humea elegans* must be sown early in the autumn previous to being planted out and potted on; and so also should the *Centaureas*, but we have had good beds of these from plants sown at the same time as Lobelias. In the above remarks I have spoken of the commonest bedding plants chiefly, and such as most people grow and want to know most about. Of sub-tropical plants we may speak hereafter. J. S.

Ixoras and their Culture.—Will Mr. Baines kindly name the three best Ixoras, the proper time to take cuttings of Ixoras in general, and also furnish me with a few hints as to their culture; saying whether or not they would succeed in a stove without being plunged, as I have no bed for that purpose?—H. [Several fine varieties of Ixora have come into cultivation comparatively recently, but the worst feature in connection with them is their great similarity, both as to colour of flower and general habit. The old *I. coccinea* is not only the best Ixora, but also the best stove plant in existence; yet few grow it well. *I. Williamsii*, is a fine kind and so is *I. amboynensis*, and *I. Colei* and *I. salicifolia* are both distinct, but they grow badly; consequently, I should advise "H." to obtain *I. coccinea*, *I. Williamsii*, and *I. amboynensis*. Ixoras strike readily at all times of the year when half-ripened shoots can be obtained, but early in the spring is the best time. All of them succeed best in good fibrous peat, to which has been added a moderate sprinkling of sand. To grow them well they require as much heat as any plant in existence during the spring and summer months, while in the winter they should not even at night be kept lower than 65°. Never let them get dry at the roots or allow the atmosphere to become too dry. An essential point is never to allow them to become over-run with mealy bug or scale. For these last dozen years I have never plunged either Ixoras or any other plants, although I have always had in the house a good tan bed. Where plants have top-heat enough, they are better not plunged.—T. BAINES.]

Water at the Roots of Vines.—Mr. Henry Wood, of West Chester County, has furnished us ("Moore's Rural") with an account of an interesting experiment in Grape culture, showing the importance of a dry bottom for the roots. He had a small Vineyard for a family supply, placed on the slope of a hill. The trellis extended in a horizontal direction, and the ridges formed in cultivation, as a consequence, prevented the free escape down the hill of the water from rains. The fruit was poor, imperfectly developed, badly ripened, and more or less mildewed. After some years, the trellis was altered, so as to extend directly down the slope. The furrows, in cultivation, facilitated the escape of the water from the soil, and the fruit then became well grown, plump and excellent.

NOTES OF THE WEEK.

—MR. WADE, of the Hale Farm Nurseries, sends us a noble specimen of the Christmas Rose, with some fifty large fully-expanded flowers on it, and many more in the bud stage. The flowers stand well above the foliage, forming a great white mass, surrounded by ample and graceful leaves. This, with many others like it, grew in the open air. Good flowers of the Christmas Rose have recently been selling in Covent Garden at half-a-crown a dozen.

—THE "Gartenflora," of November last, contains a coloured illustration of the double red *Rosa rugosa*, a form which has been obtained in the gardens at St. Petersburg.

—THE Myrtle-leaved Orange is now very ornamental in the Royal Exotic Nursery at Chelsea, bushy little plants of it, from 15 inches to 2 feet in height, being laden with fruit, some of the usual rich orange colour and others green. This mixture of colours, in our opinion, adds considerably to the attractiveness of this distinct and truly useful variety as a decorative plant for the greenhouse, conservatory, and even for the window of a warm sitting-room during the winter months.

—A VERY distinct and probably new *Eucharis* is now in flower in Mr. W. Bull's nursery, in the King's Road, Chelsea. Its scapes are rather more slender than those of *E. amazonica*, and the flowers are far more elegant in outline than those of that variety, the segments and tube being more slender in every way, and while they hang in clusters of from five to seven on the apex of the scapes, the segments are gently reflexed and of ivory whiteness. The leaves are broadly lance-shaped, and of a bright green colour, not broadly ovate as in *E. amazonica*.

—AMONG the most noticeable of the imported fruits brought to Covent Garden Market during the past week are some splendid samples of Smooth Cayenne Pines, perfectly fresh, ripe, and well flavoured, and varying in weight from three to seven pounds. These are in every way equal to home-grown fruit, and they can be imported and sold more cheaply than they can be grown in our comparatively cold and sunless climate. No fewer than 800 of them were sold by auction on one day last week. Shaddockes are also plentiful, some of the specimens being fully 9 inches in diameter.

—AMONG the many beautiful Orchids now in bloom in Messrs. Veitch's nursery, at Chelsea, the following are worthy of special remark:—*Masdevallia Tovarensis*, 15 inches in diameter, and furnished with twenty-eight spikes, on which there are in all seventy fully expanded flowers and buds. The flowers are of snowy whiteness, and it is difficult to imagine a more beautiful object than this plant is, especially when contrasted with some of the brighter coloured kinds. *Sophranitis grandiflora* is bearing twelve fully open flowers, each having broad petals of the most vivid orange-scarlet imaginable. A fine variety of *Pescatorea Odontoglossum*, with pure white-petalled flowers, the lip richly blotched with purple at the base and round the margin, is bearing twelve flowers. *O. Andersonianum* has a graceful spike of fourteen flowers, as has also a very fine form of *O. Hallii*. The clear yellow *Oncidium cheiroporum* is furnished with nine gracefully arching spikes, and *Barkeria Lindleyana* *Centeris* is also flowering freely, its rosy-lilac flowers being very distinct from all other kinds, and so rich and lucid as to remind one of stained glass. *Angraecum bilobum* bears a noble pendent spike of twenty pure white flowers, a number which we believe has never been exceeded. *Calanthe Veitchii* and *Laelia anceps* are also just now very attractive, as is likewise a plant of *Phalenopsis Lobbi*.

—THE directors of the Westminster Aquarium have placed the whole of the arrangements for their floral and fruit exhibitions in the hands of Mr. John Wills, of the Royal Exotic Nursery, Ouslow Square, South Kensington. Mr. Wills has to frame the schedule of prizes and arrange the shows, &c.

—THE Royal Botanic Society has published its exhibition arrangements for 1876. They are—first, an exhibition of spring flowers, on March 29th and April 26th; then an exhibition of Clematis, from Messrs. Jaekman, of Woking, from May 1st to May 23rd; after which commence the summer exhibitions of plants, on Wednesday, May 24th and June 21st. A special evening fête will take place on Wednesday, July 5th.

—THE annual meeting of the committee of the Horticultural Club was held at the club house, 3, Adelphi Terrace, on Wednesday last. Dr. Henry Bennett, of Weybridge and Mentone, Captain Chist, of Beechhurst Lodge, Westerham, and Dr. Denny, of Stoke Newington, were elected members of committee in the room of the three retiring members. It was determined to hold dissonance meetings during the winter months. The first will be held on Wednesday the 19th inst., the subject being "the principles and practice of pruning." Three new members were elected.

NEW VARIETIES OF THE PRIMROSE.

Mr. RICHARD DEAN, in a paper read at Westorham, tells us of some of the new *Primroses*. A few years ago I came into possession of a so-called species of *Primrose* known as *Primula altaica*, having all the characteristics of the common *Primrose*, but bearing large pale mauve flowers. I have reason to believe this is not a true species, but simply the old common single-lilac *Primrose* of our gardens. Almost at the same time I found in an old garden on the south-west coast of England a remarkable common single *Primrose*, having rich bright maroon-crimson flowers of fine form and a deep golden centre. I brought it home to London, propagated it, and eventually distributed it under the name of *Primula vulgaris auriculiflora*, because the flowers resembled a good Alpine *Auricula*. In this variety I found the very thing to yield high-coloured *Primroses*; but while I despaired of getting anything better in its own way, I thought I might perhaps get mauve, violet, and purple tints, which would prove very acceptable. With this view, I crossed the two above-named kinds, and got some fine seedlings, having intermediate tints, and especially in the way of purple and violet hues. Some of the seedlings were of a pale colour approaching lavender; others had rosy tints, and by crossing these in various directions I at last got a progeny, yielding to my delight, pure white and yellow flowers. I cannot do better than give a list of the new varieties of seedling *Primroses* I have put into circulation, with their descriptions:

Crimson Banner.—Very deep maroon-crimson (the darkest of all), rich golden centre.

Queen of Roses.—Pale rose-magenta, with golden centre slightly blotched with orange.

Lilacina.—Pale lilac, with yellow centre rayed with deep orange.

Queen of Violets.—Clear puce violet, with striking eye.
Rosy Morn.—A fine hue of rose-crimson flushed with magenta, orange centre.

Sulphurata.—A clear sulphur, with orange centre; flowers large, circular.

Sunrise.—Fiery red-maroon, with showy deep golden centre.
Violaacea.—Bright rose-violet, with golden centre, large, very free.

Primula vulgaris auriculiflora.—A rich maroon-crimson *primrose*, with a showy orange eye.

Mauve Queen.—Rose-mauve, with bright orange centre.
Splendour.—Large and finely-formed rose-crimson flowers, centre golden-yellow, and profuse of bloom.

Queen of Yellows.—Yellow, with deep orange centre; profuse of bloom, and very early.

I particularly recommend these for the rock-garden and the choice border, where they can be carefully tended, and be allowed to establish themselves. They can also be cultivated in pots for blooming in a cold greenhouse or conservatory during autumn and spring, as well established plants in pots will throw up flowers in autumn from the growth of the previous summer, and again in spring from the growth that takes place in February and March. The plants that flowered well in pots should be re-potted soon after they have done blooming, using a soil made up of fibrous yellow loam and leaf mould in equal parts, and some charcoal broken to the size of split Peas. At the time of re-potting, any rooted side-shoots should be taken off, in order to obtain increase of any variety. When re-potting, the long tap-root should be cut away to within an inch or so of the leaves; then plant deeply and firmly in the soil; as, when the lowermost leaves decay in the order of Nature, roots are given forth at the points where the leaves grow. This shows the importance of occasional top-dressings with rich soil. When re-potted the pots should be plunged in a bed of coal-ashes, Cocoa-nut fibre, &c., up to their rims, under a south or west wall, where they can have the sun for a few hours during the morning. Worms and slugs are apt to prove troublesome, and a little attention is required to guard against their ravages. The plants require to be kept moist during summer, and under such conditions they cannot but do well. I have several plants in pots that have been treated in this way, which are now throwing up their flowers, and are very attractive objects in my cool greenhouse. They want plenty of air on all favourable occasions; and water to keep them fairly moist about the roots.

Potting-off Cuttings.—Many plants acquire a weakly habit from being confined too long in the cutting-pots. The moment the roots have pushed from the roughly callused wound is the best time to pot, and start each plant on its separate existence. The importance of this is too often overlooked, and valuable time is lost. When the roots are long and matted together, it is impossible to disentangle them without the plants receiving a severe check. If potted off when the roots are not more than a quarter-of-an-inch long,

there will be very little disturbance of growth. The saving in time, if much potting has to be done, will be considerable. It may not be always possible to carry out this plan exactly at the right moment, but it is well to bear it in mind as the right practice.—E. HOBDAY.

Iris reticulata Forcé.—It may not be generally known that this beautiful *Iris* may be forced with the greatest ease to flower now. My practice is to lift batches of it, every second year, in July, when the tops have died down, to pick out the largest bulbs for pot culture, and to return the others to the open border, in which they are planted in fresh soil. After keeping the selected bulbs until the middle of August, I then plant five bulbs in a 48-sized pot and plunge them in ashes in a cold frame. Thus treated, by October they will have pushed about 1 inch through the soil, when they may be introduced into a temperature of from 45° to 50°, in fact, treated like a first batch of forced *Roses*. The gentle forcing to which they are subjected brings them into flower by New Year's day, and they are charming flowers for a lady's boudoir, one or two blooms being sufficient to scent a whole room with delicate perfume. This *Iris* is a great favourite here, either forced or in the open border. Its colour—rich violet, with bright yellow throat—associated with that of *Roman Hyacinths* and *Poinsettias*, has a fine effect at this season of the year. To the Rev. J. G. Nelson, of Aldborough, I am indebted for my first stock of bulbs of this *Iris*, given me eight years ago, and since then they have rapidly increased. To see his stock of this *Iris* in flower, about the last week in March, in company with a rare collection of *Crocuses* and *Dog's-tooth Violets*, is a sight too beautiful ever to be forgotten.—W. ALLAN, *Guntton Park, Norwich*.

On Raising the Clematis from Seed.—As a hardy plant now indispensable as a climber in shrubberies and for clumping, I may instance the *Clematis*, of which it is very easy to raise a large collection from seed in a short time. Last year I sowed some of the early-flowering sorts, such as *Albert Victor*, *Lady Lodesborough*, *Lord Lodesborough*, *Mrs. James Bateman*, *Miss Bateman*, *Standishii*, and *azurea grandiflora*, and, when the seed was ripe, sowed it in the autumn. None of it vegetated till this spring, for the seed is very hard and requires time to vegetate, even when in a slight bottom-heat; but the young plants have made wonderful progress this summer, and a few are now showing a bloom on them. It may be said that as plants of all the best varieties of *Clematis* can now be procured from nurserymen at a reasonable rate there is no use in trying to raise seedlings of them. There is, however, an excitement in trying to raise some new sorts of good properties, and in a large collection of seedlings this may be expected as they gradually come into bloom.—WILLIAM TILLEY, in the "Florist."

The Tom Put Apple.—This is a common Apple in this neighbourhood. One of my workmen, who has been accustomed to grafting and pruning *Apple* trees all his life, states that he recollects very old trees of *Tom Put* being in existence more than forty years ago. When exposed to the sun, it is a very high-coloured Apple; but faintly coloured when grown in the shade. Its quality as a culinary *Apple* is first rate; but I have never thought it good enough for dessert. It is in high repute here for making *Apple jelly*, which, when well made, is excellent. The tree is an extraordinary bearer; and, therefore, grows but slowly. Indeed, compared with other sorts, I have never seen a good tree of it in an orchard. The best are to be found in cottagers' gardens, where it stands alone. Its fruit sells readily in the market, and it is a good rent payer. This, *Cellini*, and *Hawthornden*, I consider to be three of the best *Apples* for small gardens.—JOHN GARLAND, *Kilberton, Wæter*.

— I AM pleased to have brought back to my recollection this *Apple*, which was a favourite of mine in my younger days, and is very common in the gardens and orchards of *Devon*, especially in the cottagers' gardens. I believe I may say that I have seen trees of it as old as any in that part of *England*, some being from seventy to eighty years old, and others even more. It is a most prolific cropper, and combines the triple qualities of an excellent cooking, eating, and cider *Apple*. The tree is a rapid grower when young, if in good soil, otherwise I have known it to remain stationary and bear prodigiously—in fact, it then produces more fruit than foliage. The tree has a spreading habit of growth; the wood is stout, and well studded with spreading bloom, generally in pairs. The one great peculiarity of the *Devon*—shire *Tom Put*, and one by which the tree may be easily identified, is the knotty protuberances on the branches, though not so prominent as on the *Welsh Burr Knot*. The fruit of *Tom Put* keeps well up to Christmas. There is another excellent *Apple* much grown in *Devon* in company with *Tom Put*, called the *Queen Apple*, which is a wonderful bearer, and the fruit is generally a little larger than the *Tom Put*. It is quite covered with a dark red skin, striped with a lighter shade of the same colour, which penetrates to the core. It is an excellent eating variety, and useful also for cooking, having the appearance of pink *Rhubarb* when served up in pies.—J. TAYLOR.

LARGE v. SMALL SEED FOR PLANTING.

Dr. GUSTAV MAREK has recently published a valuable paper on this important subject, embodying the results of a great number of experiments made by him at the experimental stations at Halle and Leipsic. Most convincing proof of the superior value of large seed is furnished by the results of some of his experiments in the garden. Beans and Peas were planted in the garden, small and large seeds of each kind being planted on adjacent plots, the Beans 12 inches apart each way, and the Peas in rows 10 inches apart and 2 inches asunder in the row. The crop was carefully harvested, and measured when ripe, and the progress of growth was closely watched during the season. The larger and more uniform growth of the plants from the larger seeds, from the beginning to the end of the season, is shown in the condensed tabular form in which we have arranged the results of these experiments. Height is given in inches and weight in ounces, if not otherwise specified.

	BEANS.	Plants from Large Small Seed. Seed.
May 23rd.—Height of plants	...	6-8 3-9
Average number of leaves	...	8 6
June 9th.—Height of plants	...	12-5 10-11
June 11th.—Number of plants in bloom	...	45 12
June 17th.—All the plants in blossom. taken up from each plot. Average height of plants	...	24 20
Average number of leaves on each plant	...	13 11
Aggregate weight of the ten plants when dry, in grains	...	837 576
July 31st.—Pods fully formed. Whole number of pods	...	3,138 2,789
August 6th.—Crop harvested. Total weight of vines and pods	...	219 183
Weight of seed, first quality	...	162 121
Weight of seed, second quality	...	6 25

In whatever way the plants are compared, and however minute the measurements that are made, the advantage remains always with the plants from the large seed. The much greater uniformity of growth cannot be shown in the table without taking too much space, but it appears all through the details given in the original paper. To give one or two instances:—Of the ten plants taken up June 11th. all but one of those from the large seed had its leaves as given in the table, and the odd one had twelve leaves; on the other hand, of the plants from the small seed some had ten, some eleven, and some twelve leaves, and one had thirteen. The uniformity of the plants from the large seed was marked. At the rate given in the above table the increased yield per acre of seed of the first quality that may be obtained by the use of large seed rather than small would be 250 lbs. A similar course of experiments with Peas gave the following results:

	PEAS.	Plants from Large Small Seed. Seed.
May 23rd.—Height of plants	...	6-8 4-5
June 6th.—Height of plants	...	18 10-12
June 19th.—Ten average plants taken up from each plot: Average height of these plants	...	41 34
Average number of leaves	...	15 13
Average weight of the ten plants, green	...	11-6 9
Ditto, dry	...	2 1-6
July 26th.—Crop harvested Total weight of vines and pods	...	201 163
Weight of seed, first quality	...	48-5 19
Ditto, second quality	...	19 37

In the case of the Peas as well as of the Beans, the plants from the larger seed were better throughout the season than those from the small seed: the superiority of the former was specially marked in respect to the quality of the seed harvested, as shown in the table. Professor Lehmann, of Munich, carried out a somewhat similar course of experiments with the same plants, and with still more striking results in favour of the use of large and carefully-selected seed; and in his experiments not only did the larger seed yield a larger crop from the same number of plants, but a much larger proportion of the small seed failed to germinate in the garden, or at least to push the young plants to the surface of the ground, than of the large seed.

Berried Aucubas.—It is perhaps fortunate that the berries of the Aucuba are not ripe at Christmas, as, with the mania that there exists for cutting off everything that bears the semblance of a red berry for house or church decoration, these pretty shrubs would soon be reduced to the condition of bare stumps. I find by experience that elevating the male plants above the females is the most effective way to secure a good crop of berries. Whether insect agency assists in the fertilisation or not, there can be little doubt that the pollen is conveyed in the air over the whole of the plant to be fertilised, and all the blossoms are regularly set. In a garden near here is a large female plant growing on a sloping border with a south aspect, the growth of which, though robust, is not luxuriant. Prior to its flowering in the summer, a small male plant was placed

in a box which was elevated above it, and the result is seen in a marvellous crop of berries all over the plant. It will, before long, be a grand specimen.—A. D.

Two Good New Hardy Shrubs.—I am happy to be able to inform your readers, who are fond of hardy ornamental shrubs, that the beautiful and distinct *Aralia quinquefolia* has proved itself perfectly hardy in the extreme north of Ireland, where it withstood thirteen degrees of frost unprotected without suffering in the least therefrom. This plant might probably be more correctly described as *Fatsia* than *Aralia*, as it is quite in the way of the shrub known as *Aralia Sieboldii*, whose correct designation is *Fatsia japonica*. *Cinnamomum sericeum* has also most unexpectedly proved itself to be perfectly hardy with me in the County Cork. Though we have had unusually severe frost this winter for our mild, moist climate, even the young growth of this summer, which, in many reputedly hardy shrubs was burned and shrivelled up, was quite uninjured on this Cinnamon.—W. E. G.

Lebanon and its Cedars.—All who have visited Mount Lebanon agree that its Cedars have become very scarce. Ranwolf, who counted them in 1575, found twenty-four; Mandrell, in 1696, could only discover sixteen; whilst Labillardiere, about a century later, found in all about one hundred, of which seven were much larger than the rest; none of these three travellers could, however, find any young ones. Although there are so few Cedars on Lebanon itself, I have always understood that they still exist in comparative abundance on other mountains north of Lebanon, and invariably on their summits. The fact that this Cedar loves humidity, and is now only found on the confines of perpetual snow, has induced some to imagine that Lebanon could never have been covered by this particular tree, the term Cedar being probably a free translation of a word which might have been applied with equal right to the Cypress tribe. I should feel much pleasure in seeing in your columns a full detailed account of this memorable mountain and its Cedars.—JOHN CORNHILL, *Byfleet*.

Growing Oaks there down.—In the spring of 1845 I planted with Acorns a piece of ground nearly 2 acres, in order to see how the Oaks would do without being transplanted. They were sown in rows 6 feet apart, and between each row we put in Larch as nurses. We had no stated times for thinning, but did it whenever we found that it was required, at the same time making selections of such as we considered the best plants for permanent growth. In pruning we left the dwarfest-growing around the selected ones, so as to get a good clear stem before allowing them to form a round head. The result is very satisfactory, inasmuch as the plantation consists of a beautiful lot of trees, averaging from 40 to 50 feet in height. The only difficulty or drawback connected with using Acorns is the depredations by mice and rooks. Rows in which were defects from this cause we re-planted, and Oaks thus raised have gone on better than any we ever raised from the nursery. I may add, that they are growing on a piece of land once cultivated by the late Mr. Loudon.—T. TWENTIS.

Domestic Trees.—Apple trees and all fruit trees have a domestic character which brings them into relationship with man. They have lost in a great measure the wild nature of the forest tree and have grown humanised by receiving the care of man, and by contributing to his wants. They have become a part of the family, and their individual characters are as well understood and appreciated as those of the human members. One tree is harsh and crabbed, another mild; one is churlish and illiberal, another exhausts itself with its free-hearted bounties. Even the shapes of Apple trees have great individuality, into such strange postures do they put themselves, and thrust their contorted branches so grotesquely in all directions. And when they have stood around a house for many years, and held converse with successive dynasties of occupants, and gladdened their hearts so often in the fruitful autumn, then it would seem almost sacrilege to cut them down.—NATHANIEL HAWTHORNE.

Wood Ashes.—These form a valuable manure, often procurable at home. It is rich in potash and soda, and may be used with good effect either by itself or mixed with other manures. Applied to lawns, it restores the verdure in a wonderful degree. A patch of underwood near here was burnt accidentally three years ago, and the spot has been quite marked since by the luxuriance and colour of the Grass. About gardens, wood ashes can be had in greater or less abundance almost every year. We are in the habit of saving all prunings and cuttings of fruit trees and shrubs, and burning them annually for the sake of the ashes and charcoal, contriving always to burn as much earth and general rubbish with them as possible at the same time, to increase the value and bulk of the material. It is a good manure for Vine borders, and is said to improve the colour of the berries.—J. S.

THE FLOWER GARDEN.

NEW WINTER-FLOWERING IRIS.

(XIPHION HISTRIO.)

THIS, when seen peeping through the ground in winter or early spring, reminds one of the common *Netted Iris* (*I. reticulata*); but its growth is rather taller, and the "fall petals" are broader and more conspicuously spotted, or rather blotched. Its colour is rich bluish-purple, flushed towards the base of the petals with rose-pink, the markings being of the deepest purple relieved by a medial ridge or crest of gold in the centre of the three external perianth segments. Its leaves are, like those of the *Netted Iris*, four-angled, and, like that beautiful plant, this also belongs to the bulbous group. When I first saw it pushing through the earth on an eastern border at Kew, in the winter of 1874, there was a little patch of snow beside the flower, and nothing could have set it off to better advantage than this, and a tuft of the vivid green *Poa annua*, with which it was also associated. This *Iris* is described as a native of Mount Lebanon and also of Mount Gerizim; it was sent to Kew by M. Berberey, of La Ferrière, near Geneva, in March, 1873, who describes it as nearly related to *I. reticulata*, from which it differs not only in structural characters, but in flowering six weeks earlier than that species. We have now before us flowers of it even more delicately pencilled and blotched than that lately figured in the "Botanical Magazine," and, while the flowers are there described as being inodorous, the blossoms thus freshly gathered are deliciously fragrant. Mr. P. Barr, from whom we have received the flowers in question, informs us that it has been in bloom with him for the last fortnight without having received any protection whatever. Its culture is by no means difficult. Treated like the last-named species it grows and blooms freely. Our engraving shows the size of the flower, and its colour as far as can be done by a wood-cut. This, with its allies, *I. reticulata* and *I. stylosa*, is well worth a place in sheltered positions in warm and deep rich soils and in every garden.

Xiphion (*Iris*) Histro.

CANNAS.

Few fine foliaged plants are more useful in gardens than these, and none are more easily grown or propagated. Seeds of the more popular varieties are offered by all nurserymen, and are very easily raised and increased. Seeds, for instance, sown in heat in February will form good plants for planting out-of-doors in sheltered situations in June, and are useful for furnishing the conservatory and plant stove throughout the autumn and winter. The fact is that since it was discovered that Cannas and many other plants of a similar character would bear open-air treatment and fill a niche with fine foliage in the sub-tropical garden throughout the summer, glasshouses have, in many cases, been somewhat denuded of beauty to add to that of the open air garden. There is no need to make such

mistakes, for Cannas in plenty may be had for all purposes in-doors and out.

Cannas under Glass.

Well-grown Cannas are almost equal to Musas or any other fine-foliaged plant, always excepting Palms and Ferns, for house decoration. The plants from seeds sown early in the spring, and subjected to a moderate temperature of 60° or so, invariably have a freshness, size, and beauty of flower and foliage which they seldom attain out-of-doors. The flower of the *Canna* has been of but little use for sub-tropical purposes. Under glass, however, the elegant branched spikes of flowers, ranging in colour through yellowish-red, orange-red, scarlet, crimson, and bright red, prove attractive. Some of them are also mottled with different colours. The seed, hard and black, from which the *Canna* has received the name of *Indian Shot* (at the base of the flower spike), is also an object of beauty and interest. Doubtless, however, the leaves are the chief attraction

of *Cannas*, and their habit and stature, ranging from 2 to 3 feet, fit them admirably for forming groups, centres, or lines in glasshouses. The effect of *Cannas* in pots is often much marred by growing too many together in one pot. In small houses, and as furniture to shelves or narrow borders, *Cannas* are most effective when grown as single plants. Treated thus, they produce quite a different effect to the ordinary huge masses that one meets with even in small houses, perhaps a dozen in a 12-inch pot. Again, *Cannas* may often be planted out with excellent effect to form groups of foliage here and there in the centre of the bed of conservatories, to relieve the glare of the ordinary kinds of conservatory plants. They also look well against roof pillars supporting the base of such that are clothed with climbers of the usual sorts. Groups of them planted out are also most useful for furnishing shady places in the backs of borders in out-of-the-way corners—for *Cannas* will grow fairly well in the shade. Being easily raised alike from seed and by root division, and bearing the dry air of dwelling rooms with comparative impunity, *Cannas* are among the most useful plants for furnishing

rooms, halls, staircases, &c., being fine foliaged plants, and at once dignified and elegant. By growing a few plants late in pots, *Cannas* would prove useful for furnishing small plant stoves that were mostly devoted to the culture of *Caladiums*, *Gloxinias*, *Achimenes*, &c., in summer. Such houses where no extensive collection of stove plants are grown, and but few winter-flowering plants, often have a poor unfurnished look in winter. By furnishing them with *Cannas*, the houses would look well, while useful material would also be held in readiness for room or conservatory furnishing if needed. The *Canna* is not at all particular as to soil. Two parts of loam to one of leaf mould, or thoroughly decomposed farm-yard manure, with a little rough sand, suits it well. It is readily raised from seeds, which may be steeped in tepid water for twelve or twenty-four hours before sowing, to facilitate their vegetation, as the seeds are hard. They also come up all the sooner if sown in a *Cucumber frame*, or subjected to a temperature of 65° to 75°, though they will vegetate in a much cooler place. As soon as fairly up, the plants should be potted

off singly, taking care not to break nor injure the somewhat fleshy roots. Shift on as the plants grow, and finally place them, if to be used singly, in 6 or 8, or at the most 10-inch pots. As regards their culture, it may be said that the more liberal their treatment, and the higher the temperature (up to 70°), in which they are kept, the faster they will grow. But they will do very well in a temperature of 50° or 55°. They also bear manure-water well, and will respond to liberal feeding by the enlarged size and deeper colour of the leaves, and the longer and finer spikes of flowers. The only care that Cannas in a dormant state need, is to see that neither the roots nor crowns are frozen, and that they are kept rather dry. A temperature of 40° to 45° suits them well, but they are so hardy that they may be wintered in the open air. In that case the bottom of their root-run should be made dry by extra drainage, so that no stagnant water can stand upon the roots. Planted in good loam, over a substratum of brickbats 6 inches in thickness, and with the crowns covered with leaves or litter in the way that Fuchsias and Tea-Roses are often treated, Cannas winter well in the open air. It is, however, safer in a general way to take them up and store them closely together on the floor of a root cellar or fruit room, or under a stage in a house from which frost is excluded. Of course those grown in pots should receive similar protection; and if any are wintered in the stove, they must not suddenly be thrust out into a low temperature during cold weather, or the sudden transition from heat to cold may kill the plants, roots and all. As regards the use of Cannas out-of-doors, there cannot be a doubt that they are the very cheapest, and among the most effective, of all the so-called sub-tropical plants. The simplest way of treating them for this purpose is to plant out in good rich soil either in masses or lines about the 1st of June. Water freely with manure-water should the weather be dry, and the plants must do well, unless the weather prove unusually cold. About the middle of October, lift the plants and store them closely together on the floor of a cellar, house, or cold pit. In February or March, pull the Cannas to pieces, and pot each piece separately if the object be rapid increase. A better plan than potting is to make up a slight hot-bed in a pit, cover with 6 or 10 inches of loam and leaf mould, divide the Cannas, and plant them out on this bed, and by proper attention to watering and giving air, the result will be a perfect jungle of magnificent Cannas to plant outside in June. A spade should be used for transferring the plants from the pit to their decorative quarters; and if the plants be carefully moved and watered in their new home, they will grow away without check, and the effect will be immediate and also permanent. There is yet another mode of treating the old stools—keep them entire and as backward as possible. About the middle or towards the end of May prepare rich and sheltered spots on lawns, shrubberies, or borders, by removing the old soil, and re-placing it with one yard or so of loam and manure. Plant the Cannas on these, burying the crowns a little deeper than they were before, and mark how massive and rich a single Canna root stock can become.

Among the finer sorts in in-door or out are *Canna metallica*, *C. nigricans*, *C. Van Houttei*, *C. peruviana*, *C. maxima*, *C. expansa*, *C. discolor*, *C. floribunda*, *C. Bihorelli*, *C. grandiflora floribunda*, *C. Rendatleri*, *C. rubra superbissima*, *C. aurea*, *C. glauca*, *C. compacta*, *C. Warczewiczii* major, and *C. Edouard Morren*. Packages of seed may be had from 1s. to 2s. 6d. per packet, and plants of named varieties from 8s. to 24s. per doz. In no other tribe of plants is it possible to purchase so much permanent tropical-like beauty for so little money. It may be added that the arrow-like flowers of the Canna, carefully mounted, have a unique effect in floral arrangements, while few plants are more useful for cutting in masses for furnishing large vases or baskets for ball-rooms, &c. Canna leaves may also be used in lieu of Palms, Ferns, or other fine-foliaged plants for decorative purposes. D. T. F.

THE HOLLYHOCK.

I KNOW not whether the wet summer of the present year had anything to do with it, but it is quite certain that the much-dreaded Hollyhock fungus has been much less destructive this season than it was last year, when the summer was drier; yet there have not been wanting indications that it is yet amongst us, though its destructive tendencies have been much less marked. This comparative freedom from the pest seems to point to the fact that the Hollyhock flourishes best when kept moist at the root. It is a plant requiring a generous growth, for strong roots, when planted in good soil, send up shoots of amazing vigour, moisture at the root and falling rain on the foliage keeping the plants robust and healthy in appearance. As regards the propagation of this plant, it may be said that grafting is a mode that at one time was applied more than it is in the present day; and was effected about the month of March. First, if the growers had any seedlings in pots with stems of the thickness of a pencil, or even thicker, he would cut them away almost down to the surface of the soil, at the same time taking out a little of the mould; then the scots required to be increased were side-grafted on the seedling stocks. This process might be denominated whip-grafting, and the scion, made of an eye, was tied tightly to the stock by means of a piece of bast. When the grafting was finished, the mould was put back deep enough to cover the graft and exclude air, and the pots were then plunged in a gentle bottom-heat for two or three weeks, the plants being ready for a shift at the end of that time; they were then gradually hardened off till required for planting out. The best plan of getting up a stock of plants is by propagating in summer by means of "eyes." All the side shoots should be allowed to remain on the plants till they get a little ripe, and this stage of growth is soon known by reason of their light brown colour. These side shoots may then be divided by cutting them below the eye and leaf-stalk, and about 3 inches above, leaving leaf and stalk on to assist in developing the eye. A small cold frame is one of the best contrivances in which to plant the eyes, placing them in a bed of sifted leaf mould and sand some 6 inches in depth, planting each variety by itself, and all in regular lines. It is always well to water as little as possible, and therefore the compost should be used moist, and the frame shaded, to retain this moisture in the soil as long as possible. Cuttings may be struck in this way with great success; and, as soon as they begin to throw up a few leaves, they are ready for potting off. Young growing plants of Hollyhocks should never be allowed to become pot-bound, or the flower-stem is apt to be thrown up too early. Therefore, the aim of the cultivator should be to keep the roots moving previous to planting out by shifting into larger pots as required, till they are in 6-inch pots, when they will be fine plants for planting out to flower. The Hollyhock thrives best in a somewhat stiff clayey loam; if too cold and stiff a good quantity of rotted turf and decayed vegetable refuse may be added to keep it open. The ground should be trenched 2 feet deep before planting, mixing in at the same time a good quantity of well-decomposed manure. Just previous to planting the soil should be turned up once more to get it thoroughly mixed and workable. This work should always be done when the ground is dry, otherwise it is apt to become sour, and the plants do not thrive. If a plantation of Hollyhocks is wanted, the plants should be about 3½ feet apart, and some 4 feet apart in the rows. This enables the cultivator to get among the plants and give them all the attention they require. It is well to put some leaf mould about the roots at the time of planting, as it serves to start the roots and gives them something to lay hold of at once. Planting should be finished early in April at the latest, and if the weather prove dry afterwards, and through May and June, some water must be given twice or so a week, when the flower-stems are forming. Water should be carefully applied if the spikes are wanted for exhibition purposes; and, as an old florist once remarked, "If too much water be given at this stage, there is a danger of the buds forming widely on the spike, which gives it a very irregular appearance when in flower; rather mulch to keep out the drought." When the flowers are all well formed and the spike is getting well covered with them, some manure-water may be applied; but if the plants are healthy and strong, and the soil in which they are growing is rich, it is scarcely necessary to apply it, as the flowers are certain to be fine and symmetrical. In selecting spikes for exhibition purposes, the healthiest and most regularly set spikes should be fixed upon—say about three weeks before they are wanted—and they should be shortened back to about 4 feet of flowers. The reason for doing this is that the flowers fill out better and burst more regularly. As a matter of course cultivators have to depend very much on their own observation. As some varieties come into flower much quicker than others, much depends on the variety and the state of the weather at the time. When the flowers begin to open they should be shaded to keep the bottom ones back, the shading being gradually extended upwards, till the whole length of the spike that is required to make a good

Moss for Protecting Herbaceous Plants.—Mr. McGann (see p. 543, Vol. VIII.) suggests that herbaceous borders might be neatly carpeted with Moss during the dead season—a very pretty idea, but impracticable. In this open weather the blackbirds and thrushes are doing good service in the borders in question by picking up worms, grubs, and all sorts of vermin. Were the borders truly carpeted on Mr. McGann's plan, these busy little assistants would make short work of it, scraping it up in every direction to get at food below.—SALMONCES.

one is shaded. For exhibition purposes there is nothing like a good length of full-blown blooms. A very good material for shading the light flowers, is what is known as pack sheeting, a thin, light material, of which two thicknesses should be used on some parts if necessary, which will generally be on the side next the sun. Tiffany will do well for the darker sorts. By being too closely shaded the dark flowers often get spoiled in colour. A piece of oil-cloth, or any waterproof article, should be placed on the top in wet weather to throw the rain off, as it is of great importance to keep the flowers dry, especially when they are getting into full bloom. The cloth should be furnished with tapes to tie and untie readily, as it is sometimes necessary to take the shading off to allow the sun and air to dry the flowers when any dampness gathers about them. For the purpose of providing the skeleton of the shade take two poles, place one on each side of the flower-stem, about 2½ feet apart, and bring them together at the top by means of a hoop 1 foot or so in diameter; fasten a stick across the top of the poles, and to this tie the top of the spike to keep it from shaking, as the supporting stake against the plant will be withdrawn. Then another hoop should be placed about the middle of the frame, and the hoops can be made of strong Willows, light suckers of Ash, or pieces of ordinary cane. Take a piece of strong string, fasten it to the top hoop, give it a turn round the next, and fasten to a strong peg driven into the ground or secure it to one of the upright stakes, similar fastenings being made on the other side. The two strings answer the purpose of two poles, and keep the cloth from rubbing against the flowers. Such, then, is the mode in which a Hollyhock "crinoline" is formed. These crinolines are rather unsightly things in a garden, but the grower who exhibits must for the time sacrifice the picturesque, if he would win at the exhibition table. The following list comprises some of the finest varieties of the Hollyhock in cultivation.—Alba anperba, pure white; Carus Chater, reddish-crimson; Bullion, golden-yellow, extra fine; Constance, delicate pale flesh; Crimson King, deep cherry-red; Eclipse, bright rose-red; Excelsior, rich shining maroon; Edward Speed; French White, suffused with deep purple; Fire King, glowing reddish-crimson; Golden Drop, deep bright yellow; Incomparable, heavily tinted apricot; Jessie Dean, clear apricot tinted with yellow; James Allen, bright plum; Junia, pale primrose, suffused with purple; Marvellous, deep orange-buff; Nonpareil, rich dark purplish-maroon; Queen of Yellows, clear bright yellow; Rose d'Amour, rose-peach; Rosy Queen, delicate rose; Ruby Queen, deep shining ruby; Selina, pale creamy flesh, carmine base; Triumph, very dark crimson; Tyrian Prince, rich crimson-purple; Walden King, bright scarlet; Walden Queen, soft delicate flesh; and Walden Primrose, clear pale primrose, extra fine. Quo.

RAISING GLADIOLI FROM SEEDS.

Mr. BOSSIN, a well-known and successful hybridiser, tells, in the "Revue Horticole," how he raises his Gladioli. Those who intend to sow them should take care to collect the seeds from the finest plants only. After removal from the capsules, they should be laid out to dry for a few days, and then be put away in paper bags until the time comes for sowing, which will be in November or December, or in February and March. I sow every year in autumn, and my mode of proceeding is this:—In November or December I take some earthenware pans, or large pots or boxes, and fill them with peat earth to which a few handfuls of good rich loam, well mixed beforehand with rotted dung, has been added. When the pans or pots are ready, they are filled with the compost to within 1½ to 2 inches of the rim. On the top we put half an inch of pure sandy peat earth, sprinkle the seeds evenly thereon, and press them in with the back of the hand, covering them in with a quarter of an inch more of fine peat. I leave the pans or pots out of doors until rain or frost comes, and then remove them to a dry greenhouse, where they are housed for the winter, getting very little water; and only when the soil is quite dry, as any excess of moisture would rot the seeds. Whilst they are in the greenhouse care must be taken that the mice do not eat the seeds. At the end of February, or quite the beginning of March, the seeds begin to germinate, and soon a crop of small plants is seen, presenting the appearance of fine Grass. When the winter is over, the pots or pans are placed out of doors again, choosing a good position, where they are sheltered from the frost and cold spring rains. They are then left to grow without further care beyond watering and pulling up the weeds that appear amongst them. When autumn comes—that is to say, in November—I take up the small bulbs and dry them. When dried they are packed away in large pots with some fine dry sand at the bottom, putting in a layer of bulbs and a layer of sand alternately. In this way they are kept through the winter in a dry place where it is neither too hot nor too

cold, and at the end of February are pricked out at distances of 4 to 6 inches apart every way, in beds covered with frames to keep out the frost. Towards the end of May the lights are taken off and the plants are treated like old ones. In the course of the month of August some flowers will be already visible on the two-year old plants; but for the general blooming we must wait till the third year, when the bulbs will be somewhat larger and better shaped than in the year previous. I take them up again in autumn, and keep them in sand through the winter, as before. Early in February I prepare the beds to receive the three-year-old bulbs, choosing a suitable spot where the ground has been well manured the year before, fresh manure being detrimental to all bulbs, and particularly so to Gladioli. When the beds have been got ready and well raked over, I draw five equidistant lines across them a foot apart, along each of which I set in a row of bulbs at 12 inches apart and 3 or 4 inches below the surface. This is done about the end of February, and, if frost supervenes, the beds must be covered over with litter or mats until the danger is past. I have magnificent displays of Gladioli, treated thus, as may anyone else who will follow the directions above given.

A NEGLECTED FLOWER.

THE RANUNCULUS.

IN the round of favourite flowers grown by florists of a generation since, there often used to come in due succession between the Pink and the Pinks, and in most refreshing contrast to all before and after it—the Ranunculus. Now its place in such a garden circle is often vacant. Not many Tully cabinets have now their few drawers at the bottom for Ranunculuses. It is a great pity, because the flower is full of capabilities and properties attractive to the florist. It possesses great command of colour. In the self varieties there are crimson and purple-blacks, scarlet, red, rose, pink, and white. In yellows, orange, lemon, cream; also white. There are classes of white and yellow grounds with tips and edges, mottles and stripes of various colours, usually some shade of purple, brown, rose, and red, and in addition to these are some curious roans—grey and red—that are a fancy dress peculiar to the Ranunculus. One of the chief charms of this flower, particularly to a florist, is that it is very sportive and vigorous from seed, so much so that a seedling-bed is, perhaps, the great surprise and charm of Ranunculus-growing. Even the most double exhibition flower will frequently afford a seed head when fully expanded, but very seldom any stamens. Pollen must, therefore, be obtained from well-shaped and coloured semi-doubles that afford it freely. Good seed somewhat resembles scales or flakes of bran with a slight brown germ set in the middle. It is very delicate, and like seed of the *Auricula* is better left uncovered by any soil, and the soil kept generally moist by a sheet of glass over it. Sowing may be done at the time the old tubers are planted—about the end of February. The Ranunculus has, no doubt, an ill name for being a crotchety, ill-tempered old flower, a punctilious tuber requiring everything to its own good liking, or else declining to bloom. The plant is, indeed, particular in some of its requirements, but troublesome in none. It is exact but not exacting. It requires precisely its 1½ inches underground, otherwise the new tuber which is naturally formed over the very neck or woolly crest of the old one will endeavour to rectify matters by diving down or coming up by means of a sort of underground stem, dropping several of its claws in the course of it, and making an awkward if not weakened root. At planting time I always wet the tubers twenty-four hours beforehand; they then swell marvellously, and do not literally get up and walk out of bed, as they often do when planted dry. Moistening them also enables one to detect any diseased or rotten claw, which ought to be removed, but cannot be easily detected in a dry state. The claws when thus swelled are not brittle or liable to be snapped off so easily at planting. Knocking off a healthy claw is so much loss of stored-up strength, and it is worth while to be careful. Another emphatic demand of the Ranunculus is a firm bed for growing in. If I were doomed to take those forced and dismal walks called "constitutional," I would never forget to take some over my next year's Ranunculus bed. It would be a walk "with an object."

There are matters which the Ranunculus is more particular about than soil, though it likes that good and hearty. Mr. Tyso, the present representative of this flower, most wisely, because most naturally, says that a bed made up of turfy sods from a strong pasture where the Buttercup grows will suit our member of that family, the Ranunculus. This is the best advice that can be given where the native soil of the garden is not a deep retentive, yet well drained loam, or one that will grow a hearty Cabbage. Enrichment of cow or horse manure may be used, but it must be thoroughly well decayed, and the bed is far the best when made up in October.

Again, another vital point in *Ranunculus* culture is a well-aired bed for sleeping in—that is, a scrupulously dry storage when out of the ground. This has literally to be shelved for more than six months out of twelve, owing to its foliage, which would naturally spring afresh in autumn, not being hardy enough to certainly bear our winters. It is therefore forced to rest from about the third week in July to the third week in February. Where there is the slightest dampness the naked tubers are peculiarly liable to contract blue mould at the neck. It is generally fatal, disorganising the claws and eating into the heart, and when in the ground the whole structure rots. The only thing I know of for affected tubers is to dust them thoroughly with dry brimstone, and keep them from further damp. Rotten claws may be detected by their soft consistency, brown colour, and by the moistening process I have spoken of. Healthy claws are white inside. Prevention is better than cure. I reserve for my last note a deeply important crisis in the culture of the *Ranunculus*; this is, taking up. No amount of attention to soil or anything else will atone for negligence here. The new tubers strike directly the vigour of the bloom and foliage is past, and every new fibre struck out and afterwards unnaturally checked is weakness to the tuber. It must not only be replaced at some expense, but easily affords a starting point for mildew to lay hold of. The bloom ought to be shaded, for the first heavy rain upon expanded flowers will beat all down, and break many. The cover should be left on till all are taken up, and it will thus keep the ground cool and dry, and free from the warm stimulants of July rains and sun upon the excitable tubers. I never water my beds artificially, preferring to shade them against very hot sun. But a dry May is always against the *Ranunculus*, and watering seems to weigh little in their favour when the air is dry and weather rainless.

In Rome I saw, a few years since, a bed of *Ranunculuses* that were just opening their buds about the beginning of February. They were double, and had some edged flowers among them, but the full quality I could not discern. I thought how grandly this neglected flower might be grown where it could remain to form clumps, only to be moved a moment for re-arrangement. Were it in my power this is how I would grow my *Ranunculus*—I would yearly top-dress the beds and re-plant immediately, affording the foliage a glass protection as of a house that freely admitted light and ventilation, and was entirely frost-proof. But this is not the place to build glass castles in the air. I have known the florist *Ranunculus* since my boyhood, and I go on with it in the old way. I have had failures and successes, success surviving the partial shock of failures. Perhaps a chequered experience like this, being natural, is a useful sort of one to recall. I am glad to say a word for one of my dear old favourites, and if it will be of help or interest to any fellow cultivator, or if it will lead any young florist or older hand to say "I will make love to the *Ranunculus*," it would then repay me for a congenial scribble.—F. D. HORNER, in "Journal of Horticulture."

Ophiopogon japonicus as an Edging Plant.—This plant, which has all the aspect of a Squill, was used in the beautiful gardens of Bellagio as a substitute for Box edging, especially along the walks under trees, and it seemed to fulfil its purpose most satisfactorily. It belongs, I believe, to the Liliaceæ. The roots are so tortuous and interlaced as those of the Lily of the Valley. The flowers are quite hidden by the long, dense, and Grass-like leaves; they are of an iron blue, and, as I have said, like those of *Scilla autumnalis*. The plant was new to me, and was named for me by M. Edmond Boissier, whose name is so well known as a collector of Alpines among the Sierras of the Spanish Peninsula. He also pointed out to me a Spurge (*Euphorbia marginata*), supposed to be an American species, with the leaves symmetrically bordered with white. The effect of this was charming when growing near dark-foliaged plants.—PETER INCHBALD, *Hovingham Lodge, York.*

The Large-flowered Christmas Rose.—I have to thank Miss Hope for giving us such ample notes about this interesting plant, and especially for amending my statement that it is very easily increased. My reasons for saying so were:—First, that a very small plant, which Miss Hope was kind enough to give me in 1872, has increased so much in size as to have been for two months the principal ornament of the border in which it is placed; and secondly, because I had the pleasure last October of inspecting a bed filled with young plants at Wardie Lodge. At all events, we may be grateful that this beautiful and rare plant is not so slow or difficult in propagation as, for instance, *Trillium grandiflorum*, *Rhexia virginica*, *Spigelia marilandica*, and others. The fact that this variety has not seeded seems certainly to point to a hybrid origin. *Helleborus niger* is just coming into flower, with orientalis, whereas *niger* major or maximus began in October, and is still sending up immense flowers. The present scientific name is extremely awkward, and the

variety is so perfectly distinct from any other, that I think it should be called *Helleborus aberdoniensis*, a name which points to the northern origin of the plant. Miss Hope deserves thanks for raising her voice against the growing habit of forcing hardy plants. There is no excuse for it. The conservatory can be supplied with numberless exotics—let our seasons be marked by the return of hardy flowers at their appointed time. They will be all the dearer to us, and not less plentiful. If Alpines and hardy flowers are grown under cover, let it be either in pots in a cold frame, or, better still, in an Alpine house, which is a thing we should see often than we do.—SALMONICERS.

The History of the Auricula.—In a pamphlet entitled "Die Geschichte der Aurikel," Professor Kerner traces the history of the discovery and cultivation of this plant, from the time of L'Escluse (Clusius), who first transplanted this species and the hybrid *P. pubescens*, Jacq., in 1582, from the Tyrolean Alps to Belgium. The latter species, and not the true *P. Auricula* L., which quickly disappeared from cultivation, is believed by Professor Kerner to be the real ancestor of the cultivated *Auriculas* of our gardens. The two were known at the time of Clusius under the names of "*Auricularia* I." and "*Auricularia* II.," from the supposed resemblance in the shape of the leaves to that of the ear of a bear. The hybrid *P. pubescens*, which had been lost from the German and Austrian Alps for nearly three centuries, was re-discovered by Prof. Kerner in 1867 in a single locality in the Tyrol.

Rock-work v. Root-work.—I dislike monotony as much as anybody, and quite agree with Mr. Groom (see p. 53L, Vol. VIII.), as to the need of securing "individuality" in our gardens; but the very common practice of massing a few roots or stumps together, and fancying that they will prove a home for Alpine and similar flowers, is actually a source of monotony in many gardens. It is, moreover, wrong as regards Alpine flowers, for the following reasons:—the root-work crumbles away in time, and this prevents the ground being firmly consolidated, a necessity for Alpine plants. Dry rot and evil-smelling fungi take possession of it; it harbours vermin of many kinds; and it is offensive to the eye in connection with Alpine flowers, because all who have seen these in their wild haunts know they seem the rocks and cushion the stones, but that roots of trees are rarely or never seen in connection with them. The roots have not at all the same effect as the rocks in preventing evaporation from the soil, and affording a cool firm feeding ground to the roots—which are absolute necessities for Alpine flowers. No doubt a person of good taste may so employ picturesque old stumps that a good effect may be produced; but root-work, employed as it generally is, is a great mistake. W. S.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rock-work for Alpines v. Root-work.—True Alpines should never be seen on root-work. There are many objections to root-work. It is never in itself a pretty object, it harbours slugs and other vermin much more than stone-work, and Fungus—a sure foe to higher plant life—grows readily on it. If used at all, it should be kept in the Fernery.—SALMONICERS.

Roses on the Seeding Briar.—I have just received a few dozen charming little plants on this stock. Their clean growth and really good roots show how well suited it is as a stock for most kinds of Roses.—E. CHILWELL.

Stantonia latifolia in Wiltshire.—This handsome foliaged climber is hardy here on a south wall. I planted it in my garden some six or seven years ago, and although never protected in any way during winter, it is now a large vigorous plant. Many of its beautiful glossy leaves are from 5 to 6 inches long, and from 2 to 2½ inches broad. It has not yet flowered, and its flowers are not very conspicuous, but they are sweetly scented.—G. B. LONLEY.

The Gladwin (*Iris fetidissima*) as Undergrowth.—In addition to the merits of this plant as a fern-bearer, it makes the best evergreen undergrowth below large trees with which I am acquainted, even when too dry and impoverished for almost anything to grow. The Gladwin in company with St. John's Wort and Perrywinkle, makes an effective and cheerful combination at all seasons.—J. GAOAR.

Rehema Weibachia Lamprocerus.—This is one of the most useful winter flowering plants we have. It is a light green, smooth-edged Bromeliad, with purple flowers on a crimson stem. In a 4-inch pot it makes a most useful plant for general decoration. It thrives well in a moist cool Orchid-house, and it is best grown in Sphagnum Moss and sand, but any light material will answer for this easily grown, and will remain in beauty in a room for weeks together.—CHRISTIAN.

Pyrola secunda.—Of the *Pyrolas*, six of which are wild in Switzerland, none interested me so much as *P. secunda*. It differs from the others in having the raceme secund or unilateral. The flowers are of a whitish-green, and numerous. The style is protruded beyond the well-shaped corolla. This species is rare in England, though not unfrequent in the shady woods of Scotland. In Switzerland I met with it in Pine woods, where I saw it chiefly growing by the forest paths.—P. I., *Hovingham Lodge.*

The Caper Plant (*Capparis spinosa*) in Flower.—On the Lake of Como—growing by the hotel gardens—I noticed the beautiful sprays of this trailing plant, the flowers of which are simply lovely, and the tender and delicate green of the foliage harmonises therewith to perfection. The flowers reminded me of those of *Spartanum*, with their parti-coloured stamens and whitish petals; they are axillary, and as they burst from the shining evergreen leaves, displaying their dappled stamens, they must win the admiration of the most indifferent.—P. I.

THE INDOOR GARDEN.

ZONAL PELARGONIUMS FOR WINTER DECORATION.

I AM indebted to "W. D. C." for his reply to my remarks upon the winter flowering properties of the Zonal Pelargonium, and I am pleased to find that we agree in our estimation of its value in that respect. The Zonal Pelargonium I know cannot be flowered in perfection during the winter months in a cool house, nor in a damp atmosphere. My impression was from the tenor of "W. D. C.'s" observations (see p. 536, Vol. VIII.) that he alluded to the decoration of conservatories that are attached to, and approached from, the dwelling-house, and are usually kept warm and dry, and supplied with a succession of flowering plants from reserve houses. I had again this Christmas Day the pleasure of admiring the display of Zonal Pelargonium flowers on my friend's dinner table, and the enlivening effect of many varieties in full flower interspersed among foliage plants in the conservatories. So much value does my friend's gardener set upon the Zonal Pelargonium, for its decorative qualities at this season of the year, that a long house is devoted exclusively to its cultivation, from which the conservatories are supplied with fresh plants as needed, and the house with cut blooms. This house was as full of flower as it could have been, had it been mid-summer instead of Christmas day. Another house is devoted to the cultivation of foliage plants for replenishing the conservatories, and for the purpose of cutting from for house and table decoration; for the latter, of course, the varieties of Maiden-hair Fern predominate. "W. D. C." asks me to give a list of such varieties of Pelargoniums as I consider most suitable for winter cultivation. I feel some diffidence in complying with this request, because I cannot do justice to the productions of my brother Pelargonium raisers, my observations being confined almost entirely to kinds of my own raising—as I grow only to breed from, and I must plead guilty to having drifted into the usual error that befalls most raisers of florists' flowers, viz., that of breeding in and in; hence, the distinctive characters of our strains. One of my special aims has been to produce perpetual flowering properties, and the originators of my strain, viz., Lord Derby, Leonidas, Celestial, and Louis Veullot, are all free winter flowerers, especially Louis Veullot, from which variety, as pollen parent, most of my dark-coloured seedlings derived their origin. Diana has been named as the best variety for winter flowering. The male parent of this variety was Louis Veullot, and Lord Derby the seed-bearing parent. I noted in flower in my friend's houses on Christmas Day Jessica, Sir John Moore, Nelson, Richard Cour de Lion, Renzi, Oberon, Brasidas, Alonzo, Salathiel, Enoe, Hebe, Astarte, Aspasia, Idalia, Imogen, Minerva, Lurline, Iago, Ianthé, and many other of my seedlings not named, which, from being considered too good to destroy, have found their way into my friend's houses, under conditions that they are on no account to go off his premises. Pain's Perpetual and Vesuvius are winter flowerers, but not of the florists' class. Several varieties of M. Postan's and Mr. George's raising I have seen quoted lately as remarkably good kinds, and I believe that Mr. Pearson's splendid strains of hybrid nosegay varieties are for the most part good winter flowerers.

JOHN DENNY.

GARDENIAS.

Nobody ever tires of the fragrance of Gardenias, or Cape Jasmines, as they are usually called. Their usefulness for cutting can only be matched by their sweetness. Growers of flowers for market have filled houses with them, and in this way they have been made as common and as cheap as Camellias or Roses. Gardenias are divided into stove and greenhouse varieties; but the distinction is deceptive, inasmuch as all Gardenias thrive best treated as stove plants when in a growing state. The latter expression again has led to misconception. Cultivators have mostly flowered their Gardenias in heat, and then forced them to rest in a cool and dry temperature till next year. This is, however, by no means necessary. By keeping the plants in heat they grow and flower, mature their buds, and flower and grow again throughout the season. Under this treatment the plants gain a robustness and vigour, and their leaves a size and a depth of glossy greenness to which they are utter strangers, as a rule, under the once-flowering-in-the-year course of treatment. Therefore, for continuity of bloom and simplicity of culture place Gardenias in a bottom and atmospheric temperature of from 65° to 70°, and leave them alone. We are usually told to prune the plants back as soon as they have finished flowering. That may be done if they are too large, but certainly not otherwise. No instructions could be more injurious. Gardenias left to themselves after flowering, or rather, as a rule, while they are flowering, throw out from one to three shoots from the base of the flower buds. By the time the flowers fade these shoots have made from four to six leaves, and have almost finished growing and begun to form fresh flower-buds. By pruning we simply cut away all these flowers and force the plant to produce new and not half such good or floriferous shoots, thus sacrificing at least three months' time. This process of throwing out fresh shoots and forming more flower buds is continuous, and, therefore, by keeping the plants growing and the knife from them, the flowering also becomes continuous. Of course the amount of bloom will depend a good deal upon the amount of light and heat to which they are subjected. Gardenias treated in the usual way flower and grow best in a brisk top-and-bottom heat of from 60° to 70°.

As soon as the flower buds for the next blooming season are formed or the growth finished, the plants may be moved to a lower temperature, and safely wintered in a house or pit at 45°. Some even keep them colder; but 45° is better than 40°, and the latter more favourable than any temperature below it. Gardenias in this state may be had in flower at any time when wanted by allowing six weeks of forcing treatment for the unfolding of their blossoms. *G. radicans*, perhaps more of a stove plant than any other; is a native of Sierra Leone, and is the only Indian or tropical variety that I think good enough to recommend, and, in the case of those whose space is limited, I would grow only this kind, *G. florida*, and *G. citriodora*. F.

A Late White Chrysanthemum.—The Chrysanthemum figured in the accompanying woodcut is one of the Anemone-flowered type, and is valuable for its pure white colour and lateness of bloom. The disk is quite white and well raised, as shown in the cut. We found it in Mr. Bullen's nursery at Lewisham, but the owner has no name for it. The distinct appearance of the blooms led to their meeting with a ready sale at the Christmas flower market.

White Anemone-flowered Chrysanthemum.

THE CULTIVATION OF FLOWERING STOVE PLANTS.

Amongst the immense numbers of plants cultivated in pots at the present day, many of the stove subjects stand unrivalled for the profusion of their gorgeous flowers and long-continued habit of blooming, alike unequalled for the decoration of heated glass structures and for affording a continuous supply of flowers for cutting. The hot as well as the somewhat cool regions of the Eastern hemisphere, and South America, with its vast extent of territory, have furnished us with a wealth of flowering plants of almost every form and hue, suitable for the decoration of the warm stove and intermediate house. In addition to the good qualities already mentioned, most stove plants possess the merit of being much easier to grow than the generality of greenhouse subjects as regards their requirements in both soil and water. Many kinds of stove plants, although they may do somewhat better in peat, can be grown in turfy loam, where this material cannot readily be obtained of good quality, and in respect to water they are not nearly so impatient of receiving a little more than they require or having it given them before they need it. For these reasons, many can succeed to a certain extent in the cultivation of stove plants who fail completely with the less facile inhabitants of the greenhouse. Another point in their favour is that, when grown to a size that would require more root room for their support than it may be deemed desirable to give them, the heads of the plants may be freely cut back, and the roots correspondingly reduced, a great portion of the old soil being taken away and replaced with new; this may, even with many hard-wooded species, be repeated as often as is found necessary and does away with the necessity for such large pots as would otherwise be requisite. All plants that require the application of fire heat, to maintain a temperature not only some degrees above freezing point, but one that is continually higher than that of a greenhouse, come under the denomination of stove plants. Yet, introduced as they are from so many different parts of the world—some intensely hot, others more temperate, according to the latitude or their more or less elevated position—they evidently, when existing in a state of cultivation, require a considerable difference in the temperature they are grown in. Hence, where an extensive collection of plants exists, all needing more or less heat to grow them, there should be at command the means of keeping those that require it warmer than others that will thrive in a lower temperature, or in quarters of a character intermediate between the hot stove and greenhouse. Where some arrangement of this sort does not exist, there must necessarily be a compromise in the treatment they receive, some being kept hotter than they need, whilst others are too cool. The respective requirements can only be met satisfactorily by the use of separate houses; or where one house is made to do duty, by having a glass division in it, and placing the plants wanting the most heat at the warmest end, and those that will flourish in a cooler temperature in the opposite department. An approach to accommodating all, according to their requirements of temperature, is often attempted by putting the most heat-loving subjects at the end of the house next the boiler, with the plants from the cooler regions at the coolest end; but this only meets the difficulty to a partial extent in the matter of heat, and effects little or nothing on another very important element, the humidity in the atmosphere, as also the amount of air to be given. Both these elements are of such a subtle nature that little control can be exercised over them, as regards regulating any considerable difference in their influence, in the opposite ends of a single house, so as to meet the requirements of the two sections of stove plants under consideration—the cooler of which in most cases, need a much drier condition of the atmosphere, even in the height of the growing season, as well as the admission of more air than would do well for such as are introduced from the hottest, lower-lying regions of the tropics. For instance, the lovely Madagascar *Stephanotis floribunda*, although a plant that will bear a strong heat, can rarely be induced to flower freely when grown in an atmosphere as moist as that required by the *Ixoras* from India, or the Brazilian *Dipladenias*. In the cultivation of flowering stove plants, one of the most essential matters is a house so constructed and situated as to afford as much light as possible. Without this it is vain to expect anything above

mediocrity in the results. This will be seen when it is considered how comparatively limited is the amount of cold external air that can be given, especially during the early part of the growing season, consequent upon its causing too great a reduction in the temperature, but still more by its producing too dry a condition of the atmosphere consistent with the absolute requirements of the plants. Their growth, as is well understood by those who have had even limited experience in the cultivation of stove subjects, is very rapid. For this and the preceding reason, unless they are grown in a house that will afford them a maximum of light, the wood and leaves are so soft and deficient in substance as to render them incapable of producing flowers either in their wanted quantity, size, or colour, light being the great compensating element that in a measure makes up for the deficiency of air in which plant life under such conditions exists. Hence, as I have already said, the stove should be so constructed as to afford an abundance of light, and so placed as to be in no way under the influence of buildings, trees, or walls that will either obstruct or absorb light. This is a matter of vital importance, which cannot be too forcibly impressed upon all who essay the cultivation of these plants. With this view, the stove should always be span-roofed, with upright side lights, so deep as to come down to the level of the side stages. In a lean-to, hip-roofed or even half-span-house, the back wall always absorbs so much light as to seriously interfere with the short-jointed, robust growth essential to success. The dimensions of the stove will, of course, be determined by individual requirements. A very useful size for the class of plants under notice is 18 feet in width by 35 or 40 feet in length; if it be narrower than this, it does not admit of the best and most economical internal arrangement; if above the width named, it necessitates the elevation being greater than is consistent with an easy maintenance of the required temperature in severe weather. It should consist of 3 feet of brickwork all round, with movable shutters in the sides. The upright side lights should be 3 feet in depth, and fixed, as the opening of these admits air in direct contact with the plants, than which nothing can be more objectionable or more calculated to check the tender growth.

There should be provision made for sufficient roof ventilation by an arrangement of short lights hinged to the ridges, so as to open with lever rods; this is so much an improvement on the old system of sliding lights that air can be given when required, even in wet weather. It is also infinitely superior to any of the contrivances of shutter ventilation at the ridge, as these always tend to darken the house too much. The internal arrangement may, with advantage, consist of 3 feet side stages, over the pipes, and on a level with the bottom of the side lights. In a house of the above width and elevation, for the hottest section of plants there should be five rows—three flows and two returns—of 4-inch pipes running round the house under the side stage. I do not recommend any piping under the tan-bed, being convinced that there is nothing gained by it. For the cooler stove four rows similarly placed will be enough. In all cases there should be on each side of the house three or four 9 feet lengths of trough piping—that is, hot water pipes with troughs cast on them when made—so that there can be all, or a portion only, as required, filled with water for evaporating to maintain the atmosphere in the moist condition necessary for the plants. Where no evaporating troughs exist, and there is no means of keeping up moisture, except by syringing the pipes and sprinkling the floors, there is no possibility of the atmosphere being continuously in the requisite condition; it will be at one time too moist, at another too dry. A path running on each side of the house about 3½ feet in width should divide the side stages from the centre, which ought to consist of a brick-built pit 3 feet in depth, to be kept filled with tan. The side stages should be made of solid slabs of slate or thin flags, on which can be placed an inch or so of fine gravel, which can be kept damp when required, and will so maintain moisture amongst the plants standing thereon. If these side stages are made of open bars of wood-work, too great heat, arising from the close proximity to the pipes, will affect the plants. The distance these stages are from the glass not only adapts them for standing the smallest plants upon, but will admit of moderate-

sized specimens on them. The largest growing subjects will, of course, occupy the centre of the house in such an arrangement as the above. In some cases, to make the most of the space, a shelf may be hung from the roof over each path; but with these there is this inseparable disadvantage—the light is intercepted from the other plants to a serious extent; consequently this counterbalances the gain, and the shelves are better absent. Of course, such an arrangement as this implies that all the plants are grown in pots or tubs.

At the present day some writers advocate the planting out of stove plants in preference to pot culture. This may do where a considerable portion of a house is devoted to the cultivation of some particular species or variety of plant, as with those who grow certain things in quantity for market; but, even where such is the case, it does away with the possibility of removing any portion for retarding or accelerating the blooming as may be found desirable. The system has also another and serious disadvantage, that it prevents the plants being moved, to be dipped or washed by syringing for the destruction of insects, which must necessarily be dealt with by hand, causing much greater expenditure of labour. Neither is there anything gained by planting out in this way, as the plants, if well managed, can be grown quite as well and as quickly in pots. In a house of large dimensions planting out may be resorted to with good effect, so far as appearance goes; but the inevitable consequences are that a few of the strongest growers destroy all the others, and when any plant is out-growing its neighbours, there is no means of remedying the evil without taking up and re-planting, which in many cases, when the plants have become large, means nothing less than their destruction. The position which the gardeners of this kingdom hold, so far in advance of those of any other country in the cultivation of plants, is owing to the great superiority they have attained in the individual culture of each and all of the immense number of species and varieties grown, and not to the appearance produced by a crowded arrangement for mere effect, such as is seen in Continental plant-houses, whereby the health and general character of nine-tenths of the plants grown are completely destroyed. Long may it be before plant-growing in this country is reduced to the production of an assemblage of starvelings that will not bear individual inspection. An arrangement equal in appearance to planting out may easily be effected by growing the plants in pots or tubs, and plunging them in a bed prepared for the purpose. In this way they have just the look of being planted out, with none of the objectionable consequences attached to that system; there is also the great advantage derived from the plunging, that the whole arrangement of the house can at any time be altered by a different distribution of the plants, that breaks the monotony of seeing them always in the same position. Where anything of this nature is carried out, it of course implies that the use of stages or centre pits is altogether dispensed with. There is one difficulty attending the cultivation of stove plants; this is the rapidity with which the worst species of insects increase on them. This arises from the warm, genial temperature so conducive to the development of insect life, especially scale and mealy bug. Where the latter exists in a collection of stove plants, it is impossible to grow many of the finest kinds to a size and condition that display their true character, except at serious expenditure of labour. Nothing less than the complete extinction of this pest should suffice; and all other insects ought never to be allowed to get to any considerable head. This is alike essential to the health and to the appearance of the plants, and to the reduction of the labour in the destruction of the pests. The soil required for growing stove plants should always, as applied to both peat and loam, be of a good description, containing plenty of fibre. This is necessary, as the amount of water requisite for the greater portion is such that decomposition of the vegetable matter contained in the soil is very rapid, which also necessitates the presence of sand in sufficient quantities amongst the soil to ensure porosity. In potting stove plants there is one point that should never be lost sight of; it is that the soil, before being used, ought always to be placed where it will become as warm as the temperature of the house in which the plants to be operated upon are grown. When the soil is used in a cold

state it necessarily chills them, at a time when they are least able to bear it, when their roots have been more or less broken in the operation of potting. Most stove plants, on account of their rapid growth, need, when in an active state, a large quantity of water; some require to have the soil always kept somewhat moist; others, when at rest, want drying off, and should receive, for a considerable time, very little. At no season of the year, or under any conditions of the plants, ought water to be given in a cooler state than the temperature they require to be grown in; and all through the growing season it may, with very great advantage, be applied considerably warmer than the temperature of the house they occupy. Although the majority of flowering stove plants enjoy all the light it is possible to give them, yet many will not bear the full power of the sun; it consequently becomes necessary to resort to shading; but, this should always be of such a character as to be easily moved when not required, for, on no account should it be over the plants when the sun's rays are not sufficiently full upon the glass to require their partial interception. Fixed shading ought always to be avoided, however thin the material used may be; for when the sun is not on the glass, it obstructs light. When blinds on rollers are used, these should never be let down earlier in the day than needful, or remain on after they can be dispensed with in the afternoon. From the widely different conditions under which plants that are usually brought together in a stove exist naturally, it is obvious that any method of treatment that is not considerably varied to meet the requirements of particular species, is not calculated to ensure success. It is from the adoption of an insufficiently discriminate system of culture in the plants under notice that many who attempt their cultivation only partially succeed.

In the plants hereafter to be treated upon, I shall endeavour, as clearly as I am able, to point out the individual requirements of each species and variety, with the particular purpose to which they are best adapted, whether as roof climbers, trained pot specimens—large or small—for general decorative use on the home stage, as also for exhibition, if required.

T. BAINES.

Gesnera cinnabarina for Winter Decoration.—Some fifteen years ago we had occasion to recommend this *Gesnera* as a most useful winter-flowering plant; and as an ornamental foliaged plant it is most effective up to the time of its blooming. We again referred to it recently as being very telling in combination with *Caladium argyrites*, all through the summer and autumn. It is to us a wonder that so charming a plant, and one so easily managed, is not more generally grown. A single bulb of it can be grown in a 6-inch pot, to a specimen 2 feet in diameter, and its orange-red flower-spikes are very striking, rising from its singularly rich and beautiful leaves. As a table plant associated or alternating with such as *Azalea Iveryana* in November and December, it is most effective, and candle light brightens up the richness of its foliage. It thrives best in a mixture of fibry peat, and in its early stages of growth it does not need very much water; but when the pots become full of roots it can scarcely be over-watered, for in a small pot it produces a great mass of leaves and bloom-spikes. Mixed on benches in the stove with light *Calanthes* or *Eucharis*, it is most effective.—“The Gardener.”

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Roman Hyacinths.—We have now had for some time past fine patches of the white variety of this *Hyacinth*, which, when intermixed with *Tulips*, *Heathes*, *Cinerarias*, and, above all, with *Epiphyllums*, produce a pretty effect. The blue kind is not worth growing.—R. G.

Camellia Saccii nova.—I find this *Camellia*, which is sometimes grown under the name of *Angustina superba*, to be an exceedingly free flowerer; its blooms, which are of medium size, are well formed, and of a delicate rose colour, and they are produced on the same plant for a long time in succession.—J. MITCHELL.

Phalanopsis from Seed.—Will any correspondent of THE GARDEN inform me if they have been successful in raising seedlings of these plants from seeds ripened in this country? They seed as freely as any plant either crossed with another variety or set with their own pollen, but the seed fails to germinate, although the seed-pods ripen off and burst open apparently quite mature.—J. G.

Begonia insignis for Winter Decoration.—This is one of the best of winter flowering *Begonias*. Cuttings of it struck in March, and grown on through the summer, in a temperature ranging from 60° to 70°, with an occasional application of Standen's manure, flower profusely during the dull months. The delicate pink flowers of this variety, mixed with blossoms of other shades, have a pleasing effect in the conservatory.—W. M. STICKLAND.

PLATE II.
NEW FALSE ACACIAS.

(ROBINIA PSEUDO-ACACIA.)

ONE of the most useful trees ever brought to Europe is the common False Acacia, now as well known as it is useful. Of all other trees it is the last to retain fresh green leaves in the streets of London, and it is the only tree that has been found to stand the blazing heat of summer in the streets of Constantinople. Old trees of the False Acacia in the parks and pleasure gardens of England, as, for example, at Pains Hill, have a singularly picturesque appearance. It is, however, too well known throughout Europe to render it necessary for us to add to the many writings already published concerning it. We desire rather to call attention to the remarkable new varieties of this fine tree now in cultivation. Of these, one of the most remarkable is *A. Decaisneana*, which we now figure, and which, as will be seen, is quite distinct from the species, as regards the beauty and colour of its flowers. It is a vigorous grower, with rather an open habit. For ordinary planting, perhaps, the best of all is *A. Bessoniana*, a kind with fine dark foliage, largely grown by Mr. Anthony Waterer, at Knaphill. It is a vigorous tree, with a rapid habit of growth. In addition to these, there are the weeping variety, called *pendula*, and also the weeping-leaved variety, named *pendulifolia*, both ornamental kinds; and, also, the large-leaved sort, called *monilifera*. There is, too, the very remarkable pyramidal variety, named *pyramidalis*, of which fine specimens may be seen growing by the sides of the flower walk in Kensington Gardens. This has the habit of a Lombardy Poplar, and is not nearly so much planted as it ought to be. Of these Acacias, M.M. Simon-Louis, Frères, of Metz, have a remarkably fine collection, particulars of which we hope to furnish on some future occasion.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sowing Peas.—In all parts of the country where the soil is not more than ordinarily cold and retentive, and consequently not adapted for producing early vegetables, some Peas should now be sown. This is necessary even where those sown in November look promising, inasmuch as should they fail a delay in the supply will be the result. Even where the ground is naturally dry, it is necessary at this early period to sow much shallower than later in the season, for if the seed is covered too deeply it is certain to perish, more or less, should severe and continued frost or much wet set in. The trenches ought not to be made above 2 inches in depth, and over the soil above the Peas put a couple of inches of coal ashes; this will not only protect the Peas from frost, but will prevent slugs from penetrating the ground and eating the young sprouts before they appear on the surface. Mice are also often troublesome in the case of early sown Peas, doing much mischief, in spite of all attempts at trapping them. As a precautionary measure nothing is more effectual than finely-chopped common Furze (Gorse) scattered about an inch in depth over the Peas in the trench and immediately in contact with them under the soil; through this mice will not burrow. For present sowing there is no better Pea than William the First, which should be sown in rows about 3 feet apart. This is certainly the most economical distance, inasmuch as it allows Spinach to be sown between the Peas later in the season. The Peas ought to be sown much thicker now than in spring, when they are less likely to rot. For this early sowing, if the land is of a damp character, it should be formed into ridges running east and west, 18 inches wide at the base and a foot wide in height; the Peas should be sown on the south side of these about half-way up, and covered as advised in the case of those in trenches. Thus treated the seed lies drier than it otherwise would do. In all cases the ground should be moderately rich, either by sowing after a crop that has been well manured, or by a special application for the Peas.

Broad Beans.—Where these are required an early sowing should also now be made; they succeed best in stiff soil, provided it is not wet; they are not an exhaustive crop, and consequently do not need very rich ground; they may, with advantage, follow any other vegetable that has been moderately manured last year. Sow, in double rows, 12 inches apart, the Beans being 6 inches asunder in the rows, with 2 feet spaces intervening. Cover the seed with about 2 inches of soil

and an inch or two of ashes. The Early Long Pod is a good Bean for this sowing, and a free cropper. In localities where the land, even when well drained, is cold and late, it is better to defer sowing both Peas and Beans for some weeks yet, as, when the seed lies dormant long for want of sufficient heat in the soil to cause it to vegetate, it becomes weakened, and, under such conditions, more is lost than is gained by early sowing.

Radishes.—A bed of Radishes should now be sown, choosing a warm sunny corner for the purpose. For these the soil should be rich, as their quality is much improved by quick growth. In digging ground for Radishes, break the soil quite fine, and at this season sow moderately thick, as the plants, when necessary, can be thinned out afterwards; rake the seed evenly in, and then cover with half an inch of fine soil, such as old potting material or that used last summer in the Cucumber or Melon frames; over this place a couple of inches of litter, on which put some straight Pea sticks to prevent the straw being blown about. Early Frame or Short Top Radish is the best for present sowing.

Potatoes.—Amateurs who do not even possess a supply of hot manure, or other fermenting materials, whosoever to grow early Potatoes can by a little forethought have them quite a month sooner than they otherwise possibly could, by placing over them a slight inexpensive frame formed of inch-boards, protected overhead by bast or straw mats. A frame of this description 10 or 12 feet long, and 6 feet in breadth, will bring forward a quantity of Potatoes that will be found most acceptable before they come in from the open borders. For planting under such protections, select an early kind, such as Myatt's Ashleaf, Mona's Pride, or Hammersmith Kidney, all of which are both early and good kinds. They should be placed at once in a shallow box, 6 or 8 inches in depth, in the bottom of which should be put a couple of inches of fine soil. On this set the Potatoes, sprout end upwards, and fill the box, so as to keep them in position. Then place them under a greenhouse stage, where, if possible, they will get a little warmth; but where that is not available, place them in a warm room. A mat, or other covering, to exclude light, should be laid over them until they begin to grow; after which they should have plenty of light to keep the sprouts stout and strong. Thus treated, they will come on quicker than they otherwise would do; and in order to encourage the sprouting, occasionally sprinkle them with water, so as to make the soil a little damp. Some weeks hence, when the sprouts have got 2 or 3 inches long, they can be planted out. Potatoes, for planting in the open ground, should also be laid singly, where they will get plenty of light; for, if kept in the dark, the sprouts grow so long and weak that they are certain to get broken off at planting time, an occurrence which weakens them greatly, and retards their coming to maturity by several weeks. Any of the Kidneys just named, together with a few of some early round kinds, such as Early Handsworth or Early Oxford, to come in first, relying for the principal supply upon the yet unsurpassed Regents and a few of Paterson's Victoria for the latest after the Regents begin to get soft, will give more satisfaction than growing a host of varieties that have little or no satisfaction than beyond novelty. All the Potatoes intended to be planted cannot be too soon got in, and treated as above advised. By planting early and second early kinds, properly prepared for the principal supply, not only are the chances of securing sound crops increased, but an advantage is gained in getting the ground cleared for planting with winter vegetables, that will have time to grow to a useful size.

Planting Hedges.—If any hedges have yet to be planted, the work should not be longer deferred, as upon its early completion, in a great measure, depends the progress made in growth during the ensuing summer. In planting garden hedges, either for shelter or fences, the chief object is to get them up as quickly as possible; to ensure this, the first thing to be done is, if the land is wet, to put in a drain parallel with, and at a distance of 5 or 6 feet from where the hedge is to stand; the ground should then be well dug, and plenty of manure added. For a fence nothing is better than Quick Thorn, and for appearance nothing is superior to Holly. If Thorn is used, in selecting the plants, do not be guided by size so much as by an abundance of roots, which can only be had in the case of plants which have been transplanted whilst in the nursery; as often as they require it. Put the plants in double rows, 12 inches asunder, a foot apart in the row, and by no means be induced to follow the barbarous practice of cutting the heads off previous to planting, under the impression that time will thereby be gained. This kind of decapitation has the opposite effect, and that to a serious extent; let them grow for a season, and then head them down. Treated in this manner, at the end of three years they will be double the size of those beheaded before planting. To those who have not had experience in this sort of work it may be necessary to say that this cutting back is to induce the plants to make a bushy close bottom. Where Holly is planted the work should be deferred until April. There is no

THE ROSY LOCUST TREE *ROBINIA PSEUDACACIA DECAISNEANA*.

worse time in the whole year for moving plants of this description than the present. The distance apart at which Hollies for a hedge should be planted depends upon the size of the plants; when of the ordinary trade size, sold for such purposes, 15 or 18 inches will be the right distance asunder in a single row. When a hedge is required for a screen or for shelter, but not as a fence to turn cattle, there are few plants equal to the oval-leaved Privet, the rapidity of the growth of which in good rich soil is surprising. In five or six years, if well attended to, Privet will form a perfect hedge 7 or 8 feet in height. If required for dividing a kitchen garden from a pleasure ground or similar purpose, a Rose hedge is both appropriate and has a good effect when in bloom. Any strong-growing, free-flowering variety or, still better, varieties may be used; they should be on their own roots, the ground heavily manured, and planted at once.

Indoor Fruit Department.

Vines.—Vine eyes should now be put in, and they should be selected from the firmest looking upon the wood which has been saved. The thickest wood does not always produce the finest canes, and it frequently does not start into growth so freely as that of medium strength. For starting in pots, the eyes require to be made in a different manner from those intended for striking in beds of soil. In the first case the wood should be cut close above the bud, leaving 2 inches below it, the cut being made in a slanting direction about an inch in length, and a small notch should be made on the side of the wood opposite the bud. For placing in beds of soil the slant cut should be made at both ends, as the longest one has been for pot propagation; the wood should extend an inch and a-half each way from the bud, and both ends must be made slanting, a sharp knife being used in the operation, or the wood may be injured. Pots of the 4-inch size should be used; they should be quite clean and thoroughly drained with small crocks, and must be firmly filled with good fibrous loam, and no other ingredient should be used. Rich manure is not favourable to the production of healthy roots, and when used to any extent the soil has a tendency to become sour before root action begins. As each pot is filled a hole should be made in the centre with a dibble sufficiently large to admit the cutting, which should be pressed in with a little silver sand around it. The whole should then be watered through a fine rose, and allowed to remain on the potting bench, or some similar place until the time arrives for placing them in heat. Those intended for beds of soil cannot be placed there at present, but should be put into a mixture of loam and sand, and treated in a similar way to those in pots, when they will form a callus, and root freely after being transferred to their growing quarters.

Pines.—As the root soil of recently started Queens should now be damp enough to start the fruit, do not give much more water until it appears. The object of this is to get the fruit on before the plant grows too much, as a rank growth is often unfruitful. As the days lengthen give a little more air on every favourable opportunity to all Pines. Suckers in small pots, which will be re-potted in the course of a few weeks, may have the heat increased 5°, and be given a little more water at the root, that they may be in a slightly growing state when they are shitted.—J. MUIR.

Hardy Fruit.

Where summer pruning—that is, disbudde, pinching, or stopping the shoots—is regularly practised, little, if any, winter pruning is required. For established plants of most kinds of fruit summer pruning is the most natural way of inducing fruitfulness, as, by it, growths that would otherwise develop into gross shoots with wood buds only, are, by the check which they thus receive, made to form fruit buds; and, at the same time, the necessity to root-prune is reduced to a minimum. Unfortunately, however, for the full application of this principle of pruning, there are at that period so many operations claiming attention that time cannot be found to keep pace with the growth of the trees; where, therefore, such was the case last summer, let all pruning required be done forthwith, beginning with Apricots, as these are the earliest to flower. In pruning avoid all unnecessary amputation of large branches, and other injuries to the wood or bark, and remember that nothing is gained by laying in the shoots too thickly. Planting of every kind of hardy fruit trees should now be completed as soon as circumstances will permit, and the variety to be planted should be well considered. There are now so many good kinds, that it is not worth while to plant uncertain ones. When the ground is hard through frost, and planting is out of the question, soil for the purpose may be prepared, and wheeled into position, in readiness for use when favourable weather sets in. Stakes may also be cut for newly-planted trees; and any that are rotten, in the case of espalier-trained trees, may be renewed, i.e.,

when proper espalier fences are not used. Manure may likewise be wheeled ready for mulching purposes. Strawberries should have the first attention in this respect, provided they were not mulched, as has been recommended, in the autumn. Orchard trees and Nuts may also furnish employment in bad weather, the former by clearing them of Lichen and Moss, and dressing the stem with quicklime or brine; the latter by removing suckers, and regulating the branches. Birds are already becoming troublesome; and, if not watched, and means of prevention adopted, they will soon relieve Pears, Plums, and Gooseberries of all their fruit buds.—W. WILDSMITH, *Heckfield*.

Conservatory.

Except for the purpose of expelling damp, very little fire heat will be necessary while the weather remains in its present mild state. Should fogs or wet prevail so as to cause a moist state of the atmosphere, a little air should be admitted by the ventilators while the fires are going, so that any excess of moisture inside the house may be driven out instead of condensing on the flowers. Any superfluous growth in the roof climbers should be at once cut out, so that all the light possible may be admitted at this dull season. Fresh plants should be admitted as others go out of bloom, and occasionally an entire re-arrangement should be effected, so as to give fresh interest. This may sometimes be desirable even while the house is still gay, as plants, seen under the same conditions day after day, soon cease to be as attractive as they were at first. Richardias are exceedingly useful at this season; and, by introducing a few into heat as occasion requires, a regular succession of their highly esteemed flowers may readily be kept up till quite late in the spring. A few plants of these always produce a very pleasing effect when placed amongst others, so as to allow their stately foliage and flowers to stand prominently out. Where sweet-scented flowers are prized, Heliotrope is sure to be in request. Any old plants that were saved in the autumn may be soon had in bloom by subjecting them to a gentle heat of from 50° to 60°. In doing so they should be kept well up to the glass, so as to enjoy every ray of light, or the flowers will be defective both in colour and form. Mignonette is a special favourite at all seasons, and particularly so just now; a dry atmosphere, a temperature of about 45°, with plenty of light and air, will ensure having this in the greatest state of perfection all through the winter. See that it does not become dry at the roots or the under leaves soon turn yellow. On the other hand, it must not be kept too wet, as it is very impatient of excess of moisture and soon dies off. Clear soot water is the best stimulant for this plant, and imparts a healthy deep green tinge to the foliage. Any in bloom or approaching that period of its growth will be greatly benefited by an application of this whenever watering is necessary. In the greenhouse, Azaleas, Acacias, Epacris, and other plants subject to trips or scale should now be looked over, and receive a thorough cleansing. For scale, a solution of Gishurst's or Fowler's insecticide, in the proportion of from 4 to 6 ounces to a gallon of water, will be necessary. Where many plants require the application of this solution, a sufficient quantity should be made, so that the heads of the plants may be immersed, after which they should be laid on their sides to drain, care being taken, at the same time, that none of the solution is allowed to soak into the soil round the collar of the plant. Trips is the most troublesome insect to Azaleas, and, if allowed to get established, it soon cripples the plants, and renders it difficult to get them into a satisfactory condition afterwards. It is almost useless attempting to reach these by fumigating, as they are securely hidden around the flower buds and under cover of the close-lying leaves that enfold them. Even if it were possible to reach them with tobacco smoke their eggs would be uninjured by its fumes, and these, hatching in the spring, would soon re-stock the plant. This being the case, several dippings in strong tobacco-water will be found the most effectual. A pound of tobacco soaked in 2 gallons of boiling water to which 4 ounces of Gishurst's or Fowler's insecticide has been added, will make a wash sufficiently strong for the purpose. By holding the heads of the plants over a large tub while they are being syringed with the liquid, the greater portion of it will be caught, so that it can be used several times over. In this way a large number of plants can be wetted without much expense being incurred. See that every leaf is reached by the liquid, and then leave the plant to drain, so that it does not run into the soil. Repeat the wetting at the end of a week or so to ensure a thorough cleaning.—J. SHEPPARD.

Stove Ferns.

At this season of the year most of the fronds of stove Ferns are in a thoroughly mature state; and, consequently, in a better condition to withstand the effects of fumigation or the application of any insecticide that may be found necessary to rid them of scale, to which, unfortunately, some of them are rather subject. This is especially the case if any of the varieties happen to be in a higher

temperature than they require. Thrips generally attacks the broad-leaved varieties, such as the *Neottopteris Nidus*, *Blechnums*, *Lomarias*, and others of that class; and, if allowed to effect a lodgement, they soon cause a good deal of disfigurement, that cannot be effaced till a fresh growth takes place and admits of the old fronds being removed. Therefore, the whole stock should now be looked closely over to see if any are at all infested by these pests, and, if so, they should at once be fumigated, the same operation being repeated at intervals of a few days till the insects are completely destroyed. Many of the more tender varieties are easily injured by tobacco smoke, and, therefore, any that are clean and do not require to be subjected to it, should be removed from the house. *Adiantums*, perhaps more than any other plants, are most susceptible of injury in this way; and, as they are rarely attacked by thrips, it is seldom necessary to run any risk by allowing them to remain with the others while fumigation is going on. The turtle or brown scale is the most troublesome insect to which Ferns are liable, and nothing but careful hand-washing with a sponge and suitable brush will be found at all effectual, as any insecticide solution made strong enough to destroy the scale by dipping the plants would, in all probability, kill or injure the fronds. Keep all quiet and resting for some time longer by having the temperature within bounds, ranging from 50° to 60°, according to the state of the weather. Very little atmospheric moisture will be sufficient just now, and this may be got by damping the floor and other cold surfaces, but avoid steaming the pipes. Tree Ferns that are getting too high and push their fronds against the roof, or that are too redundant in growth to be confined to the spaces allotted to them, may, with safety, have their stems shortened to the desired height, and a portion of their old fronds cut off, which will greatly check any tendency to strong growth for the next year at least. Where it may be found desirable to shorten the stems a few of the old fronds should be removed at the same time; and, after the trunk is again re-planted, both it and the remaining fronds should be kept well syringed. Should the trunks not have made plenty of roots round their sides, it may be necessary in some cases to bind them up with Moss to induce them to do so.

Greenhouse and Half-hardy Ferns.

Many of the remarks made with regard to the stove varieties, as to insects, cleaning, fumigating, &c., are applicable to these also. Most of the viviparous varieties will be found to be carrying numbers of minute plants on their fronds. These may now be taken off and placed in pots in a close moist place, where they will soon emit roots, and form fine plants. *Woodwardia radicans* bears a plant at the end of almost every frond, and although these may not be required for indoor cultivation, the whole should be saved, as it is one of the grandest Ferns it is possible to have for planting in the hardy Fernery, where it stands well with only slight protection. Little remains to be done in the hardy Fernery just at present beyond seeing that all of doubtful hardiness have the necessary protection to carry them safely through the winter. This is most readily afforded by a thick layer of fresh fallen leaves, such as Oak, that will lay and keep well together. An evergreen branch or two, or some dry Fern fronds will ensure this. Planting, except for the very strong and robust kinds, had better be deferred for the present, and even these may with advantage be left till March.

The Hardy Fernery.

The site for this should be well sheltered, both from winds and sunshine. A dell, hill side, or sloping bank, dipping to the north, north-east, or north-west, affords the best situation, and, if overshadowed by deciduous trees, standing at a distance, so that their roots do not intrude and rob the soil of its moisture, the spot will, in every way be favourable to grow any of the hardy Ferns to perfection. Anything approaching to rock-work had better be avoided, unless it can be well carried out, as any attempt to imitate Nature, without incurring considerable cost, must have a very puerile appearance, and end in utter failure. If rock or stone-work is used at all, it should be in the shape of huge boulders, jutting out here and there, that they may have the appearance of cropping up naturally. Stones piled up are not rock-work, nor in any way an imitation of it, and, unless for the purpose of burying up, so as to add to the moisture and help to keep the irregular-shaped mounds or steep banks in position, they had better be left out altogether than be used in an objectionable way. Where a hill side having the proper aspect is not available, large irregular cuttings should be made, and the soil that has to be thrown out can be used on each side, to give increased height to the banks, which should be as broken and rugged as possible. For the sides to maintain their position, the inclination of the soil must not be too steep, and any stones buried may be made of use to prevent it slipping. In making the cuttings so as to form the various banks and mounds, they should be made of great width, so as to leave plenty of room to

face all over with a good thickness of suitable soil in which to grow the Ferns. Taking into consideration the space required for these to grow and spread their gracefully-arching fronds, and the depth of good soil necessary to grow them to perfection, the width of the cutting at the base should be at least from 10 to 15 feet. If water is not present, it may be introduced or brought as near as possible, for without abundant supplies of this during dry weather they will not long maintain that luxuriant growth, or remain in the fresh, healthy condition for which Ferns are so much admired. The soil most suitable for hardy Ferns is a good yellow loam, such as may be obtained by digging the top soil of any old pasture. To this add a third of good peat, leaf soil, trimmings of banks, or any gatherings of that kind that are rich in vegetable matter.

Halls and Corridors.—Select for situations of this kind any plants of bold type, having thick leathery leaves, such as *Aralia Sieboldii*, *Ficus elastica*, *Aspidistra lurida* and its variegated variety. The beautiful silvery green and handsomely cut leaves of the *Melanthus* major, reader that one of the most valuable plants for associating with those mentioned above. Large plants of *Echeveria metallica*, with their glaucous rigid looking leaves, are very suitable for decorating halls and corridors, as the absence of light, and the dry atmosphere of such situations has but little effect on them, unless kept there an unreasonable time.—S. W. P.

Floral Decorations.

To those who have stove and greenhouses from which to cull, and to those who have access to Covent Garden Market, and have the means wherewith to purchase what they fancy, the following lists will be of little service. There must, however, be very many readers of THE GARDEN who are denied such privileges as these, and who are obliged to leave it to others to select for them, or who have to write out a list of their wishes, which they may often do without feeling at all sure that they can have what they propose to ask for. To them it will be serviceable to have the opportunity of referring to the first number in each month of this paper, wherein they will find lists of the principal flowers and coloured fruits which are obtainable during that month for decorative purposes: It is believed that the usefulness of these lists will be much enhanced by classifying the flowers and fruits according to their colours; so that either contrasts or harmonies may be carried out at pleasure, whether it be for vases, bouquets, head-dresses, or any other application of flowers ornamentally. It must not be supposed that these lists have any pretensions to completeness—many rare flowers, such as *Orchids*, are yearly becoming commoner; some common flowers, particularly annuals, such as *Nemophila*, *Mignonette*, *Rhodanthe*, &c., are often to be met with at unseasonable periods; to these no reference is made because a supply of them cannot be depended upon. Notwithstanding these omissions, there will, I think, be found sufficient variety, even in the winter months, to prevent anyone in future from asserting that there is "nothing to be had." It should not be forgotten that some of the prettiest arrangements are made out of "nothing," i.e., "nothing particular." The following are procurable in January:—

Blue—Hyacinth and Siberian Squill.

Purple—Heliotrope, Hyacinth, and Violet.

Mauve—Heath and Tulip.

Pink—Begonia, Bouvardia, Camellia, Carnation, Chinese Primrose, Cyclamen, Epiphyllum, Fuchsia, Heath, Hyacinth, Rose, Tulip, and Zonal Pelargonium (single and double).

Crimson—Camellia, Cyclamen, Epiphyllum, Fuchsia, Hyacinth, Poinsettia, and Rose.

Scarlet—Bouvardia, Carnation, Fuchsia, Tulip, Zonal Pelargonium (single and double), berries of Cotoneaster, Holly, Solanum capsicastrum, and Euphorbia jacquiniiflora.

Orange—Carnation, Rose, and Tulip.

Yellow—Carnation, Rose, and Tulip.

White—Andromeda, Azalea, Bouvardia, Camellia, Carnation, Chinese Primrose, Cyclamen, Eucharis, Gardenia, Heath, Hyacinth, Irish Heath, Lilac, Lily of the Valley, Paper-white Narcissus, Roman Hyacinth, and Stephanotis.

—W. T. T.

Market Gardening.

Out-door operations must necessarily depend at this time of the year upon the weather. The main point to be kept in view is to be always ready to take advantage of favourable opportunities, endeavouring, as much as possible, to make work and weather harmonise. Nothing is to be gained by setting men to any kind of work that entails unnecessary exposure and discomfort to them, for the time spent in attempting to beat warmth into the chilled body and benumbed fingers will always be more profitably employed by a good manager. To set men to such work as pruning, nailing, &c., in very cold weather can only result in dissatisfaction to the men

and loss to the employer; but, with proper management, no time need be lost—wet, snowy, or dry frosty weather may all be utilised. Wet days should be provided against by always having indoor work ready for men to go to, and much of the outside labour may be forwarded under cover; it makes a vast difference in the amount of work to be done on fine days, when materials of all descriptions are ready to hand, properly prepared for use. Large stakes, for the support of young fruit trees, of which some are certain to be displaced by the winter storms, and sticks of various sizes should be cut and tied up in bundles, with a proper supply of tar string, twine, wire, &c. The French employ a great quantity of lead wire, which is very convenient to use, being pliable and easily broken between the finger and thumb. Labels of all kinds, both for inserting in the ground and for hanging on trees, should be made and painted, the latter wired, as twine soon rots. If clay is employed for grafting, a portion may be got in and prepared, as it can hardly be too much beaten. Putty should be made, for glass is sure to get broken in covering, and nothing looks more deplorable than rows of frames with shattered panes, which allow the heat to escape and moisture to enter. Seed Potatoes should be frequently looked over; those who have convenience for laying them out thinly in a dry, light, airy place, have the advantage of not being obliged to plant quite so early. Short, green, spur-like shoots, with the rudimentary roots being formed, and ready to grow as soon as set are best. Kidney Potatoes are much benefited by this treatment; there will be no blinks, and they come up much stronger if this system is followed. If covering is required for frames, straw mats should be made, a supply of hand-threshed rye-straw being in readiness; a good straw-mat will keep out 15° degrees of frost, is quickly put on and removed, and, with proper care, will last several years. I find that the materials cost about a halfpenny the square foot; women and boys can make them, and if constructed like the French paillassons, they have an extremely neat appearance. I should like to see them much more extensively employed in this country than they are. A general review of the seed stock should be held, the amount of each kind required calculated as nearly as possible, and where any deficiency occurs the needful supply should be at once laid in. Small seeds should be carefully cleaned, neatly put up, plainly labelled, and all put away carefully, but so as to be found at a moment's notice. Let tools of all kinds be looked to, and where any repairs are required, they should be done at once. Water-pots should be painted inside with a thin coat of red lead, and the bottoms outside coated with a mixture of tar and pitch or varnish. Take advantage of dry frosty days for carting and wheeling manure, trenching, and digging. Trenching is always better done than in wet weather, when the top spit often becomes trodden into hard lumps. Strawberry plantations that have not been dressed should be forthwith operated upon; worms and the rain will work the manure well in before the approach of spring. All spare pieces of ground should be thrown up well into ridges, and the larger the lumps the more thoroughly sweetened will it become. Old fruit trees ought to be looked to, the moss cleaned off, old wood cut out, and the younger subjects judiciously thinned. Young plantations will also require some supervision, and all kind of pruning should be finished as soon as possible. Put rubbish of all descriptions together to decay, and have old compost heaps turned over in frosty weather. Lettices and Cauliflowers in frames need constant care and plenty of air, dry ashes or sand being dredged upon the soil to keep down damp. Some boxes of Lettuce may be sown in gentle heat to be afterwards pricked off. This sowing is often found extremely useful. Select the driest and most sheltered situations for Peas, Beans, and early Radishes, paying special attention to the covering of the latter during the earlier stages of their growth; with care, this crop may be made very profitable if a little extra time and labour be expended on it.—JOHN CORNHILL, *Duffield*.

Church Decoration.—Allow me to acknowledge the assistance and benefit which I have derived from Miss Hassard's excellent hints in reference to "Church Decorations at Christmas." One fine old church at Whalley, in Lancashire, has a venerable history; portions of the present edifice date from the fourteenth and fifteenth centuries; the arches of the nave are in the decorated style of architecture, the under portion of the span being flat. For these we adopted Miss Hassard's suggestions of bands of wood covered with scarlet, and Holly rosettes and red berries placed at equal distances. In the recesses at the base of the chancel windows we put fresh Moss, and, in the centre of each, tins of different designs containing natural flowers and Ferns; these have been much admired, appearing, as they did, behind the dark Oak stalls of beautiful "perpendicular" work, the latter having been removed from the adjoining Abbey when the Conventual Church was destroyed.—M. L. W.

THE FRUIT GARDEN.

RESTRICTION v. EXTENSION OF FRUIT TREES.

On a dry bottom, with a good depth of suitable soil, and favoured as regards shelter, fruit trees of all kinds may be allowed to extend themselves with advantage. There is, and must always be, an evenly maintained balance between root and branches. If the roots are growing in a cold wet soil, its effect is soon seen in the shape of watery unripe wood. On the same principle, anything that checks the growth of the branches, such as attacks of insects, or extreme exposure to cold cutting winds, reacts prejudicially upon the action of the roots. I remember, some years ago, that a very thriving orchard was completely ruined by cutting down a belt of trees, in order to open up a vista. The cold wind being let in checked growth, chilled and destroyed the blossoms, and, one by one, the trees actually perished, and had to be removed. This may be an extreme case; but in some districts, shelter is absolutely necessary for the attainment of success in fruit culture. Under favourable circumstances, as to soil, climate, and shelter, the fruit grower's difficulties are reduced to a minimum; and any cultivator who has spent most of his time under such conditions, and noted the advantages of a natural system of management, may well be excused if he looks upon all forms of restriction as barbarous. Whilst the cultivator who has been all his life battling with adverse circumstances comes to the conclusion that a system of restriction is the very perfection of fruit culture, errs in the opposite direction. There is, however, no doubt that, under favourable circumstances, very profitable results in the culture of all kinds of fruits have been obtained by allowing the trees full and free development. In the case of Vines, Figs, and other kinds of fruits, I have often noticed the advantages of allowing a healthy, vigorous tree to extend itself, even if, by so doing, it was necessary to remove a weaker neighbour. This, in fact, under the conditions I have named, is only giving effect to an acknowledged law of Nature, which secures the survival of the fittest to fill the place. On the other hand, however, in the case of soils not so favourable for fruit culture, it has been found necessary to adopt a modified form of restriction by using dwarfing stocks for grafting on, by root-pruning, and by a close attention to summer pinching, and I am of opinion that this latter process is deserving of far more attention than it generally receives. That it is sometimes carried too far I will not deny; but it is far oftener too little attended to. In summer pinching, the age and condition of the trees should be first considered; if a vigorous young tree is pinched in too closely, there will be no fruit, as the back eyes will break into growth, instead of maturing blossom buds. To successfully manage fruit trees on the restrictive principle requires more skill and a higher order of intelligence—if I may so express it—than when growth is allowed to go on in a more natural manner. The truth is, that under any system of restriction the conditions of growth are more artificial than under other circumstances; increased care and attention are, therefore, required, in order to maintain an exact balance between roots and branches, without having much recourse to the pruning knife; keep the wood properly thinned out and pinched back, according to the strength and vigour of the tree, and expose, in fact, every leaf to the influence of sun and air. This will thoroughly mature the buds, lay the foundation of fruitfulness, and, at the same time, make far less demand upon the roots than when multitudes of soft shoots are allowed to grow. When fruit trees are allowed to produce quantities of soft, useless wood, useless at least as far as fruit-bearing is concerned, the roots, unable to find the necessary supply of moisture near the surface are compelled to descend to a lower stratum for it, and then, in order to rectify this evil, it becomes necessary to have recourse to root-pruning. If summer pinching could be more sedulously attended to there would be less root-pruning required.

Ramsay Abbey.

E. HOBDAY.

The King Pine-apple.—An old Pine grower (see p. 507, Vol. VIII.) asks for information regarding the old King Pine. In the "Transactions of the Horticultural Society," second series, Vol. I., p. 7, I find it described as a smooth-leaved variety with green waxy leaves

entirely free from meanness. This Pine, according to Martin, in his edition of "Miller's Dictionary," was raised from seeds taken out of a rotten fruit, which came from the West Indies to Mr. Henry Heathcote. It is a very handsome fruit, of middle size, and generally weighs from 3 lbs. to 4 lbs., but is rather tardy in fruiting. The Pine-apple is a far more variable fruit than is generally imagined, and fifty-two varieties are described as distinct in the volume above cited.—B.

GRAPES COLOURING BADLY.

"K. K." (see p. 538, Vol. VIII.) will find that widening his Vine-borders and leaving his tap-roots in the sub-soil will be of little or no benefit to his Vines, and that if they are not worth cultivating properly they are not worth any trouble at all. Your correspondent should procure some good fibrous turf—if of a calcareous character, all the better—first mowing the Grass off close, and if the turf is in a dry state it should be used at once chopped up roughly, and mixed freely with refuse brick that has been broken up to the size of ordinary road metal. If oyster shells are obtainable, burn them, and they may then be used instead of bricks. When the material is ready, commence at the front of the border, removing all the soil with a fork, to the depth of the border, but taking care to preserve the whole of the roots, except those running into the sub-soil, which should be cut off, as low down as convenient, tying the others against the front of the Viney, protected with damp litter and mats. Then prepare the site for the bottom of the border, allowing a gradient from the Viney to the extremity of 1 inch in a foot, and cover the site over with 4 inches of concrete. A main drain, running parallel with the border at the front and 9 inches below the concrete, should be cut, and, at right angles across the border lines of 2-inch drain tiles should be placed 6 feet apart, filling carefully in between with refuse brick or stone. This will ensure perfect drainage, and carry off heavy rains or the water from overflowing spouts. Cover over the drainage with turf, with the grassy side down, and make up with the chopped turf to the depth of 3 feet close to the Viney, making solid, and allowing a good incline to the front, to admit of top-dressing, when required. Damaged portions of the roots should be cut off in a slanting direction, spreading out the rest straight, covering them with not more than 2 inches of soil, and the entire surface with 8 inches of fresh litter, laying wooden shutters over this. The border is thus protected from heavy rain and snow, and a gentle heat, produced from the decomposition of the green turf, which is congenial to the well-being of the roots, and prevents the Vines suffering from any check. All manure should be applied on the surface, the rain carrying it down by degrees, the border being thus kept in a sweet and healthy condition, and the Vines in a good bearing state for many years.

Waterdale.

JAMES SMITH.

"K. K." (see p. 538, Vol. VIII.) need not expect his Grapes to colour or ripen in perfection, so long as the tap and other roots are in bad soil. Had the border been rightly constructed at first with a layer of concrete at the bottom, the roots would not have got down into harm's way. As it is likely that there will be many roots emitted in the good material close to the surface which has been added, these should not be disturbed, if possible; but the tap root should be got at by digging a hole 2 or 3 feet from the stem, and tunnelling into it, when it should be cut at 2 feet from the surface, for the entire border could not be overhauled without destroying a great many roots, and giving a severe check to the Vines. Black Hamburgs frequently colour badly, from being overcropped; but, although lacking colour, they are often very sweet. Vines derive very little benefit from oyster shells in any form, and scallop-shells are no better; where the soil is very retentive, they help to keep it open; but, for this purpose they are no more effectual than small brick-bats or lime scraps. Half-inch bones may be used with greater advantage in Vine border compost than any other kind of material; half-a-hundredweight of them should be added to every cart-load of soil.

J. M.

NUTS AND NUT CULTURE.

To Mr. Webb, of Calcot, we are indebted for several improved varieties of Nuts, called Webb's Prize Cob Filberts, specimens of which we have seen, and know to be excellent. In a little pamphlet, published by Mr. Webb, in reference to Nut culture, he says:—Finding the demand for Cob Filberts increasing, in 1855 I planted all the ground I had (10 acres) with them, in the following manner:—I put my trees in squares, 8 feet 3 inches apart, and therefore it took 640 trees to plant an acre; now as my trees were getting to a good size, I planted Potatoes between them, and had a good crop on the same ground for seven years in succession, and only

manured once since the first planting, and over these I have Apple, Pear, and Plum trees, all in bearing order. Now if the 640 trees annually bear Nuts to the value of 1s. each, the amount will be £32 per acre per annum, and if they should produce to the value of 10s. each tree, it would bring in the almost fabulous return of £320 per acre. It is not, however, too much to suppose they will yield even more than that; and, as a proof of this, I had six people employed for a quarter of a day gathering the Nuts off one tree, and they were all witnesses to the weight, 110 lbs. of Cobs Nuts. Looking, then, at the price obtained in the market—always a sure one—and at the fact that they are certain bearers six years out of seven—I am of opinion that no crop can be planted which will yield so much money per acre. Let any man purchase 20 acres of land (for it should be freehold) at £100 per acre, and plant it with Cob Filberts; in seven years, it will be worth £1,000 a year to rent—to purchase, ten times the original cost. So certain am I of the correctness of this statement, that I have planted all the ground I have with these trees. Another circumstance is that these trees will grow on every soil, so that much of the waste land about Chobham and its neighbourhood would be a very profitable investment to purchase and plant. Some people are afraid of the expense, but they should, I think, also look at the returns, which are more than cent per cent., and the value goes on increasing year after year. If in America, an enterprising man were to get the grant of 1,000 acres, and at once clear and plant it with Cob Filberts, he would find it one of the most remunerative transactions of his life—their transit to this market is easy, and they are not injured from being two or three months in tubs, a circumstance which renders them as easy of carriage by land or sea, as flour. In Wales again, a quantity of waste land might be turned to good account if planted in this way; many parts also of Ireland and Scotland would be well adapted for such plantations if people could be found who would try; pay it would and that wonderfully well. The only drawback is the time you have to wait for the return, but even this is more than compensated for by the other crops grown on the land for the five or six years you have to wait, so that no time is lost. I say again, no investment can prove half so remunerative on almost every soil. I shall be happy to show my plantation to anyone who may wish to see it, and also to give any information I may possess on the subject. The land should, of course, be once dug every year, for the first seven years, and kept clean by hoeing, which will increase the fruitfulness of the plants, as well as their growth.

Particulars of Produce.

As regards the Cob Filberts, which constitute the foundation of these calculations, they have become a very profitable speculation, and to prove the fact I will now state the result obtained from parts of my plantation, which will be quite sufficient for our present purpose. Early in September we commenced gathering, and from half an acre of ground we had 1,300 lbs. of Cob Filberts, and also upon another three-quarters of an acre 1,700 lbs., besides Apples, Pears, and Potatoes, above and beneath. Let us first look at the value of the produce upon the half-acre where we began, viz.:

1,300 lbs. Cob Filberts, sold at £7 per 100 lbs.	£91 0 0
40 Bushels Apples	20 0 0
Potatoes	7 10 0

£118 10 0

This return is equivalent to £237 per acre. Again, the 1,700 lbs. on three-quarters of an acre, planted with Cob Filberts, actually sold at £7 per 100 lbs., and some at £7 10s. Let us, however, say

£7 per 100 lbs.	£119 0 0
50 Bushels Apples	35 0 0
20 " Pears	5 0 0
Potatoes	5 0 0

£150 0 0

Add one quarter more for the remaining quarter of an acre

39 15 0

Return per acre £108 15 0

I think, therefore, after many years' experience, that I am justified in anticipating what I have stated, that from £200 to £300 per acre may be easily realised in growing Cob Filberts and other Nuts of the best quality. I have left off digging between the trees for Potatoes, and now plant them on the top of the ground and draw the mould over them with a hoe; after being planted ten years in succession, I think my Cob Filberts will pay quite well enough without their assistance.

R. W.

Three Good Christmas Pears.—The three varieties of Pears in use here now (December 25th) are Passe Colmar, Eyewood, and Ne Plus Mourir, all of which are most excellent, Eyewood being, perhaps, the richest in flavour. Glon Moreau and Easter Beurré are fast approaching maturity. These two feast the eye as well as the palate.—R. GILBERT, *Burghley*.

TREES AND SHRUBS.

THE JASMINES.

THE genus *Jasmine* or *Jessamine* comprises a large number of evergreen, sub-evergreen, and deciduous shrubs, chiefly of a scandent habit of growth, natives of the south of Europe, many parts of Asia, and Africa. They are all very ornamental, and well worthy of cultivation for their handsome foliage, and beautiful, exquisitely fragrant flowers. From some of the species, particularly *J. officinale*, the well-known white *Jasmine*, a fragrant essential oil, is obtained in sufficient quantity to form an important article of commerce. Of the many known species, a very small proportion are sufficiently hardy for our climate in the open air; some, indeed, will only thrive in the stove; while the great majority require to be treated as ordinary greenhouse plants. There are several, however—and these not the least interesting and attractive—which may be classed among the hardiest of our ornamental shrubs; and of such we note the most distinct and desirable.

The Shrubby *Jasmine* (*J. fruticans*).—This species differs from most of its congeners in having a shrubby rather than a scandent habit of growth. It is an evergreen, or in severe winters a sub-evergreen, growing about 10 feet high, indigenous to a wide area in the south of Europe, and introduced to Britain about 1570. The leaves are trifoliate, the leaflets of an obtuse obovate form, arranged on the shoots alternately, and of a bright glossy green colour. The

The Naked-flowered *Jasmine* (*Jasminum nudiflorum*).

flowers, under ordinary circumstances, are produced very abundantly in June and July, are bright yellow, and borne in peduncles at the points of the branches. In our shrubberies it is a dense irregular bush, with numerous suckers from the root. When these, however, are regularly removed, and the plant is trained to a single stem, it forms a neat symmetrical specimen, well suited for a lawn or prominent position in the shrubbery border. From its liability to suffer damage from severe frosts, this fine plant should be planted in a sheltered situation. In the colder districts it is most commonly planted as a wall-shrub; and as such it has a pretty effect, rarely losing its leaves in winter, but growing luxuriantly and flowering freely year after year. It thrives best in a deep rich soil, and in a situation open to the sun.

The Naked-flowered *Jasmine* (*J. nudiflorum*).—This is a distinct and very interesting species, with a trailing habit of growth, the stems from 10 to 12 feet long, slender, very numerous, and much divided into small twiggy branches. It was first introduced in 1844 from the north of China, where it is not only found abundantly in a wild state, but extensively cultivated as a wall and verandah plant. In the warmer parts of China, and when cultivated in this country under glass, it is sub-evergreen, but is invariably deciduous in the open air. The leaves are trifoliate, the leaflets bluntly ovate, small individually, but very numerous, and of a deep glossy green colour.

The flowers are large, bright yellow, and borne in great profusion along the sides of the young shoots. In mild seasons this fine shrub begins to develop its showy blossoms so early as December, occasionally much earlier; but the usual time is from the beginning till the end of January, the flowers continuing to expand for nearly a month. When in full bloom it is a beautiful object—the grassy green but leafless branches contrasting pleasingly with the Primrose-like blossoms, which are all the more appreciated from their appearing at that dead season when, out-of-doors at least, there is an almost entire absence of floral beauty. Since its introduction it has been extensively employed for covering walls, for which its free-growing rambling habit renders it peculiarly adapted, and being very hardy, it is equally valuable for planting on bowers or trellis screens. It should always have a warm sunny aspect, and prefers a rich deep soil. Of this species a variegated form is in cultivation, and known as *aurum variegata*. It is a pretty plant, and well worth cultivating for its leaves, which are prominently edged with bright yellow.

The Common *Jasmine* (*J. officinale*).—This grand old-fashioned plant is said to be indigenous to various countries in the south of Asia, and, according to some authorities, has been in cultivation in Britain for nearly 300 years. It is a robust growing sub-evergreen, with numerous slender stems, attaining lengths of from 20 to 30 feet, and frequently making growths of above 6 feet in a single season. The leaves are bright green, pinnate, with from five to nine ovate sharp-pointed leaflets—the terminal one much longer than the others. The flowers are produced in corymbs at the points of the young shoots from June to August; they are pure waxy white, and deliciously scented. Of this well-known and highly valued shrub it is scarcely necessary to say, apart altogether from its beautiful fragrant flowers, which render its presence always acceptable, that it is one of the handsomest and most useful in cultivation for clothing lofty walls, bowers, or verandahs, as it is perfectly hardy, and also grows with the greatest luxuriance in almost every situation and in every variety of garden soil. The flowers are, however, most freely produced when it is planted in a dry soil, and in an aspect fully open to the sun. Among varieties, of which there are several to be met with in collections, the most desirable is *aurum variegata*, the leaves of which are blotched or margined with bright yellow. It is not nearly so robust in its growth as the parent, and is somewhat susceptible to injury from frost. It is found to succeed, however, in the milder districts on walls, but is more frequently cultivated as a greenhouse climber, and as such it is very effective.

The Curled-flowered *Jasmine* (*J. revolutum*).—Found wild over a wide area in northern Hindostan and Nepal, chiefly in high mountain valleys, forming a rambling sub-evergreen shrub of from 10 to 20 feet in height. It has been cultivated in British gardens since 1812. The leaves are pinnate, with from five to seven leaflets of a dark glossy green colour. The flowers are bright yellow, very fragrant, and borne in corymbs from the points of the young branches. They begin to expand about the end of May, and continue in more or less perfection till October. It is a remarkably free-growing wall shrub, quite hardy in most localities, and so attractive in foliage and flowers as to render it very desirable for the ornamentation of garden walls, or other buildings where a really handsome shrub is required. In severe winters it frequently casts its leaves entirely, but in most cases a considerable portion of them remain on till the return of the growing season. It succeeds well in any ordinary garden soil if moderately rich, and to secure a plentiful display of bloom, it should always be planted in a warm sunny aspect.

Dr. Wallich's *Jasmine* (*J. Wallichianum*).—This is sometimes called *pubigerum*, but it is now best known under this name, which was applied to it in compliance to Dr. Wallich. Like the preceding, it is found wild in various parts of northern India, whence it was first introduced in 1827. It grows to similar heights as *J. revolutum*, and otherwise so closely resembles that sort as to justify the suggestion of some writers that it is probably only a variety, and not entitled to be ranked as a distinct species. It is, however, very distinct—the habit of growth being more dense, the shoots more slender, and both flowers and leaves smaller, than those of that species. The leaves are pinnate, with from seven to nine leaflets of a dark-green colour. The flowers are bright yellow, and are generally produced very profusely from June till October. Like all the other *Jasmines*, it is a grand wall plant, quite hardy, and of easy culture in any kind of rich soil, and flowers best in a sunny aspect.—“The Gardener.”

***Cedrela sinensis*.**—Mr. Ellacombe asks whether *Cedrela sinensis* and some other north Chinese plants are in cultivation. According to the *Revue Horticole*, *Cedrela sinensis* is in cultivation in France. It is quite hardy in Paris, where there is a tree, in the *Jardin des Plantes*, 25 feet high. M. Carrière at first supposed it to be a new species of *Ailantus*, and described it under the name of *A. flavescens*. Subsequently he identified it with *Jussieu's Cedrela sinensis*.—W. B. H.

THE KITCHEN GARDEN.

LORD CATHCART'S POTATO COMPETITION.

The following is Mr. Carruthers' report on the results of the competition of 1874 for the society's prizes for Potatoes that should be free from disease for three years in succession:—"The ignorance prevailing in regard to the true nature of the plague which for thirty years has been so destructive to our Potato crop was singularly manifested to the judges who undertook the task of adjudicating the prize offered by Lord Cathcart in the autumn of 1872, for the best essay on "The Potato Disease and its Prevention." The ninety-four competition essays were written, with very few exceptions, by practical men—growers of Potatoes—but only a small proportion showed any acquaintance on the part of the authors with the agent which destroyed the Potato. Unable to advise the bestowal of the prize on any of the competitors, the judges, considering the importance of the subject, the renewed attention given to it, and the defects in our knowledge of the parasite causing the disease, resolved to recommend to the Royal Agricultural Society to take the matter up as a subject of investigation, in the hope that some genuine addition to knowledge might be made, and some practical hints for the future guidance of cultivators might be secured. The society, approving of this recommendation, resolved to promote investigations as to the more strictly scientific aspect of the subject. They entered into correspondence with Professor De Bary, whose important additions to the knowledge and history of the Potato fungus, and whose elaborate memoir of the group to which it belongs, pointed him out as the fittest botanist to undertake this part of the work. Professor De Bary has cordially entered into the society's plans; and has now for some time been carrying on experiments and observations with the view of determining those points in the history of the parasitic fungus which are yet unknown. The society further resolved to look at the subject in its practical bearings, and endeavour to gain facts from the past experience of Potato-growers, and from experiments to be instituted, which might concur with the more purely scientific investigations to a definite apprehension of the Potato disease in all its bearings. A series of questions were accordingly addressed to extensive Potato growers throughout the United Kingdom; the answers have been digested by Mr. Jenkins, and published in his report on the subject in the last volume of the Society's Journal. It is there pointed out that in two cases where Potato crops followed Turnips they had been free from disease; and having suggested that the fungus might pass through different stages of its life on different plants, Mr. Jenkins proposed that observations should be made to discover if any connection existed between the previous cereal or Clover crop and the presence or prevalence of the disease. Still further, it having been asserted by many that certain varieties of Potato were free from disease, and this opinion being believed by many cultivators as well as dealers, the society resolved to offer prizes for early and late Potatoes, possessing good cropping, cooking, and keeping qualities, which would continue free from disease for three years, during which time they would be cultivated in different localities, under the direction of the society. It was required that the competitors should forward a ton of each sort intending to compete in twenty bags containing each 1 cwt. To prevent any but those who had some confidence in their Potato entering as competitors, it was required that the owner of any sort which should be attacked by disease during the experiment, should undertake to pay a considerable sum towards the expense incurred in growing his unsuccessful Potato, although this condition was not eventually put in force.

Before the end of February, 1874, six varieties of Potatoes had been delivered to the society's agent to compete for the prizes, two being early and four late varieties. They were as follows:

Early Potato, No. 1.—Wheeler's Gloucestershire Kidney.—This was raised from seed in the neighbourhood of Bristol about twelve years ago, but it is not known by whom. Its owners consider the special features which distinguish it to be freedom from disease, earliness, and good size and colour; it has also a fine flavour, and is a good keeper and an excellent cropper. The competitors are J. C. Wheeler & Son, Gloucester.

Early Potato, No. 2.—Carter's Ash-top Flukes.—This was raised from seed by the competitors about five years ago, and is characterised by them as being early, very productive, a good boiling kind, and remarkably free from disease. The competitors are James Carter, Dunnett, & Beale, London.

Late Potato, No. 3.—Carter's Improved Red-skin Flour-ball.—This was selected by the competitors in 1871 from a variety called Champion of England, raised by Mr. Barkshire, of Reading, and is characterised by its owners as being prolific, white-fleshed, and remarkably free from disease. The competitors are James Carter, Dunnett, & Beale, London.

Late Potato, No. 4.—General Grant.—This was raised by Mr. D. Cunningham, of Athy, Kildare, from a few tubers which he received from America. Its special features, according to the competitors, are that the shaws keep green when other varieties are blackened, the tubers are large and well formed, and it is the only late variety which resists disease. The competitors are Thomas M'Kenzie & Sons, Dublin.

Late Potato, No. 5.—Gleason's Late, or Hundredfold Fluke.—The origin of this Potato is not known, further than that it was imported by a Potato salesman in 1870. The competitors characterise it as having the haulm robust, branching, about 2½ feet in length; stem, of a reddish tinge; leaflets, flat-pointed, green, with coloured veins; flowers, purple, generally sterile; tubers, large, generally broad, flat, sometimes irregular in form, as if two or three were joined together; eyes, few and full; skin, smooth, very pale, with large bands or patches of rosy-purple; flesh, white, and rather hard; it is, though late, a good average cropper. The competitors are James Carter, Dunnett, & Beale, London.

Late Potato, No. 6.—Peach Blossom.—This Potato was raised by the competitor from tubers received in 1869 from New York. It is characterised as a good prolific Potato, and without disease during the four years it has been grown in this country. It is not ripe for use until November or December. The competitor is Baron Middleton, Boisdale House, York.

The committee fixed on twenty localities in which to grow these experimental Potatoes, selecting them in districts where Potatoes are extensively cultivated, and securing as far as possible as great a variety of climate, and method of cultivation as could be obtained within the United Kingdom. The hearty co-operation of the following gentlemen practically interested in the culture of the Potato in these various districts was obtained. They undertook to grow a cwt. of each of the six kinds of competing Potatoes.

1. Kent.—Mr. Robert Lake, Oakley, Higham, Rochester.
2. Essex.—Mr. Richard Spencer, Brooklands, Birchinger, Bishop's Stortford.
3. Bedfordshire.—Mr. G. J. Cocking, College Farm, Bedford.
4. Staffordshire.—Mr. John Brown Sandhills, Walsall.
5. Lincolnshire.—Mr. J. Algernon Clarke, Long Sutton.
6. Yorkshire.—Capt. R. S. Best, Moorfields, Goole.
7. Northumberland.—Mr. John Angus, Whitefield, Morpeth.
8. East Lothian.—Mr. Samuel D. Shireff, Saltcoats, Drem.
9. Perth.—Colonel Ogilvy, Mill Hill Farm, Inchture.
10. Elgin.—Mr. Thomas Yool, Coullard Bank, Elgin.
11. Essex.—Mr. John Day, Essex.
12. South Wales.—Mr. W. S. Powell, Eglwysunydd, Taibach.
13. North Wales.—Mr. John Roberts, Well House Farm, Saltney, Chester.
14. Lancashire.—Mr. Richard Simpson, Ott Revellife, Garstang.
15. Cumberland.—Mr. Thomas Gibbons, Burnfoot-on-Esk, Longtown.
16. Devon.—Mr. Robert Wallace, Brashed, Ayr.
17. Munster.—Mr. A. J. Campbell, Fermoy.
18. Connaught.—Mr. John Nesbitt, Garbally, Ballinasloe.
19. Limerick.—Mr. J. A. Farrell, Moyally, Co. South.
20. Ulster.—Miss Rose, Mullaghmore, Monaghan.

These various growers were supplied with instructions as to how the experiment should be conducted. They were requested to plant the competing Potatoes in adjacent plots in the same field with their own Potato crop, keeping each sort distinct, and submitting all to the same treatment as their ordinary crop. Each cultivator has, in answer to a series of questions, supplied information as to whether his district is open or wooded, and has much hedge-row or other timber on the land; as to the soil, sub-soil, drainage, and slope of the particular field in which the Potatoes were growing; as to the previous cropping of the field; the kind of Potato forming his general crop; the processes followed in preparing the land for the Potatoes, including a statement of the manure employed, the distance at which the seed-tubers were planted, and the quantity planted in relation to the space occupied. These different items of information have been brought together in a table, so that the different methods may be very easily compared and contrasted. Information has also been obtained as to the after-cultivation of the crop, and the monthly appearance of the experimental plots and the general crop. A book was prepared and forwarded to each grower for recording these matters. This book also contained a calendar for a daily record of the weather. With a single exception these books have been kept with great care, and from them has been derived the greater proportion of the facts contained in this report. The committee requested me to inspect all the plots while the Potatoes were growing. Between the 27th July and the 4th September I accordingly visited all the localities; beginning in the south of England, and travelling northwards until I reached Lancashire, then crossing to Ireland, and after inspecting the four plots there, returning again to the north of England, and prosecuting my journey northwards till I finished at Elgin. The committee further secured the assistance of five gentlemen to be present on behalf of the society at raising the crops, to superintend the operations, and determine whether the disease had attacked any of the tubers, and if it had, to determine the extent of the injury. Professor Baldwin, of Glasnevin, undertook this work

for Ireland; Mr. Thomas Mylno, of Nidderly Mains, Edinburgh, for Scotland; Mr. W. H. Waksfield, of Kendal, Westmoreland, for the north-west of England; Mr. Jabez Turner, for the east and north-east; and myself for the southern districts. Instructions were given to these judges to have all the Potatoes attacked with the disease separated from the others, and to weigh the produce in the field. They were to record in a schedule, with which they were provided, the weight of healthy Potatoes in each plot, of diseased ones, the size of each plot, and the rate of produce per acre. They were asked to supply also the same information about the general crop in each farm, and to record any observation which might be of interest in connection with their inspection. These reports were all duly made. The whole of the Potatoes were packed, the healthy and diseased tubers of each plot being kept separate and carefully labelled. They were then despatched to London, and received at the Agricultural Hall, where, by the courtesy of the directors, they were for some time accommodated. This report is based on the books kept by the growers on the notes made by myself in the course of my inspection of the growing crops, and on the reports of the judges who were present at the raising of the crops. The six tons of competing Potatoes (each ton in twenty equal sacks containing 1 cwt. each) were received in London in the end of February, 1874, and were despatched to the various growers in the first week of March. When the bags were opened at their destination the growers found in some that a few of the tubers were rotten. Mr. Campbell, who carefully examined the tubers and separated the rotten from the sound ones, believed the injury was due rather to frost and bruises sustained in transit than to disease. His opinion is confirmed by his interesting observations on the growth of the Potatoes. He counted all the sets which he planted, and afterwards the number of plants which grew in the drills. The results are shown in the following table:

TABLE SHOWING THE NUMBER OF SETS PLANTED AND PLANTS THAT GREW IN THE EXPERIMENTAL PLOTS ON MR. CAMPBELL'S FARM AT FERMoy.

No.		Sets Planted.	Plants Grew.	Percentage of Growing Plants.
1	Early	1,530	303	19.8
2	" " " " " "	1,069	173	8.7
3	Late	1,410	457	32.4
4	" " " " " "	1,107	474	42.8
5	" " " " " "	1,065	517	48.5
6	" " " " " "	1,685	1,115	66.9

These figures clearly show that a further injury had befallen the Potatoes than the careful inspection to which Mr. Campbell subjected them was able to detect. I am satisfied that no tuber attacked by disease or suffering from ordinary rot escaped him. But some hidden injury was present, such as might be the result of the exposure of the tubers to a severe frost. Yet that this injury, whatever it was, was not entirely produced during their transit from the competitors' premises to the growers is manifest from the fact that in all the experimental plots the No. 2 early Potato showed numerous blanks, and that the failures of the seed Potatoes of the other varieties were everywhere approximately in the same order as at Kent. The short journeys to the neighbourhood of London, as to Kent, Essex, and Bedford, of seed that had been stored in London, would of course save it from the injuries and dangers incident to a lengthened journey, like that to Ireland, with its repeated transhipments. We have fortunately a series of similarly extensive and careful observations by Mr. Spencer, of Essex. He examined the seed, separating each bag into three lots — 1, the healthy tubers of the particular variety; 2, the healthy tubers of sports, accidentally introduced among the true seed; and 3, diseased tubers. In all of the competing varieties, except in No. 6, he discovered tubers, more or fewer which were, he believed, affected by disease. Mr. Simpson, Lancashire, detected also apparently diseased tubers, in the seed of No. 2, early, and No. 4 late. The results of Mr. Spencer's observations as regards the germination of the seed-tubers are thus tabulated:

TABLE SHOWING THE NUMBER OF SETS PLANTED AND OF PLANTS THAT GREW IN THE EXPERIMENTAL PLOTS ON MR. SPENCER'S FARM, ESSEX.

No.		Good Sets Planted.			Plants Grew.	Percentage of Growing Plants.
		True.	Sports.	Total.		
1	Early	1,031	—	1,031	1,020	99.9
2	" " " " " "	1,107	—	1,107	713	64.4
3	Late	563	21	574	539	92.1
4	" " " " " "	512	18	530	457	86.2
5	" " " " " "	655	11	666	632	94.9
6	" " " " " "	657	1	658	646	98.1

The tubers believed to be diseased were planted at the end of each lot. When the injury to the tuber had not been so great as to kill the eye or bud and destroy the starch-food needed for the germination of the bud, these tubers grew, and were, when I examined them on the 28th July, all perfectly free from disease. A large proportion, however, did not grow, as shown by the following table:

TABLE SHOWING THE NUMBER OF APPARENTLY DISEASED SETS PLANTED AND OF PLANTS THAT GREW FROM THEM, IN THE EXPERIMENTAL PLOTS ON MR. SPENCER'S FARM, ESSEX.

No.		Diseased Tubers Planted.	Plants Grew.	No.		Diseased Tubers Planted.	Plants Grew.
1	Early	6	0	4	Late	6	3
2	" " " " " "	75	3	5	" " " " " "	2	0
3	Late	14	5	6	" " " " " "	0	0

I learned from Mr. Spencer that he had in the previous year's experiment with diseased seed-tubers with the view of determining the relation of their products to the disease; and he had observed that the plants grown from them were not more liable to be attacked by the disease, or to suffer from it, than those grown from healthy tubers. The aspect of the eleven plants, when I visited the experimental plots in Essex in the end of July, corroborated Mr. Spencer's conclusions. This is of considerable value in relation to the yet unsolved question as to how the fungus causing the disease maintains its existence from the autumn to the following July or August, when under favourable circumstances it suddenly appears and spreads with wonderful rapidity. It rather tells against the opinion that the life of the fungus is maintained by planting diseased tubers; for, instead of the disease appearing first in the plants produced from them, these plants suffer only along with, and in the same proportion as, their neighbours produced from healthy seed. On the other hand, it must be remembered that if the mycelium of the parasitic fungus developed in a single plant grown from a diseased tuber, and this mycelium fructifies, the enormous mass of seed which is rapidly produced and re-produced under suitable conditions, would fully explain the spread of the disease. We look forward with much hope to the observations and experiments that Professor De Bary is now prosecuting for light on this obscure part of the history of the Potato fungus. In the stations in the south and east of England, and the south of Ireland, all the seed-tubers were in the ground before the close of the month of March; in the north and west of England, in Scotland, and in the north of Ireland, they were all planted before the middle of April. The information obtained from the growers, or observed during my visit to the different localities where the crops were growing, as to the nature of the soil, previous cropping, the preparation of the land, the manure, and the time and manner of planting the seed, will be best appreciated in a tabular form, where the eye can readily compare and contrast the various data given. The season of 1874 was dry up till the end of July and the beginning of August, when frequent and sometimes heavy rains occurred. In the progress of my inspection of the crops I met with no disease till I passed over to Ireland. Thereafter, throughout Ireland and Scotland, and the north of England I found the experimental crops diseased, except in Northumberland and East Lothian. At Elgin some of Mr. Yool's general crop was effected by disease, but I was unable to detect any among the experimental plots, though it was found to be present in three kinds when the Potatoes were raised, but then only to a very small extent. The disease appeared suddenly in Ireland, and spread with its wonted rapidity. In a few days after its appearance the fields in the south and west of Ireland were black. I visited Fermoy (Munster) on August 15th. The crops had been progressing satisfactorily till the beginning of the month. Until July 28th there had been no rain on the field in which the Potatoes were growing since they were planted, but on that day there was a heavy shower, and showers occurred during several succeeding days. On August 4th the leaves of all the experimental crops, as well as of the regular crop, showed here and there the presence of disease; and on the 15th I found that it had reached the tubers in some cases. When I reached Ballinacloe (Connacht), on the 17th, the extent of the injury from disease was greater. The field in which the Potatoes were growing had been recently reclaimed from bog, and was almost a black peat. The whole of the plants were remarkably vigorous, but the foliage was extensively diseased, and the tubers were also affected. The early suffered more than the late varieties; but when the crop was raised it was found that there was 21 per cent. of the early, and 27 per cent. of the late, diseased. At Monvalty (Leinster) the Potatoes were grown in lazy beds in a field which had been a neglected pasture for a great many years, and which was in very bad condition. On August 18th all the sorts were attacked by disease, the early again showing a greater injury than the late varieties. The disease first appeared in the Potatoes growing under some large trees which

bordered the field; at the time of my visit the foliage in these patches was quite blackened. When the crop was raised more than a fifth of the late varieties were diseased, and a smaller proportion of the early ones. The Potatoes were in a very flourishing condition at Mullaghmore (Ulster), when I visited them on the 19th August, but the disease had made its appearance some days before, and already it was visible on the foliage of all the plots as well as of the general crop. In the prosecution of my inspection I found the disease present in the plots at Longtown and Perth, and more extensively at Ayr. At Elgin some of the general crop was injured by the disease, but as I have already stated I did not detect any trace of the disease at the stations in Northumberland and East Lothian. The result of this visit to the various localities left no uncertainty as to the competition for the society's prizes, but it was determined to carry out the programme fixed upon. The condition of the crops as affected by the disease at the time they were raised is exhibited in the following table:

Earlies.	Per-centage.	Lates.	Per-centage.	Both Varieties.	Per-centage.
Ayr	60.5	Connaught ...	27.1	Connaught ...	25.3
Cumberland ...	24.2	Exeter ...	24.8	Ayr	23.6
South Wales ...	23.4	South Wales ...	22.4	South Wales ...	22.4
Connaught ...	21.7	Leinster ...	21.4	Exeter ...	20.9
Munster ...	18.6	Munster ...	10.3	Leinster ...	18.9
Ulster ...	18.0	Ayr	3.2	Munster ...	13.0
Perth ...	15.2	Lancashire ...	4.4	Cumberland ...	10.9
Leinster ...	14.0	Cumberland ...	4.3	Ulster ...	7.4
North Wales ...	13.3	Perth ...	3.4	Perth ...	7.3
Exeter ...	13.0	Ulster ...	2.2	Lancashire ...	6.5
Lancashire ...	10.7	North Wales ...	0.0	North Wales ...	4.4

The only locality that entirely escaped the disease was Long Setton, Lincolnshire. In the other localities not included in the above table, traces of the disease were detected, varying somewhat in extent. Stafford had the largest proportion, and the others followed in this order—Kent, Northumberland, Essex, East Lothian, Yorkshire, and, lastly, Elgin. In examining the information already given in the tables and body of this report with the view of discovering, if it be possible, an explanation of the greater prevalence of the disease in some districts than in others, it is important to notice the common starting-point in these experiments, and where the different conditions and agencies come into operation. The seed-tubers were in every case of the same stocks, and they were carefully selected, and believed by their respective owners to be characterised by a remarkable freedom, if not entire immunity, from disease. Each of the six bags received by every grower contained the same weight of the same kind of seed. The differences of condition and treatment began when the seed came into the possession of the growers. When the crops were raised the greatest differences as to the disease were found to exist in the various localities. At Lincoln the whole of the experimental crops were entirely free from disease, and comparatively little was seen in any of the plots on the eastern side of Great Britain, while at Ayr three-fourths of one of the early varieties were diseased, and at Connaught a half of one of the late varieties, and all along the western districts of the kingdom the crops were extensively destroyed. It seems obvious from these well-marked differences that the kind of the seed-tubers, which were the same in all the localities, cannot be the efficient cause of the disease. We may consequently set aside all the notions, still to a considerable extent prevailing, that the disease itself is due to anything peculiar to the variety, as, for instance, its supposed exhaustion from long cultivation of the tubers. It will be observed that in the same field and with the same treatment the second suffered much more than the first early Potato, while among the late varieties the fourth suffered the least, the sixth the most, and the third and the fifth were almost equally affected. Still further this relation of liability to disease persisted, with an approach to uniformity, in the various localities, so that, as a rule, the fourth was the least affected by the disease, and the sixth the most. The tendency of these results is to support the opinion that a Potato may be found which will successfully resist the disease. In the crops at Exeter, South Wales, Connaught, and Leinster, the fourth late Potato suffered to the extent of only 11.6 per cent., while the sixth in the same four localities suffered no less than 43.8 per cent. The external conditions of each of the kinds being invariably the same in each locality, it appears that the power to resist the attack of the fungus is due to some inherent property in the plant which is common to all the plants of the variety. Whatever this property is, there seems no reason to doubt that a difference which has shown itself so obviously in these localities may be found in some varieties sufficiently pronounced to free them altogether from the attack of the disease. I have made a microscopical examination of the leaf epidermis of the six kinds of Potato with the view of ascertaining whether any character could be detected which might explain the freer access of the spores to one

variety than to others. The upper surface of the leaf is sparsely covered with short curved hairs, which rise irregularly from the epidermal cells. These hairs are almost entirely confined on the under surface to the veins and their various and minute ramifications. The epidermis of the spaces between the veins gives off some scattered granular hairs, composed of a small round transparent ball supported on a short jointed stalk. In none of the varieties are these hairs sufficiently numerous to prevent the spores lodging on the surface of the epidermis. The leaves of the two early Potatoes are most densely covered with both kinds of hairs. I found no appreciable difference in the four late varieties. In looking, then, at the conditions naturally applied under which the crops were grown, we may hope to find in them some help towards understanding the remarkable differences that are exhibited in the tables. We may at once dismiss the soils from our consideration, seeing that the disease was severe as well on the peat of Connaught as on the loam of Ayr and South Wales, and the stiff clay of Exeter, while similar soils in other localities were free from the malady. The information supplied by growers of Potatoes led Mr. Jenkins, in his recent report, to suggest the probability of the fungus which produces the disease being parasitic during part of its life on some other cultivated crop. As parasitic fungi, which, as far as the knowledge of them has been ascertained, might be related to the Peronospora of the Potato, had been found on Wheat and Clover, and as the Potatoes that escaped disease, in the returns on which this report was based, followed green crops, Mr. Jenkins recommended that observations should be instituted with the view of determining whether Potatoes following Wheat and especially Clover, were more liable to disease. Professor Farlow has as we have seen, recommended the prosecution of similar inquiries in America. Last year's experimental crops do not give any support to the suggestion of Mr. Jenkins. In two localities Staffordshire and Lancashire, the Potatoes followed Clover, and though in both places disease was found to have attacked all the kinds of Potatoes, it was only to a small extent. In the majority of cases, as was to be expected, the Potatoes followed crops of Cereals; in the localities where the disease chiefly prevailed there were Oats, but at Exeter the preceding crop was Wheat. In one place, South Wales, they followed Turnips, and here the Potatoes suffered considerably from disease. As far as then, as these experimental plots throw any light on the subject, it appears—1, that the oospores of the fungus do not exist in the tuber, as has already been fairly demonstrated by the many careful investigators who have failed to discover them in the tubers they have examined for this purpose; and, 2, that the oospores are not produced in the plants of previous crops. These side lights may lead to the discovery of the wrong link or links in the history of the Fungus, but we must look to the labours of the cryptogamic botanist for satisfactory information, and it is matter of congratulation that the Royal Agricultural Society have been so fortunate as to secure the co-operation of Professor De Bary in this work. The presence of the disease is ascribed by many to the use of certain manures. Artificial manures, guano, and farmyard-manure are respectively condemned by different growers, each without any sufficient reason; while particular manures are put forward as specifics against the disease, as well as advantageous to the crop. If the hitherto undetected oospores of the fungi were introduced to the Potato field with the manures, it is obvious that artificial manures, from the methods of their production, must be entirely free from these bodies. In three localities artificial manures only were applied to the crops, but the results do not hold out any hope that in this direction security may be obtained. At Exeter 2 cwt. of nitrate of soda, and 3 cwt. of dissolved bones were applied per acre, but a quarter of the late varieties were diseased. The early Potatoes escaped with a smaller proportion, but this was due to the fact that they had ripened, and the foliage of most of them had completely disappeared before the disease showed itself in the last week of August. It is certain, moreover, that the full extent of the disease was not detected at Exeter when the crops were raised, as the day was showery, and the tenacious clay of the field in which they grew so adhered to the tubers that it was impossible, without washing every Potato, to separate completely the diseased from the sound tubers. At Kent the only manure employed was half a ton to the acre of Odam's Potato manure, and though the injury here was slight, all the varieties as well as the general crop suffered from disease. At Bedfordshire 70 bushels of soot per acre were applied, and the crops were almost free from disease. In the seventeen other localities the chief manure employed was from farmyards. This manure might be the medium of introducing the disease as the oospores of fungi are remarkably indestructible and might resist the destructive action of the dunghill, and even pass, without losing their vital powers, through the alimentary canal of animals. There is, however, no indication in last year's experiments that the appearance of the fungus had any connection with farmyard-manure.

Lincoln, with 10 tons per acre, was entirely free from disease, and Yorkshire with 15 tons, and East Lothian with 25 tons, were but slightly affected, while similar quantities were employed in localities which suffered heavily. The result of Dr. Voelcker's experiments at Carlisle, showing that the kind of manure had no appreciable influence on the presence or extent of the disease, is confirmed by the experiments of last year. If we divide the twenty localities into two groups, the one containing the places where the disease occurred to any appreciable extent, and the other, those that were more or less completely free from it, it will be observed that they arrange themselves geographically, the first group being all (excepting Perth) on the west side of the United Kingdom, while the second are on the eastern side. This grouping does not, of course, depend on temperature, soil, or method of cultivation, as there is nothing in common among the members of each group in regard to these points. But the two have each a somewhat close agreement in regard to the rainfall, the amount on the western side being much greater than on the eastern, consequently this division gives us for the eastern stations the smallest amount of disease and the least rainfall, and for those on the western side the largest amount of disease and the heaviest rainfall. We have already seen that as long as the season continued dry the Potato crops were healthy, and that the disease immediately succeeded the heavy rains. There can be no doubt that the appearance and progress of the disease is intimately connected with the amount of moisture present in the atmosphere. Now that the fungus (*Peronospora infestans*, Mont.) has taken possession of

this adversary, we shall, yielding to circumstances, probably see the cultivation of the Potato travelling eastwards to the districts in our island where the rainfall is small, and the soil is naturally or artificially well-drained. Whenever the crops in the west can be secured before the July rains sets in, there is no risk. At Ayr Mr. Wallace grows early Potatoes extensively for the markets in the centre of England, and no crop could be more safe or profitable when thus managed. But the same field which yielded, early in the season, a heavy crop of perfectly healthy but immature tubers, produced in the autumn a crop of ripe Potatoes in which, in one of the varieties, three-fourths were diseased, while the whole six varieties were injured on the average to the extent of very nearly one quarter. The experiments of last year may supply information as to the best conditions under which the Potato can be grown. Does the exact information contained in the schedules of the growers and the judges throw any light on the great differences in the actual yield of each hundredweight of seed, or in the estimated yield per acre? The most obvious fact on the face of this table is that, with few exceptions, the varieties selected by each grower for his general crop yield a larger return than any of the competing Potatoes. The early kinds cannot, of course be fairly contrasted with late Potatoes in respect of weight of crop. But it may be noticed that in each locality the produce of the early varieties and of No. 5 late were greatly below the general crop; that in four localities (Stafford, York, South Wales, and North Wales) the produce of No. 3 was heavier; in two localities (Kent and North Wales) the produce of No.

TABLE SHOWING THE FIVE HEAVIEST CROPS OF THE LATE VARIETIES (3, 4, 5, AND 6), AND THE CONDITIONS UNDER WHICH THEY WERE GROWN.

	Yield of 4 cwt. of Seed.	Soil.	Drainage.	Manure.	Seed, Whole or Cut.	Size of Plot.	Space for each Set.	Estimated Weight per Acre.	Weight per Acre of Ordinary Crop.

our country, its spores abound in the air, and are ready to germinate whenever the proper conditions are present. As rain does not grow when stored in the barn, and deprived of moisture, so the spores of this Fungus cannot germinate without a supply of moisture. They may rest on the surface of the leaves of the Potato and remain perfectly harmless if the air contains no free moisture, for they can obtain none from the interior of the plant as long as they are external to it. In July or August, when the warm atmosphere drinks up to saturation the rain that has fallen, any slight reduction of the temperature, like that caused by the setting of the sun sets free a certain amount of water vapour; the spores are able to appropriate what they require of this vapour, and begin their active life by pushing out a small process or thread. Of all the spores which thus germinate only those that are in close relation to the host-plant are able to maintain their life. Stone and earth afford no nourishment to the young plant of the peronospora, nor even the leaves and stems of any of the plants on the surface of which it may germinate, unless these belong to the Potato. But when the small thread from the spore has pushed its way through a stomate or penetrated the skin, it obtains possession of a supply of food and moisture suited to all its needs, and speedily develops, destroying the plant in its progress, and throwing into the air myriads of new spores to spread the malady among the neighbours of its host. The successful cultivation of the Potato in relation to disease is then, judging from our previous knowledge and from the results of last year's experiments, really the problem of combating the free atmospheric moisture, a battle whose issue is not uncertain. And as we cannot cope with

4 was heavier; and in one locality (Lancashire) the produce of No. 6 was heavier than that of the ordinary crops in these various localities. Returns respecting the general crops were received from only twelve out of the twenty localities. At Ayr the general crop was taken out of the ground long before maturity; and at Perth the general crop had been raised, without taking any notice of the produce per acre, before it was known to Colonel Ogilvie that this information was wanted. The gross yield of the competing Potatoes and of the general crop in these twelve localities is shown in the following table:

TABLE SHOWING THE ESTIMATED PRODUCE OF THE EXPERIMENTAL POTATOES, AND THE ACTUAL PRODUCE OF THE GENERAL CROP PER ACRE IN ALL THE TWELVE LOCALITIES FROM WHICH INFORMATION HAS BEEN OBTAINED.

	Tons. cwts. lbs.
No. 1, Early	45 19 43
„ 2, Early	31 10 0
„ 3, Late	128 10 0
„ 4, Late	96 15 47
„ 5, Late	80 15 106
„ 6, Late	82 6 10
General Crop	126 10 16

If we except from this table the extraordinary crop of No. 3, which Mr. Brawn raised at Sandhills, Staffordshire, which raises the total yield of that variety to a higher figure than the general crop, it becomes obvious that the farmers who assisted the society are in possession of Potatoes which yield, in their various localities, heavier crops than, with similar treatment, they have been able to obtain

from any of the competing varieties. The great differences exhibited in the table in the actual produce of the 1 cwt of seed is very remarkable. In the first early, under the careful farming of Mr. Campbell, at Fermoy, there is a yield of only 88 lbs., or about three-quarters of the seed planted, while in Ulster Miss Rose obtained a crop weighing 10 cwt. 60 lbs. Again, at Morpeth a yield of 1 cwt. 51 lbs. was obtained from the seed of No. 4 late, while on the other side of the country, at Ayr, the same seed produced 1½ cwt. 18 lbs. It is obvious from these and similar facts exhibited in the table that all the varieties of Potatoes are not equally suitable to the different conditions of soil and cultivation met with in Britain. This is further confirmed by the fact already noticed that the competing Potatoes in almost every case yielded a smaller produce than the varieties cultivated for the general crop in each locality. In examining the conditions under which the best crops have been produced in the various localities, it is extremely difficult to discover any conditions that are common to several of them. There is, in these experiments, an amount of certain data which might be expected to supply materials for trustworthy deductions; but we discover, as is so often the case in agricultural experiments, many unaccountable anomalies. The agreements and differences should be most obvious when the localities producing the heaviest crops are contrasted with those producing the lightest. The five localities yielding the heaviest return of seed produced also the heaviest estimated crop per acre, with the exception of Bedford, where the size of the plot was unusually large. But though the plot was large, the average space for each set was not more than 2·8 square feet, so that the division of the seed-tubers to form a large number of sets, while it produced a considerable return in weight for the weight of seed, yielded the comparatively small return of 4½ tons per acre. The seed Potatoes were cut under Mr. Cocking's instructions into as many pieces as could be obtained, so that each piece should have two eyes. The weight of the crop at Bedford was considerably affected by the very dry summer, which stopped the growth of the tubers before they attained their full size. When the rain came the foliage of the early Potatoes was dead; but that of the late varieties was still green and active, and in all of these a new formation of tubers began, either by the addition of a new portion to the apex of the already formed tuber, or more frequently by the throwing out from its buds or eyes of several new tubers. Half the weight of the crop at Bedford was due to these latter-formed tubers. In several other localities in England the crops were similarly but not so extensively affected as at Bedford. The aerial portion of the early Potatoes at Bedford being, as has been said, completely dead, the rains causing many of the tubers to sprout. It appears, then, from the results of the experiment at Bedford, that a large number of small sets do not produce so heavy a crop per acre as the same weight of seed planted in large sets. This is strikingly confirmed in Mr. Brawn's crop at Stafford, where, from cutting few of the seed-tubers, the hundred-weight of seed occupied, on an average, only 5½ poles. The yield of 51½ cwt. for the 4 cwt. of seed is a large return; but 18 tons per acre, on an average of the four late varieties and 27 tons for one of these varieties (No. 3), are remarkably heavy yields. On the other hand, at Ayr, the same quantity of seed, planted nearly three times the space, and while a heavier yield, weight for weight, was secured, the estimated produce, per acre, fell to 8½ tons. It appears then from these and other instances, which an examination of the tables will show, that the Potato which starts with a large supply of food in the tuber, and secures by its help a good hold on the soil and a good mass of foliage in the air, produces the most remunerative crop. The multiplication of the seed in these experimental crops by cutting the tubers, means, of course, nearly the same as occupying a large plot, for, as the space allowed by the different growers for each set was tolerably uniform, and as the number of seed-tubers was practically the same throughout, the necessity for a large plot was due to an artificially increased number of sets. The tables in this view confirm the conclusion already stated, that a given weight of seed may be spread out as greatly to reduce the yield, per acre, of the crop, even though the sets are not widely separated, but placed at a moderate and uniform distance from each other. The average space allowed to each set is from 2½ to 3 square feet. This is somewhat more than the space which Mr. Maw determined to be the most profitable distance. His experiments showed that to give more than 2 square feet to each set gave no advantage in the shape of an increase of weight. It deserves the consideration of growers, in the face of his results, whether too large a space is not given to each set, and the produce, per acre, accordingly reduced. Thus, to take the most extreme case in these experiments, had only 2 square feet been given to each set in the Essex locality, the produce of No. 3 late might have been 16 instead of 7 tons. The varieties of soil supply no sufficient explanation of the difference in amount of produce, although

the richest soils exist in the localities which produced the heaviest crops. It is still more remarkable that heavy manuring has not produced a corresponding result in the weight of crop. The experiments of Dr. Voelcker and the experience of growers point to the dung of the farmyard as the best Potato manure. Nevertheless, we notice that 40 tons of this manure, with 5 cwt. of super-phosphate applied as a top-dressing, produced 5 tons per acre in Munster, while 25 tons, without any artificial manure, gave a crop of 18 tons per acre in Staffordshire. It is, however, certain that the most successful Potato growers use a large amount of manure.—“Journal of the Royal Agricultural Society.”

PEAT.

PROPERLY speaking, peat comes under the head of soils, but it is frequently used as a manure, and often enough employed as a substitute for leaf mould. In many parts of the country it is more plentiful and easier procured than the latter; and I have known it applied with excellent effect to heavy soils for Potato crops. It is one of the best ameliorators of strong soils generally that can be used, and if laid up first as a compost with lime and other refuse for a few months, it becomes a highly nourishing manure. Carrots thrive amazingly in it, and all kinds of vegetables root quickly amongst it. Many plants which naturally grow in loamy soils will thrive in peat alone. The Pine-apple is not unfrequently grown most successfully in pure peat and sand. Plenty of people who cannot get leaf mould can get peat, and they may use it instead of mould for all purposes. Nurserymen use it extensively for nearly all indoor plants, and in greater proportion than most gardeners do; yet where do we find such healthy stock speedily got up? For mixing with loams for potting, I prefer peat to leaf mould; not used in a lumpy state, however, but thoroughly broken up and rubbed through a sieve, fibre and all. Composts for potting or any other purpose should always be thoroughly mixed, and this can only be done by first reducing the different materials to as fine a condition as possible by chopping them with the spade, and putting them through a screen, or teasing them out any way most convenient. Lumpy composts never are, and never can be, mixed as they ought to be for the roots of plants to lay hold of. One important quality of peat is, that it not only encourages the multiplication of roots, but preserves them better than any other soil. For this reason it is sometimes used for winter Cucumbers along with loam, a healthy root action being of most importance in the winter culture of these. I have used nearly pure peat for many years for autumn-potted Pine suckers, and invariably the roots of the plants are both healthy and abundant in spring. Peat soils differ widely in different localities, and some people are very particular in the kind they use; but I have used it of all descriptions, from the top spit of the swampy bogs in Scotland to the Heath of the English commons and the thin peat sods of the Yorkshire moors, upon which not heath, but wiry upland Grasses only grow, and have found all excellent for my purposes, only using more or less sand according to the character of the peat. Of course I always selected the most fibry kind. Of the famous Kent peat, now become a regular article of trade with nurserymen, I never bought a load, nor do I believe it is a whit better than the peat, procurable at the door in many places. That this opinion is by no means a common one, however, is evident from the fact that the Kent peat is bought by gardeners at only a little less than half the price of bones in districts where peat of excellent quality can be procured for nothing on the estate. As a rule, peat is better mixed with other soils than by itself. Turfy peat retains water like a sponge, and, when used by itself for peat-loving subjects, if not mixed with a good proportion of sand and well drained, it is apt to get sour with a few over-waterings; while on the other hand plants firmly potted in it, if allowed to get thoroughly dry at the root, can only be again soaked by steeping. In potting Heaths and such things, the utmost care should be taken to see that the ball is moist before potting, as, if dry, no amount of waterings will soak the old ball. Peat should not be used for potting purposes until the fibre is partially rotted. It then chops up easily, or may be rubbed through a sieve without loss, and is then in the very best condition for using. I always procure the sods when in a moist state, and lay them up in a heap under shelter for a few months. This kills the Grass roots, and the soil never gets too dry, whereas peat got in after a period of dry weather is often parched, and, when used, is hard and knotty.

J. S.

Use of Tan for Blanching Celery.—Owing to the very wet autumn we have had, and the difficulty of getting the strong soil of the kitchen garden here friable and dry enough for earthing up the late Celery crops, I used old tan for that purpose. I now find, on

taking up this Celery for daily use, that it is well blanched, crisp, and good flavoured, the white varieties especially showing none of the rusty-coloured spots, caused by little black slugs eating the outside stalks underground. I once used fresh tan for blanching Celery; but, unless the tan is charred in the ground after the Celery is taken up, a crop of Fungi springs up. The old spent tan, when well mixed with the soil after the Celery is taken up, is free from this; for I have never seen Fungi appear in it, as when new tan was used. Old tan, besides keeping the slugs in check, is excellent for preserving the Celery from severe frosts, as it often gets injured when earthed in the usual way.—WILLIAM TILLEY.

Failure of Winter Spinach.—This appears to be general this season, and that quite independent of soil or situation. I sowed mine about the second week in August, after the second crop of Peas were cleared off. The ground was dug, well trodden and raked over, and drilled 15 inches apart. The seed came up as evenly as if it had been machine-drilled. The ground is well sheltered from north-east to west, but fully open to the south, with an incline of 16 inches in 10 feet, the drainage being naturally perfect. In confirmation of this I may mention that I sowed a stoke hole, 9 feet deep, at the bottom of the garden. When occasion requires we draw off the water from several hundred feet of 4-inch piping, and it soon soaks away, yet half of my Spinach has died away as described by your correspondents—a result, I believe, brought about by the mild wet autumn which we have had and the saturated state in which the surface soil has been kept. There has also been a want of sun and wind to dry the ground between the rains. For seventeen years past I have never had Spinach fail here.—JOHN GARLAND, Killerton, Exeter.

Packing Lettuce.—The delicate Cabbage Lettuces, sent throughout the winter to our markets from the market gardens of Paris, are sometimes objectionable from the fine earth of the roots spreading over the Lettuce leaves. This necessitates the Lettuce

being washed, which, to many, is objectionable. The Cos Lettuce, however, which comes in early spring in great quantities, is frequently packed with paper, as shown in the accompanying little cut, and in this way comes without being soiled by the root earth.

Wintering Beetroot.—In wintering a large crop of Beetroot from which to grow seed the following year, I invariably adopt a plan which some years ago I saw answer admirably, at Motistown Abbey, Romsay. There the whole of the kitchen roots are laid beneath a grove of Nut trees, where the ground is light and comparatively dry. After Christmas, when severe weather may be looked for, leaves are shaken over them, and these, combined with the shelter afforded by the overhanging branches, effectually protect them. My roots are placed in a similar soil under the shelter of a spreading Oak, and with them are also the roots of my stock of *Salvia patens*. I find that Beetroot wintered in this way possesses a richer flavour than when stored in sheds or cellars, but especially are the crowns more healthy and robust for seed production.—A. D.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Walcheren Broccoli v. Snow's and other Winter Varieties.—We are just now (Jan. 4th) cutting three and four dozen small, but deliciously flavoured Walcheren Broccoli heads a week, and although we are growing in quantity Snow's, Backhouse's, and Oxborn's, not one of these has yet been cut. They are lifted, laid outside, and slightly protected with Fern fronds.—R. G., Burghley.

Snowball Cauliflower.—This delicious little Cauliflower is now being cut from the open ground, having become fit for use since the disappearance of the snow. The heads are about 4 inches across, and as solid and white as could be desired, whilst the flavour, from the plants having been grown without strong manure, is all that can be desired. This Cauliflower, if sown in July, can be made to produce an abundance of heads all through the winter, if the plants are lifted before any severe weather sets in. The size is so small that the plants will heart well if potted in 2½-sized pots, and placed in any vacant cool house.—D.

Shallots in Suffolk.—These are grown in almost every garden in this county, both large and small, the soil—a light sandy loam—being particularly favourable to their growth. They are generally preferred to Onions for pickling, as well as for a variety of other purposes. As regards cultivation, their bulbs are merely pressed into the soil 1 foot apart, each way, and afterwards they are kept free from weeds. They are fit for lifting about the end of June or early in July, and should be stored in a dry airy shed until wanted for use.—J. GROOM.

NEW PLANTS, &c.

Rheum nobile.—This noble plant was discovered nearly thirty years ago by Dr. Hooker, growing on rocky precipices of the lofty mountains of the Sikkim Himalayas. Its long fusiform roots lengthen into a short thick rhizome, throwing up each year a single erect stem close to that of the preceding season, growing to the height of a man, and probably taller under cultivation. The stem is completely clothed with leaves and imbricated reflexed bracts, forming conical or spiral masses of yellow, red-margined foliage quite distinct from anything else in cultivation. Seeds of this novelty have now been introduced and advertised by Mr. Thompson, of Ipswich, and others. The first figure of this noble-foliaged plant, which will doubtless become invaluable for sub-tropical gardening, was published in Hooker's "Illustrations of Himalayan Plants," and it is well figured in "L'Illustration Horticole," t. cxx.

Draba Mawii.—A dwarf-tufted Spanish species found by Mr. G. Mawe, in 1870, near Pancorbo, in Old Castile, between Burgos and Miranda. It is a pretty little plant, bearing a profusion of reddish-brown buds, and white flowers about half-an-inch in diameter. "Botanical Magazine," t. 6,186.

Crocus Boryi.—A very pretty autumn-flowering Crocus, a native of Greece, and first brought into notice by Colonel Bory in 1832. The flowers are creamy-white, with a yellow eye, and it is a very desirable addition to the autumnal species. Mr. Elwes found the plant growing at Syra, along with *C. Crewei* in 1875. "Botanical Magazine," t. 6,187.

Wahlenbergia Kitaiibelli.—A purple-flowered Hungarian plant, introduced by Messrs. Backhouse & Son from the Alps of Croatia. The flowers are deep purple-blue behind, and elegantly bell-shaped in form, being borne in dense clusters at the apex of the procumbent pinkish stems. The leaves are linear, and of a bright green colour. "Botanical Magazine," t. 6,188.

Delphinium Casmirianum.—A very showy herbaceous plant, found on the Western Himalayas at altitudes varying from 12,000 to 15,000 feet. The flowers are of a bright bluish-purple colour, borne on the apex of the leafy stems, the leaves being palmate and inciso-dentate like those of the common Monkshood. "Botanical Magazine," t. 6,189.

Masdevallia Davisii.—A very showy yellow-flowered Orchid, found near Cuzco, in Peru, and sent to Messrs. Veitch, who flowered it in August of the present year. It is quite distinct from all the other species, being a clear golden-yellow colour; the flowers are also very freely borne solitary on long scapes among the bright green fleshy leaves. "Botanical Magazine," t. 6,190.

Tulipa Eichleri.—A very showy species, native of Georgia, bearing large and showy crimson flowers, each segment elegantly incurved and having a blackish-purple spot at the base inside, surrounded by a yellow rim. It has been introduced by Mr. Elwes, and first flowered in the spring of this year. "Botanical Magazine," t. 6,191.

Heteranthera limosa.—A pretty blue-flowered aquatic, seeds of which were sent from Santa Martha (New Granada) to the Royal Gardens by M. Endres, and these germinated and flowered in a few weeks. It is widely distributed in both North and South America, and is worth culturing wherever pretty little aquatics are admired. "Botanical Magazine," t. 6,192.

Oxalis arenaria.—A very pretty free-growing species from Chili, where it is widely distributed, being found in sandy pastures near Valparaiso, Santiago, and other localities. The flowers are dark rosy-purple, borne six and eight together on a slender scape, the leaves being bright green and ternate, as in most of the other species of this large genus. "Botanical Magazine," t. 6,193.

Dion edule.—This is a strong-growing Mexican Cycad, something like *Cycas revoluta* in habit; its deep green leaves forming a crown on a trunk 2 to 4 feet in height. It rarely fruits in this country; but in Mexico the seeds are eaten as food by the natives. "Botanical Magazine," t. 6,184.

Notice to "The Garden."—This London journal in quoting an item about that best of Squashes, the Butman, speaks of it as a Squash Gourd. No, Sir, our Squashes are not Gourds any more than our Blackberries are Brambles, or Sweet Potatoes Yams, (as you had it the other day), or Sequoias Wellingtonias, and if you don't stop calling things "out of their names," and cease speaking of the Squash as a Gourd, we shall feel obliged to call the attention of President Grant to the matter. Recollect that we are near the Centennial birthday—and there are some things we just won't stand. British Garden beware! The Great American Potato Beetle has its eye on you.—"American Agriculturist."

IVY AND THE POETS.

The death of Hans Christian Andersen gives an especial interest to the following account which he recently gave of an interview with the poet Lauroto:—That was a melancholy meeting between me and the great English poet, in his quiet, unpretending home in the Isle of Wight. Fifteen years before I had visited him in company with Charles Dickens. Then we were in the best of humour, Dickens' sparkling wit carrying away with it not only poor me, who have always had a weakness for humour, but even the grave Tennyson, who looks as if it cost him a labour to smile. At that time Tennyson was a fine-looking man, with black hair and beard, and his face was scarcely furrowed. I thought I had greatly changed in these fifteen years, but he had evidently grown old much faster. As we shook hands we looked in each other's eyes, and his filled with tears. Why, I don't know exactly. I suppose it was a tribute paid to the memory of Charles Dickens. Indeed the words he uttered were:—"And this time you come alone, Mr. Andersen. Do you remember the theatrical performance at Gads'hill?" Why should I not? The play was "London Assurance," and the leading part was given by Charles Dickens. That was in 1853, and among the audience were Charles Read, Delane, and others whose names have since become famous. "What a time we had!" exclaimed Tennyson. "Yes," I replied; "and do you remember getting me out of bed a four o'clock in the morning, so that we might go with you to the Isle of Wight?" Of course he did, and he made me walk with him through the garden, as he had done fifteen years before. There was the tablet to the memory of young Hallam. It looked somewhat dimmer than in 1853, but it had been surrounded in the most æsthetic manner with the finest growth of Ivy. "Ivy seems to be your favourite plant," I said to Tennyson.—"To tell the truth, it is," he replied. "Ivy needs no nursing. It knows neither cold nor heat. It is the plant of immortality." "But what about Laurel?" I rejoined. "Laurel wreaths," he said, playfully, "look well enough in pictures, but in reality they wither too soon." How many writers have I seen wreathed in Laurel, and how soon it became dry and withered.

Gardening in Mysore.—At Bangalore, which is the chief town in the province of Mysore, the climate is very favourable for gardening. In 1874, the annual mean of the dry bulb thermometer, taken from the maximum and minimum daily corrected readings at the Observatory of the Civil Hospital, which is 3,000 feet above sea level, was 72°, and, 100 being the maximum, the humidity was 70, ozone 44, and clear sky 48. The rainfall was excessive, being 56½ inches as against the average of 36 inches. With the exception of 14 cents, on one occasion there was no rain whatever for the first sixteen weeks. In the two following weeks 58 cents fell at intervals, but from the 4th of May, the day of the cyclone, rain fell every week up to the end of the forty-fifth week. From the forty-sixth to the fifty-second week inclusive only 1¼ inch fell. During the present year, up to the 3rd of December, only 22 inches have fallen, and the scarcity of water is much felt. During 1874 the Magnolia flowered twice in the government gardens; the Wigandia, which is arborescent, was in full flower in November. The beds of Devonians and Emma Roses flowered freely on four different occasions, the Spathodea and the Bignonias venusta thrice. The Bougainvillea spectabilis, which always comes out in such marvellous beauty in February, flowered again here and there, in a tentative manner, during the wet weather in August, an occurrence that had not been observed previously. The heat during the early part of the year was very great, but as the garden is commanded by a good supply of water, and, as irrigation was carefully kept up during the time of drought, all the foliage plants seemed to revel in the sun, and to display their colours to greater advantage than I ever remember to have previously noticed.—J. P.

The Scarlet Runner (Phaseolus multiflorus).—This well-known plant was brought into this country from South America in 1638, and was first cultivated in Lambeth, by Tradescant; but it was merely planted as an ornament to cover walls and to form arbours, without any idea of cooking the pods for the table. Its flowers were in favour for nosegays, but its legumes did not come into use as an edible vegetable until brought into notice by Miller, in the eighteenth century.

Senator, Professor, and Market Gardener.—Lamartine, in his "Memoirs," gives an exquisite picture of M. St. Hilaire, after his expulsion from the chair of Greek and Latin at the Sorbonne, for refusing to swear fealty to the Empire, working as a market gardener. He retired in 1852 with an aged aunt, to whom he stood in lieu of a son, to a cottage standing in a patch of ground near Meaux; which she lived he went on cultivating vegetables for the Paris greengrocers,

whose patronage he was very glad to secure. M. St. Hilaire is now seventy years of age, and a hale hearty man. He is a member of the Assembly of France, one of the newly-elected senators, and was secretary to M. Thiers when that statesman was President of the Republic, and during the most trying crisis in the history of France.

Brownæa at Lakelands, County Cork.—This is flowering most profusely this winter, the magnificent *B. macrophylla* having had no fewer than ten of its gorgeous Rhododendron-like heads of fiery orange-scarlet blooms scattered over all parts of the tree, from close to the earth at the base of the trunk to the tips of the young branches, all being in full beauty at the same time; these blooms only remain in perfection for a couple of days, and then fall to pieces. At this moment (January 2) there are two fine heads of bloom on *B. grandiceps*, which is much less brilliant and striking in colour than the last-named variety, the flowers being of a light rose colour, and one fine head just beginning to fade, coming from a young shoot at the base of the tree on *B. latifolia*, which comes next in beauty and brilliancy to the first-named variety. Many of these fine stove shrubs in this rich collection have grown too tall for the somewhat low house, where they are most of them either growing in large tubs or planted out in a deep sunk border, and they have accordingly to be tied down to prevent them from pushing through the roof. I am happy, however, to say that Mr. Crawford is having an addition made of several feet in height over the whole house, and when this is completed and glazed, the present roof will be removed, and the tied-down specimens will be able to be released from the ligatures that now confine them, and expand themselves to their full proportions in their newly enlarged quarters. The beautiful and fragrant *Luculia gratissima* is now covered with its deliciously scented trusses of rosy-blush coloured flowers, growing in a large tub in a cold greenhouse at Lakelands.—W. E. G.

NOTES AND QUESTIONS—VARIOUS.

Mushrooms in Sawdust.—One of your correspondents asks if the flavour of Mushrooms is impaired by being grown in sawdust. I have this season a large bed made of this material after it has been used as bedding for horses, and I find that the flavour of the Mushrooms is in no way affected. Our sawdust is, however, prepared from fresh sound wood.—R. GIBBERT, *Burghley*.

Roses out of Doors in Hampshire.—This morning (January 4th) gathered from the open ground excellent blooms of the following Roses, viz., *Gloire de Dijon*, *Alfred Colomb*, *Duke of Edinburgh*, *Souvenir de la Malmaison*, *La Reine*, *Marie Baumann*, and *Baronne Frévoet*.—W. W., *Heckfield*.

Good Globe Artichokes.—No vegetable is here more esteemed than Globe Artichokes, but they must be fat and plump and of large size. We are just now thinning the old stools, leaving three of the strongest shoots, and putting 3 inches of manure among them, which acts not only as a mulch but as a protection.—R. GIBBERT.

Laurustinus for Cut Bloom.—Following Mr. Simpson's recommendation I got half-a-dozen standard *Laurustinus*, and just now (Jan. 4th) they are one mass of bloom, their flowers mixing up well in bouquets at this dull season. I consider them in perfection before the blooms open; they are then pure white, and do not droop.—R. GIBBERT, *Burghley*.

Sea-shore Live Oak.—Could any of your readers inform me what the "Sea-shore live Oaks" of the United States are, or the name of the tree whence the timber is produced? I have recently read in the papers that for ship-building purposes it stands unrivalled, resisting the wear and tear of years, and being practically imperishable. It is said, however, that it is fast disappearing, and that the supply will soon be exhausted.—V.

Enonymuses as Window Plants.—Few plants are more thoroughly adapted for balcony or window decoration than these. The golden and silver variegated varieties are much more conspicuously variegated than their roots are, and are in pots than when planted out, gross growth causing them to revert to the original green state. Even in the dry and often dusty atmosphere of living rooms these plants will keep healthy for a longer period than most others.—J. GROOM.

Cutting and Seed Boxes.—The season for propagating and seed sowing being close at hand, it is advisable to see that a good stock of these useful articles is in readiness, for where large quantities of bedding plants are grown it is endless work to put them in singly. I find that boxes 2 feet 6 inches by 1 foot 6 inches are much more serviceable than such as are much larger, as one man can readily move them about, whereas larger ones are not only cumbersome to move, but soon break in removal by the weight of soil which they contain.—J. G.

The late Frost in Cornwall.—We have had, down here a much harder frost than you have had—one night 16°, which killed a fine plant of *Enonymus*, but *Cyclamen persicum* is unharmed—indeed, the plants are still in flower, as if there had been no frost! I had for years thought this *Cyclamen* as hardy as the rest, and am quite convinced of it now. Five of my *Camelias*, 6 feet high, large bushes that have never been under glass that I know of, are injured.—J. B. BOGART, *Lewarne Rectory, Fonda*.

Bedding Calceolarias out of doors in Winter.—In addition to our regular stock of these that are wintered in ordinary cold frames, we have for several years put in a few rows of cuttings close under a north wall, as a chance crop, and without any protection, but the hard leaves of the fruit trees that rolled against them, or the occurrence of severe frost, a few evergreen branches laid on them. They stand ordinary winters, and make excellent plants with a minimum amount of labour.—J. GROOM.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

PLANTING TREES IN SUMMER.

It may be useful to place on record some of my experiences in planting, which, in some cases, may be exceptional, but from which I, at least, have learned some important lessons. I may add, too, that my opportunities of observation have been by no means limited, inasmuch as I have for some years been engaged in transplanting quantities of all sorts of choice trees and shrubs, varying from the more expensive of specimen Hollies and Japanese Conifers, through the whole range of Japanese and commoner shrubs, both deciduous and evergreen kinds of all ages. There is little doubt that planting can be carried on with perfect success throughout the whole of the winter months, when plants are in a dormant state, and I was compelled often to be very indifferent about the time when such work was done, provided always that the weather was sufficiently mild and free from frosts and cold dry winds. I am however, far from being satisfied that winter, when the vitality of trees and shrubs may be considered to be at its lowest ebb, is the best season for transplanting them. Take, for instance, Hollies, Berberis Darwinii, Skimmias, Japanese Conifers, Wellingtonias, Euonymuses, Escallonias, and others, all of which will be found to move more safely very early in autumn or early in summer, when their vital energies are active, than in winter. In the case of other subjects, it is interesting to remark the success attending their transplantation at different seasons. Last season, I transplanted some hundreds of thousands of trees, consisting of various sorts of Conifers and deciduous trees, the work of moving which extended over a period of six months, from the 1st of November to the 1st of May. The whole were lifted from a home nursery, and were virtually planted at once. At midsummer, it was easy to tell which were planted at mid-winter, which in autumn, and which in spring. Those planted latest in spring contained the fewest deaths; those moved in mid-winter and in March, the greatest number. The planting in autumn was not early enough; October would have been better. Of course, these were all plants of small size, moved without any balls of soil whatever; on the contrary, they were simply lifted from the nursery ground, and pit-planted in trenched ground. It was clear that such evergreen Conifers as Scotch Firs, Spruce, and Austrian Pines, succeed best when planted at the period when vitality was becoming active; being lifted at home, they had no time to become dried, and, being planted at once, they took to the ground directly. The case was, however, different with those planted in mid-winter, when they were dormant and the soil cold. Winter is, however, the time when trees and shrubs as articles of commerce can be best dug up without soil adhering to them, and sent to a distance by railway with least risk of suffering from dryness or heating, as is often the case when packed closely in boxes or railway-trucks. They will also keep longer alive in a dormant state, and wait the planter's time better than at any other season. Planting, too, can be carried on more conveniently in winter than at any other time, as labour is then more plentiful; it is the time, also, for carrying out ground-work and trenching; and altogether, from a labour point of view, winter is the most convenient season for extensive planting. But, having to deal with living plants more or less affected by the rigours of winter—some hardy and tenacious of life under ordinary circumstances, others tender, and requiring studious care—the most convenient season is not often that which is best to secure the safety of the trees. I have for years moved large quantities of trees and shrubs during the mid-winter months, with scarcely one failure; but they were carefully handled, and in most instances were furnished with good balls of soil. I have too, moved considerable numbers at midsummer with equal, or still greater, success; and those moved then always made the best growth the following season. Trees planted in winter invariably grow but indifferently the following summer; they seem to require a lengthened period to recover from the shock

of removal; but, in the case of summer-moved plants, the check is only temporary at the time of removal, and they grow away the following spring as if nothing had happened. The warmer the weather, too, the more successful, generally, are the results of planting, provided the subjects operated on are exposed as little as possible to hot sunshine. Three years ago I transplanted a large quantity of evergreen and deciduous trees and shrubs during a very hot fortnight in April; of these the most important part consisted of choice Conifers, such as *Cupressus Lawsoniana*, *Wellingtonias*, *Pinus insignis*—very healthy trees—*Thuja*s, *Picea nobilis* and *Nordmanniana*, *Abies orientalis* and *Douglasii*. In addition to these were also *Laurels*, *Catalpas*, *Scarlet Chestnuts* 15 feet high, *Tulip trees*, and *Liquidambars*, all pushing into growth. Lookers-on shook their heads in doubt, and I began to fear that operations had been begun too late, but the ground was newly trenched and mellow, and the trees were lifted by one set of men while another planted them almost directly; after planting, some were watered, but not very liberally, and the majority not at all; yet the result was most satisfactory, except in the case of a few *Wellingtonias*, which died back. I attributed my success to the hot weather which prevailed at the time. I warmed the soil and kept the sap of the plants moving; had there been cold easterly wind, with even cloudy weather, success might not have been so complete. Another exceptional instance of success in planting—this time when growth was at its height—may be noticed. Last summer, in the middle of July, I was obliged to transplant a quantity of evergreens and deciduous trees and shrubs to make way for some improvements in progress. We looked upon the work as a sort of forced experiment, most of the subjects being large, and the variety comprehensive, including Conifers, *Laurels*, *Rhododendrons*, *Lilacs*, *Forsythias*, *Weigelas*, *Leycesterias*, &c. Some could be lifted with balls, some not; none were allowed to be out of the soil many minutes; for, as soon as a plant was lifted, a pit was ready for its reception. It so happened that none had any artificial watering, the soil being light and moist from recent rain, and the work was conducted under a hot sun and clear weather; but thunder-showers fell after the planting was completed. In some instances the young growths hung down their heads immediately after transplantation, but invariably in the morning they were found to be erect, and the more healthy and succulent the plants, the better they seemed to stand removal. Of course, the whole were in active growth, and, in the case of the common *Laurels*, some of them very large bushes, although they had shoots like *Asparagus*, in a week's time no one could have told that they had been moved at all. From experience, therefore, I may say that the season of greatest safety, as regards transplanting trees and shrubs, is not when they are dormant and when life is at a low ebb, but when it is at full tide and growth active; that is the time when an injured tree can most quickly repair the damage which it has sustained; fresh roots will be made in twenty-four hours, under a hot sun and warm soil; whereas, in winter, roots will often languish and die when injured by removal. One more instance, of an exceptional character, which might be dangerous in the case of any hard-and-fast rule respecting the best time for planting, and one which will prove the soundness of the principle carried out in all our best nurseries, and recommended by all planters, requires a passing remark, and that is periodical removals. Thirty large *Deodars*, ranging from 15 to 24 feet in height, and furnished to the ground with branches, some of them with boles as thick as a man's thigh, were, in consequence of the development of certain plans for extension, removed six times within three years, a period of from five to seven months elapsing between each time of removal. The balls were from 6 to 8 feet in diameter! the roots, too, extended beyond the balls, the weight of which necessitated considerable labour to move them, and strong tacking. The first removal was the most difficult, as they had occupied the position in which they grew for some years, and it was then doubtful whether or not the whole of them would live. When the second removal was undertaken, many were of opinion that they would fail; but it was found that, although the branches had not improved after the first shift, the roots had, and they were found to lift much more readily than on

the first occasion. These trees were, however, looked upon as drawing near their last; and, when the third removal was decided upon, an old workman gravely proposed making a fire of them, and a somewhat unceremonious commencement was made in lifting them. This time it was found, however, that the balls were one solid mass of small wiry roots; and, in planting, it was found difficult to get soil intermixed among the fibres. Afterwards the balls became round as cheeses, tough and matted; and the question was not whether these trees would live, but whether it was possible to kill them. I believe, if it had been possible, that laterly we might have pulled them up by the stem, balls and all; yet all these Deodars are now growing, and in good health, notwithstanding their singular peregrinations. Now, as to planting, one of the very first essentials to success is that the soil be trenched and broken up, so that it can be well worked in among the roots, and also that the ground surrounding the latter be well aerated. I prefer, on the whole, high planting; but on very light land, with an open sub-soil level with the surface. The old-fashioned plan of shaking the tree from side to side, and lifting the stem up and down, in order to settle the soil amongst its roots, is, I had hoped a thing of the past; at least, as a rule, I should not recommend it. Thus treated, in puddle, or even in loose soil, roots must as a natural mechanical result get bent and twisted. I prefer placing the tree or shrub in position after the soil in the pit has been brought to the proper level; then stretching every root carefully outwards from the bole, filling in the soil over them—the bottom roots first, the uppermost last—and covering the whole before treading or watering. Some of the soil I leave for a final dressing when the ground has settled down after watering. The staking of newly-planted trees is a matter also of the first importance, for if they are allowed to be blown about by the wind the roots become strained or broken off at the collar. I, however, object emphatically to the driving of a stake down by the side of the stem through the roots and tying the tree to it, because, in the first place, the roots are sure to get injured, and again the stem of the tree is in much danger of being chafed by the top of the stake, or by the tie during wind-waving. Only the other day I saw an illustration of this in the case of two long lines of fine avenue Chestnuts, each of which had four long poles driven in round the bole to serve the double purpose of steadying it, and to prevent cattle from rubbing against it. At the top of the poles, which were 6 feet high, a band of straw had been wrapped round the tree, the poles being tightly bound against the straw by a coil of strong wire. Mechanically the operation had been at first well done, but in the course of time the straw from the wind-waving of the trees had wasted away, and then the stems had become so chafed that only a narrow communication of bark existed, and one of the trees had lost its top by breaking over at the damaged part. The plan which I like best is using three galvanised wires fixed to a collar at a convenient height up the tree, and fastening them to stumps driven into the ground at a certain distance from the stem, thus avoiding the roots altogether. Wire looks better than stakes, and is cheaper in the end, and any kind of stick strong enough may be driven into the ground as a holdfast. Strips of old guano bags make good collars, or rags of any sort, or even straw ropes. Tar cord, instead of wires, is sufficient for small trees such as Cypressess, and Thujas up to the height of 10 feet. For very large trees we employ wire such as is used for fencing. A handy man with a little practice soon becomes expert at fastening trees in this way; he cuts his three wires off to one length, fastens one end of all three to the collar, catches hold of the other, and stooping down with the wire at full stretch, makes a mark on the ground with a finger of the hand which holds the wire; this is exactly the spot where he drives in his stump, with the sharpened end inclining inwards towards the stem of the tree, thus giving greater facility for fastening the wire and placing the stump in an advantageous position like a man pulling at a rope; one or two turns of the wire and an additional blow with a mallet tightens the wire; the other two wires are then served the same and the work is finished. W. D. C.

THESE are 33 agricultural and horticultural colleges in the United States 389 teachers, and 3,917 students.

TOM PUT APPLE AND ITS VARIETIES.

In last number (see p. 24), both Mr. Uphill and Mr. Ellacombe have made a few observations respecting this Apple, which Mr. Ellacombe tells us is plentiful in his neighbourhood. In Somerset, its native county, Tom Put is pretty well known and highly appreciated; but the Apple best known is the one referred to by your two correspondents, and which is what we call, in Somerset, the Colebrooke, the name of a hamlet near Crediton, Devon. Tom Put and it are one and the same variety, which is referred to, at p. 27, by two other correspondents. All these writers describe, as far as they go, the Colebrooke variety exactly, and Mr. Taylor mentions the knobby peculiarity that this tree has along with a few others, such as Manks Codlin, Oslin, White Juneating, and Burr Knot. But, besides Colebrooke, there exists other varieties of Tom Put, one of which I sent you specimens some time ago, and now again send the same sort, which we call the Old Tom Put, so that you may see it is a good keeper, and very beautiful, whilst in pies or puddings it has few equals. Along with Old Tom Put, I also send you the Colebrooke variety, which you will find very small this season, and not so finely coloured as it generally is. I have likewise enclosed four fruits of the same kind, badly coloured, *i.e.*, they have not had sun enough. They serve to show how variable this Apple is in its colouring, according to good or bad seasons. This brings me to a subject I had intended to have written about before, and that is the great likeness of the Colebrooke Tom Put to Hoary Morning, which is another of our beautiful Somersetshire Apples. So like are the two sorts, that I am inclined to think them the same, only I do not recollect that Tom Put has a hoary effluence. If I live to see another crop of fruit, I will minutely watch the two sorts, and report upon them. In the meantime, I may say that I find no other difference between the two, except the bloom. On turning to M. Leroy's useful dictionary of fruits, I observe that the outline figure there given of Hoary Morning is exactly like the specimens of the Old Tom Put sent you; but his description belongs to the Colebrooke variety of that Apple, at least nearly so. Besides the two varieties which I now send you, there are two more Tom Puts grown hereabouts, *viz.*, the White one and the Spicy one. This last is by far the best as a dessert fruit; and, as its name implies, it is spicy and very aromatic. I am sorry I cannot send you specimens of these two last, or of Hoary Morning, having now none left. As a county, I think Somerset stands in the foremost rank as regards Apple cultivation, for, although Devon claims the greatest acreage, we have far finer orchards and orcharding. No other county can show such Tom Puts and Hoary Mornings, or can produce such specimens of Scarlet Pearmain as we can. J. SCOTT.

Merriott, Crewkerne.

[The large, round, somewhat flat-shaped, highly-coloured Apple sent along with this, seems to us to be different from Hoary Morning.]

Ivy and Trees.—I ought, perhaps, to have stated (see p. 546, Vol. VIII.) that my remarks applied only to Ivy-putting where timber is grown for profit. We do not cut it off trees in wild ornamental coverts, nor in the parks. In wildernesses, pleasure-grounds, and in wild ornamental woods it may be allowed limited freedom. It is incorrect to say that Ivy does no harm. In our Oak coppices it has done great injury to the trees and bark; the latter, indeed, is hardly worth peeling off; it is almost as thin as paper, inferior in quality, and costs double the labour to take it off that it otherwise would do. I think it does more harm to Oak trees than to any other, especially young Oak trees. Ivy cutting is a heavy item in our expenses, for it was allowed to grow for very many years unchecked until I came here, and 2,000 acres of Oak coppices are not got over in a very short time. In all judiciously-managed woods that I have seen Ivy is kept in check. Perhaps your correspondent's Apple tree (see p. 4) was too vigorous a grower and required nearly pinching to death to throw it into fruit bearing. Producing wood and growing fruit are widely different subjects.—GEORGE BERRY, *Long-leaf.*

Masdevallia Ehippium.—This is a New Grenadian plant, having large, brownish, bowl-shaped flowers formed of the partly united sepals, the apices of which are lengthened into tails 3 or 4 inches in length. The flowers are solitary, on triquetrous scapes, and of a dull brown colour, the tails being yellow. The leaves are broadly spatulate and very fleshy. This is the *M. Colibri* or *M. Trochilus* of the "Illustration Horticole" (see plate 180), where the flowers are shown of a rich brown colour, relieved by warm yellow lights, and dotted or mottled with dark brown, the outer surface of the sepals being also shown with blue lights. We have seen this plant blooming in Mr. Bockett's collection, and judging from his plant, the "Illustration Horticole" has the more faithful plate of the two. "Botanical Magazine," t. 6, 208.

NOTES OF THE WEEK.

— AMONG choice flowers brought to Covent Garden during the past week we remarked blooms of *Lulia* aneeps Dawsoni, a white variety, and one of the most beautiful and rare of all Orchids; also flowers of *Angreum eburneum*, a noble Orchid, from Madagascar, introduced to our gardens by the late Mr. Ellis. The recent hard weather has had a bad effect on the supplies of flowers for the London market, these being both scarce and dear.

— MR. MAROT, of the "Gardeners' Monthly," Philadelphia, has purchased the "Horticulturist," for some years published by Mr. H. T. Williams, and consolidated it with his own excellent magazine—hereafter, as from its origin, to continue under the editorial management of Mr. Thomas Meenan.

— CALIFORNIA Grapes have been made into raisins with great success and facility, the bunches being simply cut from the Vine and laid in the sun to dry for five days. This kind of manufacture is also a very profitable investment, as while for wine-making the Grapes are only worth about £5 a ton, as raisins they fetch about nine cents a pound wholesale, being at the rate of £50 per ton.

— ON the 22nd of December last a monument was erected in Piro-la-Chaise, Paris, to the memory of M. Barillet-Deschamps, formerly gardener to the city of Paris. The memorial consists of a base surmounted by a large stone sarcophagus ornamented with drapery, flowers, and other emblems, the whole crowned by a bust of M. Barillet. Addresses were delivered by M. Henri Vilmorin, and by other gentlemen, in which the works of the deceased were reviewed.

— MR. T. MOORE, editor of the "Irish Gardeners' Record," has started with the new year an agricultural paper, "The Irish Farmer," which promises well, and is, we think, destined to prosper, and to meet the wants of that class of farmers who cannot afford high-priced papers. The gardening part will, we trust, have a good effect on the farmers' gardens in Ireland, which are in anything but an advanced state.

— AMONG foreign fruits now brought to our markets may be mentioned the Chinese Litchi, which resembles, in general aspect, fruit of the common Plane, and which contains a sweet and agreeably flavoured pulp within a dry husk. Sapucaya Nuts are also plentiful, and are by some considered superior in flavour to the more common Brazil Nut, both being the produce of nearly-allied South American species of *Lecythis*.

— MR. MCINTOSH, of Outlands Park, Weybridge, has sent us plump well-developed seeds of *Lilium aratum* ripened in the open air in his garden at Danevan, an account of which was given in THE GARDEN (see p. 395, Vol. VIII.). It may not be generally known that seeds of this noble hardy Lily grow freely if sown in a raised bed of good garden soil and sand. If sown thinly, the young plants need not be disturbed until they have flowered. Mr. Tillery (of Wolbeck), Mr. Gadd (at Wollaton), and other Lily growers, have raised many seedlings in this simple manner.

— THE annual meeting of the Horticultural Club was held the other day, at the club house, Adelphi Terrace, when the accounts were audited, and were found to be very satisfactory. It was determined that during the winter months occasional meetings for discussion on subjects connected with horticulture should be held, the first being on the 19th, when the principles and practice of pruning will be discussed. The formation of a library was also determined upon, and the committee will thankfully receive any works on horticultural subjects which may be given for that purpose.

— THE friends of Mr. Alexander McKenzie, as a tribute of their appreciation of him, have resolved, on the occasion of his resigning his active duties at the Alexandra Park (although still occupying the position of landscape gardener to the Company), to present him with a testimonial, as a memento of his long and valued connection with the neighbourhood, the various public works he has executed at Alexandra Park, the Thames Embankment, Finsbury Park, &c. Mr. John Bertram, Alexandra Palace, Muswell Hill, N., is honorary secretary to the committee.

— WE have received from Mr. W. H. Watson, of Braystones, near Whitehaven, a pamphlet on "Water in relation to the incrustations of boilers," in which careful chemical analyses are given of waters from different districts, and much valuable information furnished as to their liability or otherwise to produce incrustations. Where carbonate of lime is present, it may be precipitated prior to using the water by adding to it a solution of baryta, varying in strength according to the amount of lime held in solution. One of the best, if not the best process, by which boilers may be freed from incrustation, and one which recommends itself on the important grounds of cheapness, easy application, and general efficacy, is that in which soda-ash, or caustic soda is added to the water. The chemical action consists in the decomposition of the sulphate of lime, the result being carbonate of lime and sulphate of soda.

ÆCHMEAS AND THEIR CULTIVATION.

AMONGST the large number of Bromeliaceous plants in cultivation, there are several *Æchmeas* and *Tillandsias* that occupy a very high position, as well for the varied beauty of their flowers as for the graceful vase-like form of the plants, produced by the peculiarly elegant curvature of the leaves. From the many desirable properties which they possess, it would be difficult to imagine any subjects more worthy of general cultivation. They are easily grown, and, from the moderate size they attain, they are equally suitable for the largest establishments, and for places where the space devoted to plant-growing is limited. The different species flower at different times in the year, thus affording a welcome succession in their blooming; some last in beauty for several weeks; others, like the handsome medium-sized *Æchmea fulgens* and *Æ. discolor*, with their intensely red flower-spikes, remain very attractive objects for months after the actual flowers are gone, their appearance being such as to require close examination, to determine whether the blooms are closed or yet to open. Several of the species are of a partially epiphytal nature, growing in the shady forests between the forked branches of trees, sustained in part by the decayed vegetable matter lodged there, and probably in some cases extending their roots down the trunks to the ground, where they will obtain additional nutriment. From this, it will be easily understood that the roots of these plants do not like to enter soil that is of a close, adhesive nature, requiring it to be the opposite—loose, fibrous, and open—although there is some difference in the ability of the different species to exist in soil of a nature not in accordance with their wants in the above respect. Still, no mistake can be made in growing all the under-mentioned in peat as full of decayed Fern roots, and other vegetable fibre as can be got, in addition to which it will be advisable to add a seventh part of charcoal, or corks broken about the size of Horse Beans; to this put a moderate quantity of sand, and mix the whole well together; in this they will not only make roots freely, but the roots will live much longer—a circumstance that has much to do with the number of suckers the plants are able to throw up after flowering, and on which in a great measure depends the rate of increase in subjects of this nature that are slow to propagate. The several species push from the base of the full-grown plants, about or after the time of blooming, suckers like most Bromeliads. These should be allowed to remain upon the old plants until they have attained a considerable size—say one-sixth that of the crowns from which they spring. It is important to leave them attached to the parent plant until they have got something like the above size, as if removed too young they are long in making much progress. When thus allowed to attain a fair size before being taken off, they will generally be found to have a number of roots just breaking through the bark at the base. The suckers will usually be in a condition to take off in the autumn; slip them off with the fingers, being careful not to injure the incipient roots, or they may be taken off with the help of a sharp knife. In this condition they will root into the soil immediately, putting them singly in from 3-inch to 6-inch pots, according to the size of the suckers; drain the pots well, and for this first potting sift the soil, forcing all the fibrous portion through the sieve, and add more sand (about one-fifth) than will be required when the plants get larger; give a moderate watering at the time they are put in, and place them at the warmest end of the stove, in a temperature of 65° or 70°. If a little bottom-heat is at hand, it will assist the formation of roots; but do not cover them with a propagating-glass, as the hard close texture of the leaves is of a nature that allows little loss by evaporation, consequently they do not flag when exposed in the atmosphere of most things, as would be the case with ordinary cuttings of most things. Kinds such as *Æ. fulgens*, that form a few inches of stem below the point where the leaves are emitted, simply require inserting in the soil up to the base of the leaves; in the case of species that do not make any length of stem it will be necessary to strip off a few of the bottom leaves before putting them in. Keep them through the winter in a night temperature of 60°, with 5° higher in the day; place them in a light position, and let the soil be moderately moist. By the beginning of March, as the days get longer, raise the temperature 5° during

the night, and 10° during the day; about the end of the month move them into pots 1 or 2 inches larger, according to the size of the plants, using the soil in a rougher state, and adding crocks or charcoal, as already advised. The pots must be well drained, and must not be used too large, as the whole of the different species do not like too much root room. When the sun gets more powerful, shade will be required in the middle of the day. By the beginning of May the temperature should be increased to 70° or 75° in the night, and proportionately higher by day, giving air in good time, but closing early in the afternoon. A slight syringing at the time of shutting up will assist growth. Continue this treatment through the summer months, always keeping the soil moderately moist, as, if allowed to become dry at any time, the plants will be injured. At the end of August disperse with shading and give more air; as the autumn advances reduce the temperature down to the point recommended for the season previous, and winter similarly. As the days lengthen increase the temperature, and move them into pots 2 inches larger, using the soil in a more lumpy state. Treat as in the preceding growing season as to heat, shade, and moisture. In the course of the summer the plants will push up their flowers, and as they open may, if required, be placed in a warm conservatory, but must not be set where they will be subject to a current of air, neither must they be exposed to the sun. When done blooming move them back to the stove, and treat them as before. Suckers will now be formed, and, when large enough, should be taken off and treated generally as already advised. The old plants should be kept, and, if well cared for, will through the spring push up more suckers, that can, when they have attained sufficient size, be taken off and struck as recommended for those first produced. The following species of *Eichmea* and *Tillandsia*, though differing much in size and general appearance, will all succeed under similar general treatment; of course, proportioning the diameter of the pots in which they are grown to the size to which the different kinds naturally attain. At the head of the list stands the splendid

Eichmea Mariee Reginae, a truly regal plant of comparatively recent introduction. It is a native of Costa Rica, and is of stately growth, the leaves 18 inches in length, gracefully curved. From the centre springs the flower-spiky, from 20 inches to 2 feet in length. It is erect, and partly clothed with ample deep rose-coloured bracts, which retain their colour for several months. The flowers are tipped with blue, and as they get older change to a salmon colour. This magnificent plant is yet rare. It flowers in July.

E. fulgens.—This has a much smaller flower than the preceding, and is from Cayenne. It bears bright red erect flower-spikes, that have the appearance of branching sprays of coral, which last and retain their colour for months after the flowers are gone. It is one of the best comparatively small decorative plants in cultivation. When grown in 6 or 8-inch pots it is especially useful for standing during the summer months in a conservatory, where its intense colour contrasts well with that of other plants.

E. fulgens discolor is a variety of the above, requiring similar treatment.

Tillandsia Lindeni.—This, one of the most beautiful of small-growing plants, is a native of Brazil. The leaves are prettily curved; the flower-scape rises for a considerable height, and is rosy-carmine in colour; the flowers are proportionate to the size of the plant, and are of the most vivid blue with a white eye.

T. Lindeni major is similar to the above, but has larger flowers. Both bloom in the summer, and do not require large pots.

T. splendens.—This is a plant of smaller growth than *T. Lindeni*, with short, blunt, recurved green leaves, barred with deep brown; the scape is bright red, the flowers white. It is handsome in or out of bloom, and does not require a pot over 6 or 7 inches in diameter. It flowers in the early part of summer.

Insects.—*Eichmea* and *Tillandsia*s are not very subject to the attacks of insects. Mealy bug and scale will live upon them, but the texture of the leaves is such as to admit of these being easily removed by sponging and a free use of the syringe. T. BAINES.

HUSKLESS CHINESE WALNUTS.

In a paper upon the natural history of southern and eastern China, published in the seventh number of the "Journal of the North China Branch of the Royal Asiatic Society" (Shanghai, 1873), the Abbé Armand David has given a brief sketch of the fauna and flora of those portions of northern and western China which he had visited. He observes:—"Some portions of the province of Pekin furnish Walnuts which have no husks. After several fruitless enquiries, Dr. Bretschneider procured specimens of these huskless Walnuts, of which he was so kind as to furnish some for my examination. They are of two sizes, the smaller measuring one inch, the larger one inch and a-half in length. The Nuts are rather thinner and more brittle than in the common Walnut, and their surface is curiously and irregularly eroded, presenting very much the appearance of sea-worn rock; the outer polished coat, in fact, is partly wanting and partly separable from the inner thin part, which it covers only in patches, and pieces of it can easily be detached by the nail. They show a tendency to split longitudinally at the side of the thickened keel formed by the junction of the valves; and the small-sized nuts (which are much thinner, indeed sometimes little more than coriaceous-cartilaginous in texture) along the middle of the valves also. Vertical and transverse sections exhibit the thin septa, and in all respects the structure of the ordinary form of *Juglans regia*, Linn., of which this is doubtless only a singular monstrosity. Except in size and the texture of the shell, I do not find anything to distinguish the two kinds of Nut sent, and this tends to show that too much stress must not be laid on size, or I may add form either, in attempting to discriminate species in this genus. M. Maximowicz has himself, whilst describing and figuring with his usual care the Eastern Asiatic forms he had examined, explained that their specific distinctness is at present uncertain. Dr. Bretschneider says this curious fruit is cultivated in the mountains to the north-east of Pekin. Neither Loudon in the "Arboretum," where thirteen pages are devoted to the Walnut, nor M. Casimir De Candolle in his "Mémoire sur les Juglandées," or in the monograph in the sixteenth volume of the "Prodromus," makes any allusion to a variety or monstrosity in which the epicarp is suppressed. There is no reference to such a deformity or abortion in Moquin-Tandon's "Téatologie végétale;" nor, indeed, says Dr. Hance, in the "Journal of Botany," though I do not pretend to have made a thorough search, have I been able to find a parallel instance mentioned of any single genus, in the books to which I have access. It seems, therefore, worth putting on record, if only for its singularity.

Prices of Nuts, Apples, and Pears.—According to Mr. Webb's account (see p. 40), there is a chance of realising a fortune by growing these fruits, provided the soil and locality are suitable for them after they come into what he terms "bearing order;" but what I want to know (allowing the trees to produce the quantities stated) is, where I can realise the prices quoted; such returns cannot be obtained in Covent Garden Market this season I am sure, as I can buy Cob Nuts at from 6d. to 8d. per lb. retail, or, rather, I could a few weeks back, and the highest prices that Apples of good quality, such as the Wellington and Blenheim, have realised, have been 4s. per bushel, and there has been a difficulty to obtain 3s. for anything inferior to these sorts. Pears, too, have been almost as bad. If Mr. Webb can inform me where such prices as those quoted can be realised I shall be grateful.—W. J. M., *Broadlands, Enfield.*

Town Gardening.—Having had a good many years' practice, I can fully endorse all that Mr. Anderson has said upon this subject. It is seldom the case that any system of culture is carried out in town gardens; in short, in place of neatness, which is, above all things, requisite in small gardens, untidiness is their prevailing characteristic, and instead of a few blooming plants and shrubs, Groundsel and other weeds often constitute the only kind of vegetation to be found in them. Nevertheless, considerable sums of money are sometimes spent on such gardens, but seldom in the right way. As regards the cost of keeping a suburban or town garden neat and tidy, size is generally the criterion; but I may safely say that from 10s. to £3 10s. per month will be the cost (according to size) of ninety-nine out of a hundred, taking the average run of the houses; but, of course, if glass has to be attended to, more cost will be incurred. As to plants, it is sufficient to say that a very large proportion of those sold by hawkers are grown to sell, and, as a rule, it is far better to deal with a nurseryman or gardener, who has a position to maintain, than obtain them from a man whom we may never see again. As to the class of plants used, that must depend on the amount to be expended; but, as a rule, expensive plants are not necessary, neither is it advisable to use any but such as stand smoke well, unless quite away from the town properly so called.—W. J. MAX.

When are Oranges fit to Gather?—Would some of your correspondents inform me, through THE GARDEN, how I may know when Oranges are fit to gather for dessert, and how long they take to ripen from the time the fruit has set?—B. C. J. W.

DINING-ROOM DECORATION.

A VERY effective centre-piece for a dinner-table may be made by arranging a variety of fruits in Moss around the roots of a plant, either in or out of its pot. Palms, broad-leaved Grasses, and other

plants, with graceful foliage, will bear being turned out of their pots without being injured by such treatment, provided their roots are quickly surrounded with damp Moss, and are thus not left exposed to the prejudicial influences, as far as they are concerned, of light and air. But plants in flower are very liable to shed their blossoms if their roots are in any way disturbed or exposed. The accompanying engraving shows one out of many ways of carrying out an arrangement of this description. The group here depicted is dressed to one face for a sideboard, and, upon a piece of furniture of a suitable size, has a very noble appearance. Palms, such as *Geonoma gracilis* and *Cocos Weddelliana*, or such Grasses as *Gymnothrix latifolia*, together with *Draconas*, *Cordylines*, and other similarly graceful plants, are the best forms for this purpose. Any objectionable straight lines in their stems may be broken by sprays of climbing Fern, *Myrsiphyllum*, or *Fiens minima*. If the decorator should not be provided with two semicircular zinc trays, which, when placed together, form a ring around the pot of the plant, substitutes for this convenient contrivance will readily suggest themselves; and, when filled with Moss, and covered with fruit and Fern fronds, no one need know whether tumblers or finger-glasses, whether Strawberry punnets or soap dishes form the circle at the base of the centre-piece.

An ingenious decorator is rarely at a loss for ways and means in the matter of receptacles for flowers and fruit, and many unexpected articles would present themselves to some people, if they were "behind the scenes" in table-decoration. The cook is laid under contribution for patty pans, dariole moulds, &c.; the housekeeper wonders what has become of her

jelly glasses and salt cellars; and the butler misses sundry articles in his department, for some, if not all, of these are very likely to be helping to produce the much-admired general effect as regards decoration. If a centre-piece of this description is required for the

middle of a dinner-table, such large fruits as Pines and Melons should not be used in it. All other kinds of fruit may take a part in an arrangement of this kind, and it is not necessary to confine the selection to eatable fruit; thus the sombre hues of Figs, Filberts, Russet Apples, and Beurri Pears, may be relieved by the more showy colours of the fruits of *Solanum capsicastrum*, *Physalis Alkekengi*, Holly, Arbutus, or Berberis, or by the scarlet seeds in the opening pods of the common yellow Iris. Such a group as this, arranged upon a small revolving dumb waiter in the centre of a dinner-table, presents a different outline to every guest; and if it be turned, very slightly at a time, several times during the dinner, every one has an opportunity of seeing a different view of it every time it is moved. W. T. T.

Centre-piece for a Sideboard.

COLOURS BY GASLIGHT.

In the arrangement of floral decorations for ball rooms or large assemblies of that kind, it should be borne in mind that they are mostly seen under strong artificial light, and that the amount of success attending the arrangement will greatly depend upon the selection of suitable colours for the occasion. Much as we admire the delicate markings of individual flowers by daylight, or the vein-like variegation on particular leaves, it by no means follows that flowers or leaves possessing such characteristics would be the most effective under the artificial light to which they would be subjected. I find that flowers of decided self-colours, such as the Calla, in the case of white flowers, and the Poinsettia, in that of scarlet, are even more effective under artificial light than during the daytime. But the blue Eranthemum, the purple Lasiandra, and all

flowers, with mixed colours, are not nearly so effective under artificial as under daylight, while, as regards foliage, nothing surpasses the soft green of *Lycopodium denticulatum* for edgings or flat decorations, and Palms and plants of that kind for more lofty forms of decoration. All shades of green are effective, but in the case of variegated leaves the colours must be well defined to look well, as, when mixed in the leaf like those in the *Abutilon Thompsonii*, they have a sickly look. Partially shaded recesses should have a cool groto-like appearance, and should be filled with Ferns and similar plants, while flowering plants and those possessing bright foliage may be more effectively grouped in more exposed situations under strong light. For the base of mirrors or window recesses, a bed of green Moss or *Lycopodium* and dwarf flowering plants, such as *Primulas*, *Cyclamens*, and Dutch bulbs look well. These and small Ferns, *Isoplepis*, and *Panicums* form a verdant spring-like combination. In wreathing walls of ball-rooms, great care should be exercised, as a too liberal use of wreaths, especially if at all bulky, gives a heavy sombre appearance to the room, and apparently reduces its height. Nothing that we have tried is so effective in all respects as long sprays of common Ivy, carefully removed from trees or walls, with the slender side-shoots intact and placed in its natural position, end to end, gradually reducing the size of the pieces towards the top of the room. In corners, round doorways, and in similar positions Ivy in this form may be used with advantage; it is light and natural, and lasts fresh for a long period. JAMES GROOM.

HEATED PLANT CASES.

I HAD for some years a plant case, 5 feet by 1 foot 6 inches, and 2 feet deep inside measure, heated by means of the following arrangement, which was perfectly successful, and, taking into consideration the fact that flowering plants are for many reasons unfit for small cases, where they would have to remain the whole year, I had no difficulty in growing anything I wished:—The bottom of the case was wood, 5 inches deep inside, and lined with sheet zinc. Close against the bottom corner all round, I fixed a 1½-inch wrought-iron gas-pipe, not in a complete ring, but closed where the two ends of the coil met. One end was turned up, and formed into a wide tube, to hold the excess of water from expansion, and to admit of filling, to compensate for loss by evaporation. From the lower side of each end of the coil descended two half-inch pipes, which were connected, one to the top and one to the bottom of a hemispherical copper boiler, 5 inches in diameter, 4 inches deep, the flat side being downwards. The holes, through which the pipes passed in the bottom of the case were rammed tight with soil, to prevent the fumes of gas entering. At first, I had a common floating night-light (oil); but this was afterwards replaced with a very small gas-burner, such as is ordinarily used for lighting purposes, consuming about one half cubic foot per hour. The plants were always kept in pots, or baskets, as, on account of the drawing towards the light, they need frequently turning round; and, also by re-arranging the plants, different effects may be produced. I tried Orchids for two years, but, although they grew tremendously, they did not bloom; and I, therefore, sold them, making a good profit, owing to their great increase in size. I then stocked the case with dwarf Palms, *Dracaenas*, *Cyperus alternifolius*, and plants of that class, which were so satisfactory, and so little troubling, that I adhered to these almost exclusively for some years, exchanging the plants to advantage when they grew too large. The plant which gave most trouble was *Cyperus alternifolius*. It grew so large as to require dividing several times during the year, and numbers of large plants of it had to be thrown away for want of room. The case was afterwards removed into a warm room, which was constantly in use, and the heating arrangement was found then to be of little use, and was discontinued. To the best of my recollection, the cost of making the heating arrangement complete was about 22s. This was some ten years ago. No doubt it would cost twice the money now; but it was altogether a satisfactory arrangement, and gave no trouble in use. THOS. FLETCHER, F.C.S.

Salvia Bolivienis verticillata.—This is one of the best of *Salvias* for winter flowering. Its brilliant scarlet blossoms are produced in whorls of eight to each spike. As is the case with *Primula japonica*, it continually throws out flowers from the whorls, and also freely from the laterals; and, if kept damp at the roots, it will remain in bloom for a considerable time.—R. H. B.

Seedling Beech for Hedges.—A peculiar character belonging to the Beech is, that whereas large trees drop their foliage in autumn, young plants, or those kept dwarf by cutting, retain it in a dry state until the young leaves are budding forth in spring. This renders them excellent subjects for hedges in nursery grounds or similar situations, where shelter from wind is desirable, or for forwarding early crops of vegetables.—J. GROOM.

THE INDOOR GARDEN.

SPRING PROPAGATION OF BEDDING PLANTS.

To raise a healthy progeny from unhealthy parents is just as difficult in the vegetable as in the animal kingdom; therefore, at this season, when going through the stock, it is far better to discard all weakly unhealthy plants, and thus leave more space for such as are robust and vigorous, than to retain them. Soft-wooded plants, if healthy, when placed in a temperature of about 60°, as the days lengthen make growth with surprising rapidity, and a very large number may be thus raised from a comparatively small stock. As regards the best means for propagation, few places are so well provided as they ought to be; and at the present time, in many private gardens, large numbers of plants for summer and autumn decoration are produced with very limited means. *Verbenas*, *Fuchsias*, and many other soft-wooded plants may be rooted with ease in pans of sand and water in from four to six days, placed on a hot flue, or any other warm surface, and kept close. The pans should be filled about two-thirds full of sand, and then just flooded with tepid water, the cuttings being laid with their bases just resting in the sand. One advantage this plan has, and that is, a very large number may be quickly rooted in a small space. As soon as roots are formed they must be dibbled into boxes of warm soil, and placed in a temperature of 60° to 65°, until established, and then moved on into cooler quarters; and so, in this way, where large numbers are required, a continual stream of healthy little plants is manufactured, and hardened off, by planting time. Another way—and one which I think is better, where one has the luxury of a propagating-house, however small—is to have a wrought-iron tank fitted on one side of the house, and a slate shelf, or stage, on the other. The tank should have a division down the centre; and a flow-pipe should be connected with one side, and a return pipe with the other, so that the heated water could flow round. The tank should be covered in with stout builders' slates, and have about 6 or 8 inches of sawdust, that has laid in a heap some time, placed on the top, and pressed down. As soon as the heat is fairly up, which will be in a few hours, a sprinkling of sand may be placed on the top, and the cuttings dibbled in. I believe this to be about as perfect a plant manufactory as can be devised, and—all things considered—as cheap; for although, in the first instance, an iron tank may be expensive, it will be practically indestructible, which is more than can be said of most materials nowadays. One of the reasons why sawdust is so valuable for purposes of propagation is, it is so easily kept in a regular state of heat and moisture without having frequent recourse to the watering-pot, and it is in this particular that the inexperienced so often fail. I need not say how valuable a bed of this kind would be after the spring stock was worked off for filling up again with *Begonias*, *Justicias*, *Poinsettias*, and other soft-wooded plants that are found so useful in winter for the conservatory and drawing-room. At other seasons, even in the winter, *Dracaenas*, *Ficus elastica*, &c., might be rooted with certainty under such conditions. I have now a batch of *Ficus*—well-rooted little plants—that were put in a sawdust bed in the stove, in the form of single eyes, with a leaf attached to most of them. They were simply pushed into the moist warm sawdust thickly, less than a month ago. Of course, if anyone prefers having their cuttings in pots the sawdust then forms an excellent plunging material, always moist and steady in temperature. In these days, when both skilled and unskilled labour is advancing in price, a tank and bed of this kind effects a great saving, inasmuch as the cuttings are simply dibbled into the bed, and, as soon as rooted, are lifted carefully out and dibbled into boxes, thus doing away with the use of pots altogether. At least, in the case of bedding plants. Formerly, when it was the custom to pot off most kinds of plants, pots constituted a large item in the garden expenditure. E. H.

Strelitzia Reginae Planted out in Conservatories.—Although generally grown as a stove plant, I find that this *Strelitzia* succeeds admirably planted out in conservatory beds where it gets plenty of root room, and an intermediate temperature. Under such

conditions its foliage becomes large and effective, and the flowers are proportionally increased in size. Although this *Strelitzia* is not particularly serviceable as a decorative plant, in a small state it is highly effective; when well established in conservatory beds its peculiar colour and singular form of flower arresting the attention of every visitor, and well established plants are seldom without expanded flowers.—J. GIBSON, *Henham*.

ALLAMANDAS.

THESE are magnificent free-flowering plants, natives of South America. Their large trumpet-shaped, yellow blooms are produced in great profusion during a long period of the year, and when well-managed, they can be had in flower from April until late in the autumn. They are especially useful on account of the many ways they can be grown, succeeding well as trained pot specimens, and also as roof climbers, planted out, or in pots. Their long uninterrupted habit of flowering renders them equally suitable for being grown in either way; the flowers are likewise well adapted for cutting, their colour harmonising agreeably with most other plants. They increase readily from cuttings of the half-ripened shoots, inserted in sand, with brisk heat in a propagating frame, or under a bell-glass; they can be struck at any time of the year when shoots can be obtained in the above condition; but about the beginning of March is the best, as then it gives time for the young plants to make considerable progress before the autumn. Put the cuttings singly in small pots; they will root in a month, when they should gradually be inured to more air, and, as soon as they have got fairly established, move them into 6-inch pots. Allamandas do best in good fibrous loam, to which add a moderate sprinkling of sand, and about one-sixth well-rotted manure; mix all together, using it for the plants in this stage moderately fine, pressing the soil firm in the pots; now place them where they will get plenty of light, in a night temperature of 70°, with a rise of 10° or 15° during the day; pinch out the points of the shoots, so as to induce the lower eyes to break, and give water all through the growing season, before the soil gets so dry as to cause the young growth to flag. Give a moderate amount of air in the middle of the day, and syringe every afternoon; but no shading is required, as all the species of Allamanda do better without it, making shorter-jointed stouter wood under the full influence of the sun, which does not injure their leaves if the glass is of good quality. Through the summer months the temperature should be 5° higher both day and night. By the end of June, the pots will be filled with roots, and they should be moved into others 3 inches larger. At this shift give ample drainage, using the soil in a more lumpy state, breaking the fibrous, turfy parts into bits about the size of Walnuts; again press it quite firm in the pots, as these plants will not do with it in a loose condition. Place four or five neat sticks in the pot; to these train the shoots, the points of which again pinch out to get them to break, and continue the treatment as to heat, water, and syringing overhead until the middle of September, when discontinue the use of the syringe; admit more air, and do not give water to the roots until the plants flag considerably; this will check further growth, and help to harden up the wood. Keep on treating in this way till the end of October, allowing the soil to become a little drier each time before water is given, so as to ripen the leaves; many of the earliest formed will now turn yellow, fall off, and little more growth will be made. The temperature for the ensuing ten weeks may be reduced to 60° in the night, with 5° more by day, only just giving as much water to the soil as will keep the green leaves towards the extremities of the shoots from shrivelling. Place the plants during this their season of rest at the coolest end of the house.

About the middle of January remove all the green shoots, cutting back into the ripe wood; turn them out of the pots. From the little water given for some time back the soil will most likely be very dry. To ensure its now being thoroughly moistened, immerse the balls in a pail of tepid water until the whole is wet through. If this is not done the new soil in which they are about to be potted will get saturated by the water required to moisten the ball through to the centre. After this is done return them to the pots in which they have been growing, and place them for a day in the stove to allow the water to drain off; then remove the old drainage and any loose soil that there may be about the surface, and at once put them in their flowering pots (these may be from 15 inches to 18 inches in diameter). Place in the bottom 3 inches of crocks to secure sufficient drainage, as they will need a deal of water. The soil should be similar to that already advised, but will be now all the better for being a little more lumpy. Use the potting lath freely, so as to ram it quite hard. These plants require the soil to be made as close as possible, more so than almost any others grown in pots. The best method of training Alla-

mandas and other subjects of similar habit, when grown as pot specimens, is on a stout iron wire trellis, secured to three strong stakes inserted in the soil placed just within the rim of the pot. Such a trellis, 4 feet high by 3 feet in diameter, will be big enough for a large plant. As soon as the plants are potted, fasten the trellises in their places, and at once train the shoots to them, dispersing them evenly over about two-thirds of the lower parts; if they are tied over the top they naturally push the young growth from that point, and in afterwards bending them down to cover the trellis they are very liable to break out. The reason why Allamandas should be so far differently treated than most things, in cutting back and potting them before they have made any growth, is that the young shoots are so brittle that, in training them on the trellis, these are likely to be broken off, and the plants are naturally such free growers that it does not interfere with their after progress. When the potting is completed, instead of plunging them in a bed of tan, or other fermenting material, at a considerable distance from the light; they should be elevated on inverted pots as near the glass as the trellis will admit of. So placed the shoots will grow short-jointed and stout, the reverse of what they will be if stood further from the roof. Syringe overhead every afternoon. They will break into growth in about a fortnight; and as the young shoots advance keep them tied to the trellis in an upright position, as, if bent down before the bloom is well set, it induces them to break back, the points generally ceasing to push much further, which causes delay in the time of their flowering; as also a reduction in the quantity they will produce. As the advancing shoots require more head room, the plants must be regularly lowered, so as just to keep the points from touching the glass. At the beginning of March raise the temperature 5° in the night, allowing it to run up considerably with sun heat in the day. By the middle of the month, when the weather is very bright, it may be necessary to give for a short time in the middle of the day a little air by opening the ventilators about an inch or so; this will be enough, as if too much is admitted it will seriously affect the young tender growth. It is at this season that careful attention is most essential to anticipate the rise in temperature through the sun's influence in fine weather by timely stopping the fires. It is an indication of the worst possible management in the cultivation of stove plants to be under the necessity of admitting large volumes of cold external air in the spring to keep down the temperature sufficiently through the inconsiderate use of fire heat. If a little air is given as above advised, when the thermometer rises to 80° in bright weather, no harm will be done by its going up 6° or 8° higher, if the atmosphere is kept moist, always closing the house sufficiently early and setting the fires going so as not to allow the heat to fall too low. As the soil becomes filled with roots the plants will require a copious supply of water and a free use of the syringe overhead. Towards the end of the month, if all has gone well, every shoot will have its point set with flowers; it is better to defer training until the blooms begin to open, after which the shoots ought to be carefully wound round the trellis, so as to distribute the flowering points evenly over it.

They will now need water almost every day, giving liquid manure two or three times a week, continuing the use of the syringe, which will not injure the flowers. The night temperature may now be kept at about 75°, with a rise of 10° in the day. They will quickly push up another lot of shoots, which, when commencing to bloom, should be trained as were the preceding; they will thus keep on through the season. Give more air and less fire heat as the summer advances. By the end of June the plants may, if required, be removed to a conservatory and placed where they will not be under the influence of a draught of external air; here they will form conspicuous objects until the middle of August, when they should be returned to the stove, where they will, if wanted, continue to flower for some time, after which they should be gradually ripened up, partially dried off as in the preceding autumn, and rested similarly. In January, as before, cut them back, and shake about half the soil from the ball, reducing a portion of the roots. Re-pot with new soil, and treat in every way through the season as advised previously. So managed the plants will last for many years. Allamandas are amongst the best of stove climbers, for which purpose they require to be treated as for trained plants, except dispensing with the trellis, and not stopping the shoots further than to induce their breaking, so as to furnish the allotted space; they should be freely cut back every season before they are started into growth. From their very strong habit of growth, even when required as climbers, it is better to grow them in pots than to plant out, unless they are wanted to cover a very large space, in which case they may be turned out in a border of limited extent, and the soil partially renewed each spring. The following kinds are all well worth growing:

A. nobilis.—A strong grower, with very large, finely-shaded, bright yellow flowers; requires a light situation to bloom it freely.

TREES AND SHRUBS.

LEBANON AND ITS CEDARS.

The following notes on the Cedars of Lebanon, taken at a lecture, delivered in 1861, by Dr. Hooker, shortly after his return from Syria, may interest other readers besides Mr. Cornhill. I am not sure whether these lectures (there were three of them altogether, on the vegetation, &c., of Palestine) were ever printed; but Richard Oldham, who fell a victim to dysentery in China, and I, made a joint report, which I have preserved. The part relating to the Cedars on Mount Lebanon is, in substance, as follows:—The lower slopes of the southern Lebanon reach to within a few miles of Beyrout; the intervening country being dry and sandy, and the vegetation in consequence very scanty. The sea voyage to Tripoli (the nearest landing place to the Cedars) from Beyrout occupies about eight or nine hours, but in making the journey by land from the latter place, it took them (the late Mr. Daniel Hanbury was Dr. Hooker's fellow traveller) three days, although they rode twelve and fourteen hours a day. The length of time consumed in this journey was caused by the circuitous and hilly nature of the route they were obliged to take to reach the Cedars which lie in a north-north-east direction from Beyrout. The travellers encamped three days under the only group of Cedars supposed to be left standing on the Lebanon lying nearly due east from Tripoli.* From the Cedars, which are at an altitude of 6,000 feet, they made two excursions to the summit, the highest point here being 10,500 feet above the level of the sea. The Cedars, considered in their relations to other circumstances, afford some very instructive ideas. So far as the lecturer could ascertain from other travellers, and from his own observations, this is the only remaining group of Cedrus Libani standing on the Lebanon, though it is abundant on the Taurus, in Asia Minor. This group stands in a gentle undulating plain, of about 6 miles in width, and the trees are in several clusters or clumps, scattered over an area of about 3 or 4 acres. The trees are all growing on raised mounds of stones and detritus, called moraines, which affords them perfect drainage, thereby giving us a hint to plant Cedars in well-drained soil. The entire group consisted of about 400 trees. One of the largest measured over 40 feet in girth, and it was supposed that it could not be more than 400 years old. There were many small trees, but none of them were less than 8 inches in diameter, and probably none under forty years of age. The inferences respecting the age of the trees were drawn from counting the concentric rings in a tree (26 feet in girth) which was felled. The lecturer was decidedly of the opinion that all the trees in the group were, taking the extreme limits, between the ages of thirty-five and 400 years. Hence no credence could be given to the statement put forward by certain writers, that trees dating from the time of King Solomon were still in existence. Although thousands of seeds are produced every year, many of which fall to the ground, and even germinate, yet there are no plants younger than the age mentioned, owing to the dry heat prevalent in spring and summer, which scorches up all herbaceous vegetation. It is probable that, at the date of the youngest trees, there was a very wet season, or a succession of wet seasons, that enabled them to make their early growth. The wood of these trees was found to be a little more highly-coloured and closer grained than that of trees grown in this country, attributable, doubtless, to the slower growth of the former.

Enumeration of the Trees.—Clump 1.—Total number of trees thirty-seven. One tree 5 feet in diameter, thirty-six from 6 inches to 4 feet. This clump is long and narrow, sides steep, dovetailing into the surrounding clumps. Clump 2.—Total number of trees, ninety-five. One tree, 40½ feet in girth, one 13 feet in diameter, one 11 feet, one 10 feet, one 6 feet, two 5 feet, eighty-seven 1 to 3 feet, and one 6 inches. This is the largest clump. On east side a chapel and a small out-house. The oldest trees are apparently here. Clump 3.—Total number of trees eighty-five. One tree, with split trunk, 37½ feet in girth; one solid, 28½ feet; one 8 feet in diameter, two 7 feet, one 5 feet, seventy-nine 6 inches to 4 feet. Clump 4.—Total number of trees seventy-one; all from 6 inches to 4 feet in diameter. This is the most circular clump. Clump 5.—Total number of trees seventy-two. Eleven trees are 4 feet in diameter, sixty-one from 6 inches to 3 feet. Clump 6.—Total number of trees twenty-five. One tree 5 feet in diameter, nineteen 1 to 4 feet, five under 1 foot. Clump 7.—Total number of trees, four. Clump 8.—One tree. Clump 9.—Total number of trees, eight.

W. B. HEMSLEY.

Sea-shore Live Oak.—"V." enquires what the Sea-shore Live Oak of America is. It is *Quercus virens*, an evergreen species of

* I have some recollection of reading of the discovery, subsequently, of much more extensive Cedar woods in another part of the Lebanon.—W. B. H.

A. Chelsoni.—A profuse large-flowered kind, from Western Africa, almost as deep in colour as *A. Aubletii*, and has not the objectionable habit of the blooms reflexing, natural to that variety which it supersedes.

A. Hendersoni.—A very strong-growing, large, free-blooming sort; the base of the flowers internally suffused with brown.

A. Schottii.—A very strong grower, with immensely large pale yellow flowers that reflex a good deal. It is not so free in blooming as the others.

A. cathartica.—A well-known free flowering kind, with moderate-sized blooms, which it produces plentifully.

A. grandiflora.—A magnificent sort with beautiful bright canary-yellow flowers, produced in large quantities. It is very distinct in habit, and a much weaker grower than all the others, with smaller foliage, and is the most suitable for growing as a pot specimen, in which way it may with advantage be trained to sticks, dispensing with a trellis.

Insects.—Allamandas possess almost an immunity from insects, except a minute yellow thrips, which is very troublesome if once it gets a footing, as it destroys and disfigures the young flower buds and leaves. It is easiest kept under by copious and daily syringing, as it is most difficult to kill by fumigation. T. BAINES.

IXORAS AND OTHER PLANTS AT BANGALORE.

In your last number (see p. 20) Mr. Baines gives an account of the best method of cultivating *Ixoras*, which, he says, "to grow well, must be subjected to as much heat as any plant in existence during the spring and summer, and to a temperature not lower than 65° in winter." He further states that "neither the atmosphere nor the roots should be allowed to get too dry." In the same number I gave a brief description of the climate of Bangalore, and it may not be uninteresting to know that *Ixoras* grow there as bushes (out-of-doors, of course), without any care or attention whatever. *I. coccinea* is, perhaps, the handsomest, and even, under such neglect, the blooms are very fine, but there are three or four others, the particular names of which I do not recollect, that bloom just as freely. During the whole of the hot dry weather, from February to May, these plants withstand the drought wonderfully, enjoying practically, in this way, a season of rest, and blooming freely after the first showers and during the monsoon. The *Ixora* at Bangalore is a hardy shrub. The *Tabernaemontana* is another that blooms continually in a very profuse manner, without the least care being taken with it, and the same may be said of some of the *Allamandas*, *Jatropha multifida*, *Poinciana pulcherrima*, *Poinsettia*, *Cassia*, *Fistula*, which, however, is more than a shrub, and a great many others. Even under such neglect the bloom is abundant and of long duration, but this does not justify the neglect, even though a *Poinciana pulcherrima* shrub was observed to last in continual flower, day after day, for more than five consecutive months. Greater attention is now being paid to the shaping and cultivation of these "common or jungle plants," as they are not unfrequently called, with the special object of improving them and obtaining new varieties of them by skillful hybridisation. With the intelligent care that is being exercised in this direction there is no doubt that many a plant and shrub, now considered as out of place in a garden, will soon find an appropriate habitat there, and that horticulture generally will receive the attention which it deserves. There are probably few places where the climatic conditions are, on the whole, so favourable for advantageous cultivation, with a minimum of trouble, of a wide margin of plants between the alpine and the tropical flora, as Bangalore. The only wonder is that the neglect of these opportunities has been so great. Writing in the thick of a London fog, and in admiration of what is done under the difficulties of an English climate by professional and amateur gardeners, the wonder is greatly increased. J. P.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Germination Within the Fruit.—Can any of your readers recall an instance where germination has occurred in seeds in the Cucurbitaceae or other Orders within the fruit, and, if so, under what conditions?—D. D.

Coprosma Baureana variegata.—This useful plant is not only very effective in summer beds, but is one of the best plants that can be employed at this season for edging plant-stands, jardinières, or edges of conservatory stages. Its bold, distinctly variegated foliage and trailing habit render it a most desirable subject where decorative plants are in request during the winter months. It succeeds well in a cold house.—J. Groom.

Fungus on Date Palm.—With this I enclose a leaflet of a Date Palm for your inspection—you will observe upon it something like the spores on the back of a Fern frond. Would you kindly tell me what they are? The Palm in question was sent to me along with some other plants from Mentone last April; all its leaves were covered with spots similar to that I send, but the growth it has made since it came is clean and healthy.—W. W., *Baylehurst*. [It is a Fungus very common on the older leaves of the Date Palm.]

Oak not often seen in this country, although it was first introduced nearly 150 years ago. It is only in the southern Atlantic states of North America that it attains the dimensions of a timber tree, and it never grows to a large size; but it has the reputation of being stronger for its size than any other Oak. Northwards it dwindles down to a mere bush, and gradually disappears altogether.—W. B. HEMSLEY.

HINTS ON PROPAGATING CONIFERS.

CONIFERS may be multiplied by means of cuttings, layers, and seeds, while the golden or variegated forms of *Taxus*, *Cupressus*, *Thujaopsis*, &c., are generally reproduced by grafting on stocks of their respective green-leaved or normal kinds. Seedlings form the best stocks, but where they are not at command, cuttings may be substituted. The common Larch forms a good stock for the Deodar, as does also *Cedrus atlantica*. The fertilisation of Yews and Cypresses is very interesting. It appears that a drop of clear mucilage is exuded from the orifice at the top of the ovule or young seed of these plants. The pollen grains fall on this mucilage, which retains them, and both mucilage and pollen tubes are absorbed into the interior of the ovule. Vaucher long since pointed out this fact; and his "Histoire Physiologique des Plantes d'Europe" contains much valuable information of peculiar interest to the intelligent propagator and hybridiser. Every one who raises Conifers from either home-grown or imported seeds is well aware of the diversity of colour and habit which the seedling plants

Herbaceous Scion.

assume. This is particularly observable in the Lawson Cypress; but Firs, Wellingtonias, Araucarias, and Piceas show the variation in a scarcely less marked degree; and many of the most beautiful forms of Yews, Firs, Cypresses, and Thujas have been originally either natural variations selected from the seed bed, or sports perpetuated by grafting the variegated branches on a plant of the green or normal form of the species as a stock. Up to the present time, I believe I am right in saying that we have no hybrid Conifers—that is, no garden hybrids raised by artificial fertilisation; for there can be but little doubt that Conifers, being mostly gregarious and furnished with such ample supplies of easily-wafted pollen, are often cross-fertilised or even hybridised in a state of nature; another point in favour of this cross-fertilising process having taken place is that imported seeds produce such a diversity of offspring. There appears to be no good reason why we should not raise hybrid Conifers in our gardens now that we have so many fertile or cone-bearing specimens of the rarer and more beautiful kinds; and I strongly urge those who have the opportunity to make experiments in this direction. By crossing the more beautiful and tender kinds with hardier species, we might obtain a hardier race; and if additional beauty of leafage or habit, so much the better. Again, some rare Conifers produce ample supplies of pollen before they bear fertile cones, and by using this pollen to fertilise older cone-bearing trees belonging to the same or an allied genus, good results might be obtained. Whether, however, success or failure is the result, the careful cross-fertilisation or hybridisation of Conifers is well worth attention from cultivators, as it appears to be as yet an untrodden path in horticulture. The genus *Abies* now includes the Lebanon, Himalayan, and Algerian Cedars. The fully

matured cones should be gathered during the winter season, and exposed either to sun-heat or to the gentle warmth of an oven or kiln—this treatment being requisite in order to readily separate the seeds from the cones. The Firs give out their seeds very easily and quickly—much more readily than the Cluster and Stone Pines, which require the gentle application of heat for several weeks, or even months, ere

The same inserted.

their seeds can be separated from the close-scaled cones. The method of extracting the seeds from Cedar and other Conifer cones by splitting is tedious and often injurious to the seeds. M. Delépine, of Angers, states that the plan he adopts is much simpler and better. About February the cones are buried at a depth of 2 feet underground in sand; they remain there for a month or two, after which the cones

Terminal Bud Grafting.

scale easily without force, and the seeds are then picked out and sown immediately, and, having swelled, they germinate at once. In the case of all Conifers, seeds undoubtedly afford the best mode of re-production whenever they can be obtained; but in the case of rare and new varieties, grafting and cuttings have to be resorted to as auxiliary, and in some cases quicker modes of increasing them. The

cones of Cedars are very resinous when newly gathered, and ought to be left a year before the seeds are separated, much of the resin having during that period passed off by evaporation. The following experiments on the germination of Conifer seeds, made by Mr. J. Alexander, are recorded in the "Transactions of the Scottish Arboricultural Society":—"In the year 1870, twenty cones were gathered from each of ten different trees, whose ages were approximately ascertained by counting the concentric circles in other trees felled beside them. The cones were carefully opened, and all the seeds of the ten different sorts sown in separate beds, the result of which was as follows:—

The seeds of twenty cones from a tree			
300 years old produced	10 plants.	100 years old produced	196 plants.
250	" 13 "	50	" 104 "
200	" 69 "	15	" 46 "
150	" 79 "	10	" 40 "
125	" 106 "		

The same experiment was again tried in 1871 with other trees, when the result was much the same as in 1870. It will thus be seen that seeds gathered from trees between 50 and 125 years produce the greatest number of plants. In a paper on "Gathering the Cones of Resinous Trees," Mr. Ellison maintains by illustrative examples that the premature gathering of the seed tends to weakness in the plants. Foreign seed, he remarks, from the native forests, is invaluable when imported in the shape of fresh-gathered cones, secured from the trees at the end of the Alpine winter; but is not worth having if gathered prematurely. Curiously enough, other seeds have been found to be much improved if left on the plants all winter; and this is notably the case with Stock seed. The latter end of March, if mild, or the beginning of April, is the best time to sow all Conifer seeds; and it is an excellent plan to place the seeds in a bag and soak the bag in water for a day or two, taking care to dry the seeds in the sun before sowing. The rarer sorts are generally sown in pots, pans, or boxes of rich moist earth, and the protection of a pit or frame is given them until they have advanced in growth sufficient to be pricked out in lines in nursery beds. The more common and hardier kinds are, however, sown at once in nursery or seed beds a yard or 4 feet in with. The richer and more friable the soil the better; and the depth at which the drills should be sown must be regulated by the size of the seeds, say from half-an-inch to an inch, which, in the case of the larger and stronger kinds will be amply sufficient. If these seed-beds are sheltered by hedges of Yew, Juniper, Privet, or Beech, so much the better. The seedlings may be lifted about a year after they are sown, or in the April following, and pricked out in lines 6 or 8 inches apart, leaving a space of about an inch between each seedling plant; plants so treated will be found to have made considerably more progress than those left thickly in the seed-beds for two years, an old-fashioned plan still largely practised. As a rule, seedling Conifers should be lifted every year they are in the seed-beds, or until they are either sold or planted out in permanent positions either in woods or pleasure grounds. If seeds are not obtainable the next best mode of propagating Conifers generally is by cuttings made of the side shoots when the sap is active. They should consist of branchlets of last year's growth, say from 4 to 6 inches in length, with a heel of the old wood, which causes them to root better. Retinosporas, Taxus, Thujas, Thujopsis, Wellingtonias, Cedars, Cephalotaxus, Cryptomerias, Dacrydiums, Podocarpus, Cupresses, Libocedrus, Torreya, and many other well-known Conifers, are readily multiplied by cuttings. The usual practice is to insert the cuttings or slips in pots, pans, or boxes of light sandy compost, and to place them in a cool shady frame at the back of a north wall or one having a northern aspect. The more tender species and varieties, however, strike quicker and with more certainty if pricked into pots containing small crocks and about an inch of sandy soil at the top. These, if placed in a genial heat of from 75° to 80°, will emit clusters of white fibrous roots in about a fortnight or three weeks; but they must be carefully hardened and potted off singly, after which they may be placed in a cold frame and finally planted out in the ordinary way. Seed, as I have said, is, however, undoubtedly the best method of propagating all Conifers when it is obtainable; and cuttings are better, as a rule, than grafted specimens, as the latter often throw out lateral leaders instead of terminal or erect ones, and these spoil the symmetry of the trees. Where the central leaders of Conifers do not start away freely, the lateral branches, especially those which grow faster than their neighbours, should be shortened in about October. This throws fresh vigour into the leader and preserves the symmetry of the tree. Many who can bud Roses and graft fruit trees with success, hesitate to operate on Conifers, and this without any apparent reason, except that the plants are a little different in appearance from those with which they have been accustomed to deal. This mode of propagation is, therefore, but rarely resorted to except in nurseries. All Conifers, if not too resinous, may be grafted as easily as a Plum or a Pear. Scions or grafts should be selected from the last summer's growth, and grafted on

stocks of the same or nearly allied species any time during the winter months in gentle heat, the stocks being seedlings or cuttings grown in small pots for the purpose. Terminal grafting, of which the annexed are illustrations, is practised in the spring, taking the scions from the tips of the main branches in a herbaceous state. The scions may be 1½ to 2 inches in length, and should be inserted on the apex of a seedling or rooted cutting of an allied hardier or less valuable species as a stock. This operation is best performed in a heated close case; or, if in open beds, cloches must be used, and the operation must be deferred until the sap commences to move. Nearly all the species and varieties of Picea and Pinus are best propagated by means of grafts when seeds are not to be had. The Silver Fir makes an excellent stock for all the finer varieties. The numerous species of Pinus grow well on stocks of the different types to which they bear most resemblance. For example, such species and varieties as look like the common Scotch Pine grow well on that species as a stock; while *P. monticola* or *P. Laubertiana*, and their allies, do better on *P. excelsa* or on the Weymouth Pine. *Cupressus Lawsoniana*, which is readily propagated from seed, and is of clean habit, forms an excellent stock for the dwarf, dense, or variegated form of Lawson Cypress. Nearly all the Fir tribe take kindly to the common Spruce as a stock; while *Biotas* and *Thujas*, as a rule, succeed best on the Chinese *Arbor-vitæ*. In the "Révue Horticole," 1867, M. Briot states that *Libocedrus tetragona* succeeds as a scion on *Saxe-Gothæa*; and its habit, in consequence becomes

Fork Grafting.

changed into a wide-spreading head instead of forming a narrow cylindrical column. *Chamaecyparis obtusa pygmaea*, grafted on *C. Boursierii*, grows erect; while if worked on *Biota* or *Thuja*, or if propagated from cuttings, the plant spreads horizontally on the ground. *Pseudo-Larix Kempteri* is best propagated by grafting scions on its own root, moderately thick pieces well furnished with fibres giving the best results. This mode might be used with advantage in the case of other rare Conifers which are difficult to propagate by cutting. F. W. B., in the "Gardener."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Berry-bearing Aucubas.—In order to induce the Aucuba to fruit successfully, graft or bud the centre branch of the female plant with the male kind. I budded mine. I have been long expecting to see combined male and female plants advertised; and have wondered that some of our nurserymen had not made this combination a feature in their shrub catalogues.—JOHN DENNY.

Chinese Primrose Princess Louise.—The blooms of this variety are of such a massive character as to render them quite distinct amongst a large collection in bloom here at present. Not the least of the many good qualities belonging to *Primula* is that their beauty is greatly enhanced when seen under strong artificial light—a great desideratum in plants for winter decoration.—JAMES GROOM.

Wellingtonia gigantea.—A very fine specimen of this tree is growing in the nursery here in a thin, poor soil on the Greensand. It is a complete cone of verdure from base to top. Its stem is 42 feet in height, and its girth, at 1 foot from the ground, is 6 feet 8 inches; at 5 feet up, it measures 5 feet. The following were its dimensions in 1868:—Height, 25 feet; at 1 foot above the ground, 4 feet, and at 5 feet up, 2 feet 6 inches. From enquiries which I have made about the age of this tree, I find that it is nineteen or twenty years old.—GEORGE BERRY, Longleat.

FENCES AND SCREENS IN PARKS AND GARDENS.

A more natural style of landscape gardening than once prevailed has, to a very great extent, abolished from ornamental grounds fences of the wall-and-hedge description, a fact which cannot be regretted, for fences are incompatible with that freedom of aspect which should always be aimed at in the disposition of ornamental grounds, either extensive or otherwise. In parks where cattle are admitted some kind of barrier is necessary to protect the plantations, but there are ways of accomplishing this now without resorting to the plain stone fence, or hedge, or expensive ha-ha—all of which are objectionable. Nothing more than the edge of the wood should denote the boundary line. If a fence is necessary a wire or iron one will, perhaps, be least expensive in the end, and it may be placed so as to be invisible to the ordinary observer. It is not unnecessary to state this much, for the very object of wire fences is frequently lost sight of in their erection. Only the other day we saw an ornamental plantation in the course of being railed off by a wire fence, which was rendered hideous by cumbersome sawn wooden posts placed every 15 or 20 feet apart. This is a common way of putting up such fences when the work is entrusted to those who know nothing whatever of their object. In other cases, where it is needful to fence park plantations temporarily, a strong but light fence is used, which does not offend the eye. In some very extensive domains we have seen, where the parks are tenanted summer and winter by highland cattle, not a fence is visible for miles from the mansion, but the fences are there nevertheless, miles and miles of them, and they consist of a few strands only of wire rope stretched upon rustic posts placed pretty widely apart, close to, and near the drives and avenues, quite within the margin of the plantation, so that they cannot be seen except they are looked for, and they follow every winding of the wood. Wherever the presence of fences is objectionable this plan will commend itself. It is only necessary to have wires strong enough, as cattle scratch themselves upon them and strain them. Where sheep graze, the wires must be closer at the bottom than the top. Such fences might be made to supersede sunk stone fences, which often enclose pleasure grounds and form boundary lines to plantations skirting the park; but as these are common, and cannot at all times be hid from the sight, the best plan is to plant the common Ivy on the top and let it grow down, which it will do readily and quite hide the stones. The Ivy can seldom be planted at the bottom of the wall, as a watercourse is generally formed there. In pleasure grounds, fences of any kind are hardly admissible at all, except as barriers or screens. For the first the wire fence of the lightest substantial description is the best, and for the second nothing surpasses hedges of Holly or Ivy—the latter supported, of course—and next to these comes the Laurel, the Yew, Bay, evergreen Oak, and Furze, all evergreen. The Holly hedge is the best of all, as well as the most ornamental, but it takes a long time to grow, and not a little keeping; nevertheless, it is worth all the trouble where a good fence is required. Where high buildings or other objects have to be hidden the trees should be planted thickly, and neither clipped nor topped. If they have light and air they will furnish densely enough to their base and form a complete screen. Some twenty years ago a hedge of this kind was planted, and now the trees are about 40 feet high, and form a perfect wall of great thickness. The Ivy hedge is soonest formed, and makes an impenetrable screen. Planted carefully in ordinary good soil, and supported by some substantial wooden structure of Larch poles, spars, or other materials, it will make a screen in a year or two. Laurels make a good hedge at first, but eventually get thin and unsightly at the bottom. The Yew has the same fault; still we have seen Yew hedges of considerable age, tolerably well-furnished to the bottom, and 20 feet through, clipped square at the top and sides. For some situations nothing is better or more ornamental than a fence of Furze. In the Isle of Man the excellent roads are a feature, and are only equalled by the hedges of Furze with which they are lined. The Furze is planted on low turf walls, into which the roots penetrate, binding it effectually, and the branches form a lofty and formidable barrier, that a man on horseback cannot see over, much less get through. Fences of Furze will grow where most other hedge plants will fail, and they will bear cutting

and clipping if they are not wanted too lofty or straggling. The turf walls are first made about 4 feet high, with a broad base, and the Furze may be either sown or planted. Of deciduous hedges admissible in ornamental grounds, we need only mention the Lime, Lilac, Barberry, and Sweet Briar. The Lime, when kept low and clipped, forms a good screen, and is frequently used as such between villa gardens. Very good examples of Lime hedges are to be seen in the suburbs of London. The trees are usually planted against the boundary wall of the garden, and are kept below 20 feet in height by periodical clipping, which causes them to furnish laterally, and by trimming the sides also with the shears, a good square hedge some feet in thickness is formed. The trees should be planted of a good height at first. The Lilac makes a highly ornamental screen, but if it is wanted to flower, it should not be cut nor trimmed too closely. If it is not shaded by other trees, it will furnish freely enough to the bottom. Sweet Briar and Roses of the climbing section make a charming hedge, and the pretty effect may be heightened by introducing Clematises here and there. In forming such a hedge it is necessary to provide a rail or twot first in order to support the plants. Afterwards they must not be trimmed too closely, but only kept from straggling, and occasional young strong shoots should be laid in at the bottom to keep the hedge filled. In many gardens hedges are found very serviceable in protecting tender plants from cutting winds. Nurserymen trust to them largely, and some nurseries are a complete network of Beech, Yew, or Holly hedges. The Beech, as it grows quickly and retains its dead leaves on the branches all the winter, is the best for the purpose. The best arrangement of hedges for protection that we ever saw in a private garden consisted of a series of hedges about 5 feet high, running north and south, about 20 feet apart, with a good high Holly hedge on the north side as a base, and all open to the south. In these spaces many tender plants were hardened off in spring, and in summer they were filled with greenhouse plants that then required to be out of doors. They formed good nursery beds for various kinds of vegetables also; and fruit trees in pots were much safer between the hedges than on the open border.—“Field.”

The Plane Trees in Piccadilly.—I have travelled Piccadilly to and fro every day for many years past, but, until quite recently, never noticed anything peculiar in the growth of the young Plane trees, planted in parallel lines just inside the Green Park. The peculiarity to which I allude consists in the stems of all the young plants inclining several degrees towards the east. Those in the row on the left hand side of the north path going west are more conspicuous in their inclinations than the others. Those planted between the Elms on the right hand side and near the iron rail fence are less so; but even there the inclination is quite obvious. The old Planes in the park and those on the footpath in Piccadilly seem to have developed themselves in the normal way, rendering the growth of the young ones still more singular. While writing, perhaps you will allow me to say that I trust soon to see the young Planes between the Elms removed as they are spoiling each other.—*STRIGLIA*.

New Golden-leaved Poplar (*Populus canadensis aurea*).—Our list of wholly golden-leaved trees is a short one; indeed I only know of three prior to the one now under notice, viz., *Quercus Robur concordia*, *Catalpa syringefolia aurea* (which Mr. Rogers used last season at Battersea with such excellent effect in connection with Jackman's purple-flowered Clematis), and Mr. Richard Smith's Golden Laburnum, a really vigorous and effective golden sport from the common one. M. Charles Van Geert's Golden-leaved Poplar, judging from a coloured plate of it which I have seen, is a valuable sport from the Canadian Poplar. It is reported to have been produced spontaneously by a branch of the green-leaved type, on which it maintained its golden character for five years. Its leaves are described as being “quite as large as those of the common Poplar, and the yellow hue, instead of looking sickly, has a warm and vigorous tint. The better nourished the tree is, and the more it is exposed to the sun, the more vivid is the golden hue. The stalks and the bark of the shoots become then dark red, which adds greatly to the beauty of its colouring.” This new variety, if at all like the drawing, will be of the utmost value for grouping along with purple-leaved Beech and other ornamental trees; and young grafted plants of it ought, I think, to be valuable in summer garden arrangements and in subtropical gardens.—B.

PLATE III.

TEA ROSE, DUCHESS OF EDINBURGH.

It is many years since the veteran Rosarian, Mr. Rivers, of Sawbridgeworth, pointed to the Tea Rose (*Rosa indica odorata*) as that which would dispute the palm of public favour with the Hybrid Perpetuals. With softness and delicacy of colouring, combined, in the best varieties, with a beautiful form, especially in the unexpanded bud, the Tea Roses have for years been increasing in favour; but the drawbacks attending their culture in the open air, and the want of bright colours, have long been against them. The Tea-scented Roses, it is well known, are, with two or three exceptions, less hardy than the Hybrid Perpetuals; and to grow them out of doors in perfection, in Britain, requires some care and nursing on the part of the cultivator. In France, the Tea Roses do not seed nearly so freely as other families of Roses, and the seedling plants raised have shown much monotony of colour, and this generally of a light tint. Few varieties of merit, and distinct in colour, have hitherto been added to existing established kinds, compared with the rapidly increasing numbers of Hybrid Perpetuals. At length, however, a "break" has been made, and a Tea Rose of a rich brilliant colour has been obtained, and is now in cultivation. This distinct Rose, of which the annexed plate is a faithful representation, has been distributed by the Messrs. Veitch, of Chelsea. The Rev. Canon Hole says of it, "I admire the Rose, not only for its originality, novelty, and distinctness, as the only Tea Rose of its colour; but because I think it will prove a welcome acquisition as a plant in the conservatory, and as a cut flower in the bouquet." In habit, it is rather robust, forming a compact bushy plant, with smooth stems, having large thorns sparingly scattered over the branches; leaves, medium-sized, smooth, deep green; flowers, brilliant crimson, globular and abundant. It was raised in the south of France.

I.

THE AMATEUR'S GARDEN.

BY THOMAS BAINES.

Plant and Fruit Houses, Pits, &c.—Both in the erection and arrangement of these amateurs often commit great mistakes. Even when they are of the least pretentious description, it frequently happens that they are so placed that it is impossible to work them satisfactorily. In the first place, however well a house may be constructed, as to convenience and general utility, if placed in a position where it cannot receive the fullest amount of light, no matter from what cause, the results can never be satisfactory. In considering this subject, it is necessary to bear in mind that in selecting a site for plant or fruit houses, it is not alone requisite to have them where there are neither other buildings nor trees that intercept light by standing at the sunny side of the houses to be erected, but also to place them far enough away from anything of this character that will obstruct light, although on the north or unshaded side. In the cultivation of such flowering plants and fruits as require the protection of glass we must never forget that these, almost without exception, receive in their native countries more light than we in England can possibly give them, even in the best constructed houses, placed in the most favourable positions; the want of attention to this fact is too often the cause of continuance after disappointment. Take, for instance, the small conservatories or plant-houses attached to amateur's dwellings, instead of the well-being of the plants to be grown in them being made the first matter of importance, it is often lost sight of altogether, until it is found that little or nothing will grow in them. Such structures are frequently placed in a north or east corner, flanked on two sides by the walls of the building which overshadows them, the unfailling result of which is that the plants produce very little flower, and become in a short time mere shadows of what they ought to be. When a plant-house is built in such a situation it should be devoted to the growth of Ferns and similar shade-loving subjects, which thrive under such conditions, and, in the selection of the different species of Ferns for cultivation in houses so placed, amateurs will find that it is much the best plan to grow none but those which require a greenhouse temperature, as these will not only succeed better than stove species where there is a deficiency of light, but they need much less attention in all ways. Insects do not increase so fast upon them; and, where means exist of preparing flowering plants in other houses, some of these, whilst in bloom, might be introduced among them.

In houses, situated as in the case just alluded to, it will be found much more satisfactory to thus confine the cultivation to such plants as will thrive in them than to attempt to grow such as cannot be induced to succeed. Another mistake often committed is to erect plant-houses against existing buildings that are very much higher than they are; for, even when placed at the south side of them, so much light is intercepted, that the plants become drawn by a continual struggle to get their heads to the glass. In situations of this kind Vines will do much better than flowering plants, but even they are better farther away from influences inseparable from such a position.

Span-roofed Houses Best.—For plants of any description there is no form of house equal to a span-roofed one, placed, if possible, with the ends standing north and south. In this case the inmates have little disposition to become one-sided or drawn; on the contrary, they maintain their natural character, and possess a robustness of health only attainable when grown under the influence of a maximum amount of light. Further, I may add, in reference to this form of house, that there is nothing equal to it, either as regards the health of the plants to be grown therein, the strength of the structure, or the cost of construction. Those elevations known as lantern lights, or raised ridges, extending, more or less, down each side, are in every way highly objectionable. A roof thus formed is, from its shape, inevitably weaker than a plain span, it is much more costly, the additional amount of material, whether wood or iron, excludes light, and much more fuel is required to keep up the necessary temperature than otherwise would be the case. Should the house be required for stove plants or even for occupants simply needing the exclusion of frost, the heat, immediately it is given off by the pipes, rushes straight up into this elevated portion of the roof, and quickly makes its escape. Such a form of roof as this is only suitable for a large conservatory attached to a mansion where something of the kind is demanded in order that it may harmonise with the design of the building with which it is associated and to which it is subservient. Under no additions is it advisable to build lean-to-houses, nor even against existing garden walls that are no higher than the top of the roof lights, except for Vines, Peaches, or Cucumbers, that, from their nature need root training and every ray of light that passes through the glass.

Heating.—As regards this amateur's structures are often deficient. The boilers, pipes, or flues are frequently so placed as to be uncertain and inefficient. The main objection to flues is their liability to crack, and allow smoke and gases to escape among the plants, and they also require cleaning out yearly. Where there are several houses, too, they render it necessary to have more fires than one, otherwise the working of them is simple enough, and the first cost is less than that of heating by hot water; taking, however, everything into account the latter method is best. The forms of boilers now before the public—many of them mere "differences without distinctions," yet each introduced as the best—are a complete puzzle to many, and those who are inexperienced in such matters are often induced to adopt such as are wholly unfit for their purposes. There is, however, one particular description of boiler that I would especially warn amateurs against, and that is those small kinds that are warranted "to heat with the least conceivable amount of fuel," and which are so constructed that they will not hold or can be set so as to hold enough material to keep afloat for more than a few hours without a fresh supply. These are the most inconvenient contrivances ever invented. They are uncertain in their action, and require constant attention to ensure the exclusion of frost in severe weather. The best and most simple boilers that amateurs can employ, taking all things into consideration, are any of the improved "saddles" with a flue or flues running through them, and through which the heat traverses instead of rushing direct from the furnace up the chimney; these, when well set a little below the pipes, with room enough to hold a good body of fuel, will always be found to work satisfactorily. Another consideration of especial importance where several houses are to be warmed from one boiler, or where there is a likelihood that at any time more may be erected, is to place the boiler in the centre of its work, the houses or pits being right and left of it; where sufficient forethought has not been exercised in this matter, it frequently happens that serious difficulties arise. For similar reasons, the structure that will need the most heat should always be next the boiler, for, if this is not the case, a waste of heat must necessarily occur. In all cases none but the best valves should be used, so as to completely shut off heat when it is not required in any particular house. Another essential point is having enough piping in each house to keep up the requisite temperature without any strain upon the boiler; for, whenever it happens that the fire has to be hard driven, it is necessarily at a sacrifice of fuel. Unless under unavoidable circumstances, the pipes ought to rise, slightly and continuously, all the way from the boiler to the farthest point to which they extend;

and be so placed that they can be easily got at, in order to repair any leakage that may occur. Yet it often happens that considerable lengths of piping are laid underground, where they are inaccessible without a good deal of excavation, heating the earth for no purpose before they enter the house; whereas had the boiler been placed in the best position, both waste and inconvenience might have been avoided. Few of the gas-stoves, or similar contrivances, employed for heating small greenhouses, work long with any degree of satisfaction—a remark which also applies to such structures as are attached to dwellings, and are warmed from kitchen boilers or fires, that are used for another purpose besides that of warming the glass-houses in question, there either being too much or too little heat. Where, perhaps, the heating in this way is continually under the control of an amateur, who is enthusiastic in his attention to the flowers which he cultivates, success may be attained; but, where this work has to be left to others, the result generally is that the heat is off some severe frosty night; and the fruits of much time and care are ruthlessly destroyed. It is always better to have the heating apparatus for such places separate from anything else; this, even on the score of saving of fuel, will, in the long run, be found the most economical.

Conservatories.

In order to keep up a gay appearance in these it will be necessary to introduce into the forcing-houses or pits a constant succession of plants that, when in bloom, will stand in a comparatively cool temperature. Much harm is frequently done to creepers and other permanent occupants of conservatories by introducing stove plants and raising the temperature to suit their requirements. Wherever this is done it has injurious results, as the plants are kept constantly growing all through the winter, a time when they should be enjoying a season of rest. A temperature, ranging from 45° to 55°, will be ample just now for any conservatory, and will be found to keep plants much longer in bloom than if a greater heat is maintained. Plants in hanging-baskets soon become exhausted on account of the small body of soil on which they have to feed. The present is a favourable time for removing a portion of this and replacing it with good rich fibrous loam, which should then be thickly covered with Moss to prevent the sun and air playing too freely on it and robbing it of its moisture. For suspended baskets there is, perhaps, no plant so effective as Rollison's Unique Pelargonium, which may easily be had depending from 3 to 5 feet, laden with bloom; and, when associated with a few plants of the old Ivy-leaf, or its more beautiful variegated form, L'Eleganté, it is perfection as regards grace and beauty.

Forcing Houses.

In these a temperature of from 55° to 65° will be quite sufficient for all purposes, and will suit the generality of plants better than a higher one. It will invariably be found to be more satisfactory to start early and force slowly than to urge plants rapidly on to the blooming period, as, when that is done, flowers are sure to be produced which have thin flimsy petals, and which, consequently, are short-lived. To assist them to stand in a cut state, or when removed to decorate the conservatory, they should, if convenience exists for so doing, be moved to a lower temperature just before the buds expand, and be kept well up to the light. This will not only greatly assist them as regards power of endurance, but will impart a brighter and more natural colour to them. Much needless forcing may be saved by selecting plants that naturally flower early, such as many of the Rhododendrons, *Azalea amona*, *Deutzia gracilis*, the double *Frunes*, *Lilacs*, and plants of that class. Among *Rhododendrons*, *Altacereuse*, *Jacksonii*, *caucasicum*, *c. pictum*, *Cunningham's White*, and *Brayanum* are the most valuable. All of these may be had in bloom with little forcing, while, for size and beauty of flower, they rival most of the later varieties. *Brayanum*, especially, is one of the grandest of *Rhododendrons*, having flowers of enormous size, fine in colour, and of the most perfect form. Such subjects as *Lilacs*, *Weigelas*, hardy *Azaleas*, *Sweet Briar*, &c., may be placed for a few weeks in almost any position where they can have the advantage of a little heat to bring them quietly on. Keep them constantly moist by syringing them with tepid water, and remove them to a light position as soon as their buds become well advanced. The beautifully variegated *Acer Negundo variegatum* makes a charming conservatory plant when forced, so as to get it early into leaf, as under such circumstances the variegation is much more pure and delicate than it otherwise would be. By introducing a few of these among bright coloured flowers or deep green foliage, such as that of the *Camellia*, they have a pleasing effect. Poinsettias going out of bloom should be placed in a dry, airy situation, where the temperature does not fall below 50°. Keep their tops entire, and give but little water, so as to induce the wood to become firm and fit for propagating purposes when wanted. Early flowering *Pelargoniums*, such

as *Alma*, *Solomon*, *Crimson King*, *Gauntlet*, *album multiflorum*, and others of that class, should be placed on shelves close to the light to keep them from "drawing." A moderately dry atmosphere and a temperature ranging from 50° to 60° will just suit them. All the above will come in early in March, and will continue in flower for at least three months.—J. SHEPPARD.

Stove Ferns.

Preparations should now be made for potting such of these as require that attention. If the soil for this purpose is not already under cover, it should be immediately placed there, as it should not, under any circumstances, be used in a wet, cold state. Fibry peat and good yellow loam will be the only soils required for potting purposes, and the proportions in which these are used will greatly depend on the plants to be potted. *Gleichenias*, *Gymnogrammas*, *Nothochloenas*, and other tender kinds will require at least two-thirds peat, while other strong-growing varieties will be benefited by having loam in that proportion. Therefore, in breaking up and preparing the soil, it will be best to keep both separate, so that they can be mixed up when wanted in the proportions necessary to suit the requirements of the different plants to be operated upon. Where unsightly bare walls exist in Fern or other plant-houses, they may be quickly and beautifully clothed by planting in pockets attached to them, Ferns or trailing plants, such as *Pothos argyraea*, *Cyanotis vittata*, *Panicum*, &c. The pockets may be formed of cinkers, dipped in liquid cement a few times to give them increased strength and hide their objectionable colour, after which they can be attached to the walls by means of stiffer cement. Any handy bricklayer or garden labourer will be able to accomplish this in a satisfactory manner, and thus unsightly bare places under shelves or elsewhere may be turned to profitable account. Ferns grown in this way are much more effective and natural-looking than when grown in pots, and as they are invariably stronger, more fronds can be spared for cutting, in order to dress flower-vases, a purpose for which they are in great request in most places. Many of the most elegant drooping varieties, such as several of the *Goniophlebiums*, *Davallias*, *Aspleniums*, &c., only show off their beauty to advantage when planted out in elevated positions, such as may be prepared in the above manner, or when placed high on pedestals, or in tall vases. Plenty of ripe seed of most kinds may now be obtained, and where it is desirable to raise seedlings, no time should be lost in collecting and sowing it. In preparing pots for this purpose, they should be drained to at least a third of their depth with broken shreds or soft porous bricks, over which should be placed a layer of Moss. The pots should then be filled to within half-an-inch or so of their tops with some good fibrous yellow loam. This should be rammed firmly down, making the surface quite level and smooth, and on this sow the seed. After this is done, pieces of the frond may either be laid on it or the seed brushed out, so as to be equally distributed over the soil. Pieces of glass should then be laid on the top of the pot, to exclude air and retain moisture. The pots should then be placed in shallow pans of water, which must never be allowed to become dry, though an inch or so will be sufficient. Until the seeds vegetate, a light warm place must be chosen for them out of the reach of sunshine.—S. W. P.

Roses.

All *Roses*, intended to be planted this season, should now be planted while the weather is favourable. Plant also stocks and cuttings in beds. Renew stakes and poles where necessary, and commence to prune and train all climbing *Roses*. In doing this, it is advisable to remove all old ties and shreds, which are apt to harbour insects. Where standard *Roses* are planted in damp soils they will probably be found to be covered with Moss. In that case, mix up a painful of water, soft soap, soot, and a little clay, the last to give the whole the consistency of paint, and paint over the stems and other parts affected with the mixture. This will kill the Moss and give the *Roses* a clean appearance. *Tea Roses*, covered up, should be opened during this damp weather and examined, in order to see that they are not suffering from confinement. Damp, in fact, does as much harm to *Tea Roses* as frost. *Roses* intended for cordons should be trained in that way, as opportunity offers, so as to get them to break evenly. Continue to manure and dig between *Roses* and *Rose beds*.—H. G.

Indoor Fruit Department.

Vines.—*Vines* started in the latter end of October and beginning of November will now be showing clusters of fruit; therefore thin them at once to the requisite number required, avoiding, in all cases, heavy cropping. Attend strictly to finger and thumb pinching; for, allowing shoots to grow so strongly as to necessitate the use of the knife is wrong. Tie in carefully as growth proceeds, pinching out all laterals, but allowing three or four extra leaves on the side shoots. Whether the shoots are stopped at the bunch, or

two, three, or four joints beyond it is unimportant, so long as sufficient foliage is left to aid vigorous growth. Thinning may take place immediately the bunches can be handled. Avoid a too free use of the syringe and water-pot at this dull season; allow a little front air at night, when there is no frost. The top ventilators in our early house have never been moved, while front air has been kept on, with the exception of a few nights, since October. From 60° to 65° will be found to be a high enough temperature at night, letting it rise considerably higher by day. True Vines in late houses, immediately the foliage is off, retaining only shoots on which there are bunches; keep up a good circulation of warm air in houses in which Grapes are still hanging in order to prevent decay. Look over them often, and remove at once all bad berries. Give air on all favourable occasions, but keep the ventilators shut on wet and thick misty weather; prevent the temperature falling below 40°. If such houses are required for plants or need painting at this season, the Grapes may be cut and placed in bottles of water in the usual way. Place a few pieces of charcoal in each bottle, and fill them up with rain water; then suspend them in a suitable place in the fruit room, or in a Vinery that has been cleaned, kept well aired, and shaded during bright sunshine by a piece of frigidomo. Last year, Grapes were kept good here until the last Vinery was started, when they were thought by many practical men to be better in flavour than when kept in a fruit-room.

Pines.—Where early fruit is in demand, a selection of the most forward Queens should be brought together in accordance with the space at command. Remove all the short leaves round the base of the plants, and have all inert soil taken from the surface and replaced by a mixture of bone-meal and fresh turf, ramming it down tightly with a blunt-ended piece of wood. Take particular notice of the state of the balls as to moisture; have all the plants plunged in a tan bed ranging from 80° to 90°. Water such plants as may require that attention with guano-water of the same temperature as that of the plunging bed. Avoid a high atmospheric temperature at night; from 65° to 70° will be found sufficient during these dark nights. Let all forcing be done by day, husbanding the sun's rays when available. Damp all floor and wall surfaces, but avoid syringing overhead.—J. HUNTER, *Lambton Castle*.

Peaches and Nectarines.—There is often much anxiety during this month, when Peaches are setting, especially where there is only one house to depend on for the early crop; Peach trees, which have been cropped for years, are often found to have become weakened in growth, and the fruit buds, which are thickly studded over the shoots, single, instead of being double, with a wood-bud between them. It is in such cases that the buds are liable to drop; and, when they are superabundant, it is not always in their favour. It has been a practice of ours, for years, to thin the buds, so that those best placed may have room to fully expand, and not tax the strength of the trees more than is desirable. Shoots, which have no young leader, seldom ever swell off any fruit; and it is best to cut them back to a plump bud, which is likely to form a good bearing shoot for next year. Where trees happen to cast their crop, they should be well cut in, and as many shoots led up as will take the place of the old wood cut out. If the borders are well renewed with rich soil, as before advised, and a good soaking of manure-water given (guano and soot-water, given clear, is excellent), the trees may be invigorated, and will bear well for many years; but where the flowers, or newly-set fruit drop from growth which has not been ripened, and that which is gross and green, stimulants would do more harm than good. The roots would then require lifting at the proper season. It may be mentioned—for the sake of beginners—that some kinds of Peaches and Nectarines do not force well. Caution, as regards fire-heat, is always of much importance, when early forcing is going on during damp and dull weather; 50° to 55° at night should be the maximum temperature till the fruit shows that it is swelling, and 60° should only be reached when the weather is mild and sun-heat husbanded. Air left on at the top of the structure, sufficient to allow stagnant moisture to escape and cause a gentle circulation of air, is always beneficial; but during severe weather this must be done judiciously. Thin out the shoots, and any leaders which are growing too vigorously at the expense of the others should be stopped. In the case of young trees which have started into full growth, all the strong-growing wood may be stopped, which will cause plenty of wood to start and form a tree of even growth. The side shoots are always preferable, and all disbudding should be done piece-meal, so that the least possible check may be given. The aid of a camel's-hair brush is often brought into use for circulating the pollen. It may be drawn frequently over the flowers, between eleven o'clock and two. Pruning, washing, and dressing the trees in succession-houses should have attention as early as possible, and where scale has been on the wood, two washings with warm soapy water or Gishurst compound is not too much. When once this pest is established in Peach-houses

there is much difficulty in getting rid of it. Figs which are in pots and plunged in bottom-heat may now require liberal supplies of water, and if the pots are full of roots, manure-water, such as guano mixed with sheep's manure, may be used to colour the liquid; but putrid manure-water used under glass is productive of much evil. Any shoots taking the lead should be stopped in time, and as Figs make large foliage, they are easily overcrowded; 50° to 55° at night should not be exceeded, and if fruits set very thickly they should be thinned before they thin themselves. Leave the earliest and largest of the fruit; stop established trees at every fourth leaf; and press the points instead of breaking them, which will prevent bleeding. If scale appears, prevent it from becoming established by washing the young wood and leaves with warm water.

Cherries.—If Cherries are wanted in May, now is a good time to commence forcing them. But they must have little more than protection at first, and 40° to 45° should not be exceeded, except when the temperature rises naturally, when, of course, it cannot be prevented. Syringing them with tepid water and giving fresh air at all times are important matters where Cherries are forced. An even temperature must, as far as possible, be maintained, and shading must be avoided. If the trees have been prepared in the manner recommended for Figs and the pots are clean, properly drained, and top-dressed, a crop of Cherries is easily secured. Failures arise from attempting to force the trees too rapidly. A fine display of fruit-buds which open well is no guarantee of success, and in most positions on open walls we often find favourable appearances of this kind to be succeeded by failure.

Orchard-houses.—These structures are most valuable when they are managed so that a long succession of crops may be supplied by having the earliest and latest fruits under cultivation; but where there are no means of keeping out severe frost, it is useless to attempt anything like growing early fruit in orchard-houses. Where trees were replanted or placed in fresh pots they will require nothing at present; but where the crops have to depend in a great measure on nourishment furnished during the fruiting season, all that is useless in the shape of old surface dressings and inert soil should be removed, and a dressing of good loam, well mixed with a portion of bone-meal and rotten manure, should be laid over the roots. If the house is not in use for protecting vegetables and storing plants the fruit trees may be put in their places, and sufficient water given to prevent the soil from becoming very dry. All necessary pruning, and washing the trees should be finished this month.—M. TEMPLE.

Forced Vegetables.

Cucumbers may be benefited by an increase of temperature when the weather is bright, but, where pipes or flues have to be made excessively hot to keep up the temperature, it is better to allow the thermometer to fall, as being by far the least evil of the two. At night 70° is a good temperature, but winter Cucumbers are often obtained where a temperature of 60° could not be maintained during severe weather. Where structures will allow a covering of mats or other material to be placed over them at night, much help may be given to keep an even temperature and save fuel. Surfacing with turfy loam must be attended to, as the roots come through the soil. Except when there are many roots in a limited space, and cropping has been heavy, stimulants are seldom necessary at this season. A healthy, moist atmosphere, free from impurities arising from the heating apparatus, &c., and a steady bottom-heat of not more than 85° are essential, while the days are short and dull. Seeds may now be sown for spring crops. If manure is employed for heating, it should have been well sweetened by turning, and the lights allowed to remain open a quarter of an inch at the top to allow the steam to escape; use small pots, with single seeds sown in the centre of each, light turfy loam, and leave space so that an earthing may be given to the stems of the young seedlings, as they root freely upwards, and when a second shift is given or the plants are placed in the beds permanently, abundance of feeders will be ready to run into the fresh soil. Little can be said to supplement the directions previously given with regard to other vegetables now being forced. French Beans may be brought forward in quantity, keeping up successions by sowing at least every three weeks. Careful watering and plenty of light are of much importance in cold and changeable weather, and a little air should be given daily when the weather will permit. Give heat, as for Cucumbers, to Tomatoes swelling fruit; and the roots confined in pots may be helped by guano-water. Allow the flowers to be freely exposed to light, so that they may set freely; reduce the bunches to three fruits each, if they are wanted large; and allow none of the plants to become crowded, or to shade each other. A temperature of 60° to 70° will suit for the present, and as low as 50° on mornings when the weather is very severe will do no harm. Seakale, Rhubarb, Chicory, &c., should be brought forward by having several successions going on

at no time, so that hasty forcing should not be had recourse to. Mushrooms are generally plentiful at this season; but successive beds should be coming forward to yield supplies when earlier ones cease bearing. When beds are bearing very freely, a very low temperature may be allowed. Last winter, we had excellent crops gathered from beds where the temperature of the house was often at 40°. Potatoes, Carrots, and Radishes, may have abundance of air, and be as near the glass as possible. Avoid exposing the crops to frosty winds, but air should be given whenever the weather will allow it being admitted. Succession beds of the two latter may be sown. Potatoes may be put on turves, Moss, or in pots, to sprout preparatory to planting. They must not be hurried, as small useless tubers only would be the result. Get a few potsful of Herbs, such as Mint, Tarragon, and Fennel, or any sorts required, placed in gentle warmth. Give a soaking of water at 95°, to start the roots. Bottom-heat and a moderate top-heat will give strong produce; but they grow freely in almost any position.—M. TEMPLE, *Impey Hall*.

Kitchen Garden.

As the sowing season is fast approaching, lose no time in procuring a supply of seeds, in order that they may be at hand when wanted. Good seeds, rather than cheap ones, should be sought after, as a good seed-bed is invariably the precursor of a good crop. As to the variety of each kind of vegetable best worthy of culture, amongst the many novelties and synonyms of recent years it is somewhat difficult to decide. I shall, therefore, not attempt to give any precise list, but, as occasion requires, name those that, in my own experience, have proved the most valuable. Every week, now, will bring its own work, and, in order to keep pace with the season, let all arrears in the way of trenching, digging, and manuring have attention at once; not necessarily rich, but deep culture is essentially required for most kinds of vegetables, deep culture enabling them to withstand drought better than all the manure that can be used. Trenching, therefore, should not be done grudgingly, as the little extra labour now required in performing it will be repaid with interest during the coming summer—first, by little or no watering being needed; secondly, by less weeding and hoeing being necessary; and, lastly, by the growth of more succulent and sweeter vegetables. Plots of Winter Spinach that have been picked from for some time, should, on our dry soil it was never better. The round-seeded kind may now be sown between rows of Peas, and will come off before it is of any detriment to that crop. Earth up and stake Peas; a few Spruce Fir or Laurel branches intermixed with the ordinary stalks form good protectors from the weather. Another sowing of first and second early kinds may now be made, such as William the First, Advancer, and Best of All. The following may also now be sown on a warm sheltered border, viz., Early Horn Carrot, in drills 9 inches apart; Early Frame Radish, in the same way; Lettuce, Cauliflower, Cabbage, and Savoys, in drills 6 inches apart. In fine weather stir the soil between rows of Cabbages, fill up from the seed-bed all gaps, and make fresh plantations at any time when ground is at liberty for that purpose. Green crops are always acceptable; and, even should they not be required, they may be dug in as manure, a purpose for which they are of considerable value. Protect with litter, leaves, or Bracken, the stools of Globe Artichokes; and, as soon as all danger from severe frost is over, lift and divide them, selecting the strongest crowns for re-planting in light rich soil. This mode of culture ensures, during the season, a never-failing supply of large plump heads. New plantations of Horseradish may now at any time be made. The ground should be deeply trenched, and a good layer of manure put at the bottom of each trench; for planting, select straight stems from 6 to 9 inches long, and plant them deeply with a dibber, in rows 2 feet apart, and a foot asunder in the row. At this season lift all Brocoli as it becomes ready for use, there being no certainty as to what the weather may be. Continue, also, to protect Lettuce and Endive; the latter should be tied and lifted when dry, and put in a Mushroom-house or in some other dark dry room or shed, to blanch. Plant a few Chicory roots occasionally, according to the demand, in sand or dry soil, in similar places, and keep up a supply of Mustard and Cress by frequent sowings in shallow boxes. Mint and Tarragon, if in request, may be potted and grown in any spare corner of the forcing houses. Prepare manure for the forcing of further supplies of Asparagus, Seakale, and Rhubarb; the former is best lifted and grown in pits or frames, but the two latter should be covered with pots, and forced where they grow. A hot-bed should also now be prepared for raising seeds of Capsicum, Cucumber, Celery, Cauliflower, Lettuce, Tomato, &c., after which it may be utilised for a crop of Early Horn Carrots or Six Week Turnips.—W. WILDSMITH.

THE FRUIT GARDEN.

THE CHERRY GARDEN.

THE Cherry, like most of our fruits, came originally from Asia, and, like all trees from warm eastern countries, produces its blossoms early in the year, a circumstance which makes them liable to be destroyed by spring frosts. Any good ordinary soil suits Cherries, but light sandy loams answer best for them. When worked, however, upon the Mahaleb stock, they thrive in any kind of soil, and even luxuriate in strong clays; in fact, anyone with a spare corner, no matter what the soil is, would find a Cherry on the Mahaleb do well. As nearly all the sorts form handsome pyramids, and bear abundantly, I would advise this mode of training, as they can be confined to a small space and protected by netting. All the sorts are well calculated for planting against walls, and any aspect will suit them, but the more the south is deviated from, of course, the later the Cherries will be; so that where a succession is wanted it is well to have some upon all aspects. They may also be advantageously cultivated as dwarf bushes, pyramids, standards, or dwarf-trained, either upon walls or espaliers. As bushes and pyramids, when worked upon the Mahaleb stock, they are most prolific, and the fruit is generally larger, and a little later from it; all the tribes of Cherries succeed admirably on the Mahaleb, and can be kept in small compass as dwarf bushes; planted 5 to 6 feet apart each way, and covered with fine netting, the fruit can be preserved until thoroughly ripe. By a proper selection of sorts, as given below, the Cherry may be had in perfection from June till September; and, by adding the Morello tribe, from walls, until Christmas. I may add that Cherries cultivated on the Mahaleb stock, if occasionally lifted, will keep within a small space for many years. The branches require to be annually pinched back so as to cause them to produce fruit-buds close to the main stems, and also to keep them within reasonable bounds. The Morello is particularly suited for north walls, but it will bear heavy crops as standards, pyramids, or bushes. This variety of Cherry requires to have half its branches well cut back every year, and the other half left to bear fruit, as it is mostly upon the young wood that it is produced. All the Bigarreau and other large-leaved Cherries require, when trained, to be laid in very thinly, so as to give the foliage room. Some, however, lay the branches in from 9 to 12 inches apart, and depend upon cutting back for space to enable the young wood to be mailed in. Pyramids require very little pruning generally; shortening over-luxuriant shoots once a year in summer, and a due regulation of the branches in winter, are all they require. As standards they grow thinly and bear so abundantly that over-luxuriance is checked, and pruning is not much required. In forcing Cherries very little excitement is requisite, but plenty of air at all times. The following varieties, which are sufficient for ordinary purposes, are all of first-class quality and productiveness, and have been selected with a view to ensure a supply of fruit for cooking and dessert extending over the longest possible period:

Adam's Crown.—A medium-sized fruit, allied to the Geans, ripe in July. The fruit is of a pale red, and the tree a good bearer. One of the best of the early sorts.

All Saints.—A distinct variety of the Kentish class; the fruit is small, agreeably acid, and useful for cooking. The tree is very ornamental in appearance, and suitable for shrubberies.

Baumann's May.—A fine Gean, attaining maturity in June. The fruit is of a medium size, deep red in colour, and of the finest quality.

Bigarreau de Hildesheim.—A fine Bigarreau, ripening in September, and therefore valuable for its lateness. The fruit is of medium size, pale yellow on one side and deep red on the other, and of good quality.

Black Eagle.—A fine black Gean, ripening in July. The fruit is of a rich purplish colour, medium-sized, and very rich, juicy, and delicious.

Black Tartarian.—A large and handsome variety of the Black-Heart class, ripening in June when against a south wall. The fruit is of a deep blackish colour, and of the finest quality; one of the best for walls and forcing.

Bowyer's Early Heart.—A rather small Bigarreau, ripening in June. The fruit is pale in colour, but excellent in quality; valuable for its earliness.

Buttner's October.—A large Cherry of the black class. The fruit is of a fine reddish-brown colour, and of good quality for cooking. Valuable for its lateness, ripening, as its name indicates, in October.

Buttner's Yellow.—A medium-sized Bigarreau, attaining maturity in August. The fruit is of a pale amber colour, and good in quality.

De Charmeux.—A late variety of the Morello, with milder flavour. The tree forms a handsome pyramid, and bears abundantly.

Frogmore Early Bigarreau.—A large handsome variety of the Bigarreau class. The fruit is of a fine deep red on the sunny side, and of the finest quality; and the tree is a most excellent bearer. It is as early as the May Duke, and, therefore, most valuable for its earliness.

Governor Wood.—A fine Bigarreau ripening in July. The fruit is large, pale yellow mottled with red, and of excellent quality.

Imperatrice Eugenie.—A large handsome Cherry, closely allied to the May Duke, but earlier. The fruit is of a rich red colour, very sweet and juicy, and altogether excellent. It is one of the best early Cherries we have.

Kentish.—A well-known variety of medium size, ripening in July; and of the highest value for cooking purposes.

Mary.—A large and handsome variety of the Bigarreau class, ripening in July. The fruit is bright red in the sun, yellow in the shade, and of splendid quality.

May Duke.—A fine well-known variety of the Black Duke class, ripening in July. The fruit is large, of a fine deep red colour, and first-class quality. One of the best Cherries in cultivation.

Morello.—This also is one of the best-known Cherries we have. The fruit is of large size, fine deep colour, and for cooking of fine quality. It is one of the best for training to north aspects, and by protecting the fruit from the birds it may be left on the trees for a long time after it is ripe. It may also be grown as standards most successfully.

Reine Hortense.—A very large and handsome variety of the Red Duke class, ripening in July. The fruit is of a brilliant red colour, pleasantly acidulous, and of fine colour.

Werder's Early Black.—A large variety of the Black Gean class. The fruit is of a fine deep colour, very sweet, and of excellent quality. It ripens in June, and can be recommended for its earliness.

The best six varieties we have for small gardens are Baumann's May, Black Tartarian, Frogmore Early Bigarreau, Kentish, May Duke, and Morello.

JOHN SCOTT.

Merritt.

APRICOTS IN THE OPEN GROUND.

THE cultivation of the Apricot tree, especially in the open ground, is like a lottery—nothing is more uncertain. Of all the kinds of fruit-trees in general cultivation, it is, without contradiction, the one of which there is the greatest risk of seeing the crop fail; and that is easily accounted for. As its blossoms most usually in the middle of March, and sometimes earlier, its flowers are exposed to the late frosts which are frequent with us. It may, it is true, be grown on a wall, and protected with covering in bad weather; the chances of injury are then lessened, although not altogether avoided; yet, even so, what a difference there is in the quality of the fruit, which only attains its highest perfection of flavour when it has a full and free supply of open air and sunshine! In addition to the damage which a severe season will everywhere inflict on the blossoms of the Apricot tree, the tree itself will also certainly suffer from it, if the ground is cold and wet. In such soil it will push to excess during the summer, the wood will not have time to ripen properly, and, however slight may be the degree of inclemency of the succeeding winter, it will be liable to be injured so seriously that you may be obliged to cut away almost all the new wood. In the case of soils of this kind, there is a remedy of certain efficacy, and one which will enable us to succeed with our Apricots—not, however, without some expense. Dig holes $6\frac{1}{2}$ feet across, and $3\frac{1}{2}$ feet, at least, in depth. Fill them half-way up with bushes or faggots, small stones, or, better still, with brick-rubbish; plant the trees in these holes, covering the roots with good soil, just as in any other kind of planting; be careful, above all, not to bury the tree too deep; once planted it should stand on a little eminence. The materials underneath form an excellent drainage. The wood will then ripen properly, and you

may reasonably expect a crop one year out of three. That is not much, to be sure, but from the Apricot tree you must hardly reckon on obtaining more. The Apricot is usually grafted on the Plum; the Black Damsion and St. Catherine are the best stocks for this purpose. It is seldom grown on its own roots, as it attains a greater degree of vigour when grafted on the Plum tree. With the exception of the young wood, which is treated in the same manner as that of the Peach tree, all the other branches of the Apricot tree may be pruned in the same way as those of the Pear tree, always leaving them a little longer. The different kinds of Apricots vary but little in their time of ripening. The earliest do not ripen before the end of July, and the latest seldom pass beyond the middle of September. The following is a selection of the best kinds, given as nearly as possible in the order of their ripening:

Rouge precoce (Angoumois).—A fruit of excellent flavour, unsurpassed for forming delicious preserves. Ripens in the end of July. Tree, a most abundant bearer.

De Montgamet.—Somewhat larger than the preceding. Ripens in the end of July. The tree is very productive, and the leaves are more fringed near the stalk than in any other variety, a character by which it is easily distinguished. The fruit is generally used for preserving, and must be allowed to ripen well, when intended for the dessert.

Roman, also called Common, being the most extensively cultivated of all the kinds. It is almost always grown in open quarters, where it yields enormous crops in favourable seasons. In some localities it is grown on a most extensive scale, as it makes an excellent marmalade. Ripens in the middle of August. The tree is both vigorous and productive.

Royal.—Raised fifty years ago at Paris, in the gardens of the Luxembourg. A first-class fruit, ripening in the beginning of August. Tree, a most abundant bearer.

Peach.—An old variety, very productive and vigorous, well adapted for planting in places exposed to the wind—more so, perhaps, than any other kind. On a wall, it is hardly necessary to say that, although the fruit is larger and handsomer, it is not so good. This remark applies to all the varieties of Apricots in every locality. Ripens in the end of August and beginning of September.

Jacques.—Recently introduced. An excellent fruit, of rather small size, produced in abundance, and ripening in August.

Vigier.—Another new variety, of good quality, ripening in August. Tree very productive. It is a pity that such an excellent fruit has the defect of sometimes ripening imperfectly, one side being frequently found thoroughly ripe, while the other side is quite green.

Pouret.—About forty years in cultivation. An excellent fruit, rivaling the Peach-Apricot in quality. Ripens in August. Tree a good bearer.

With regard to the observations which I have made respecting the chances of obtaining a crop, all the varieties I have just mentioned may be grown as standards. For a wall, I should give the preference to the last five, which yield the finest fruits; and, as Apricot trees are not averse to warm aspects, they may be planted facing the south or west.

The pyramid form is not much used; it may be employed, however, but then the soil must be dry and well-drained.

Bourg-la-Reine.

F. JAMIN.

[The preceding is written by a very able and experienced cultivator, and is based on experience in the north of France; but, inasmuch as the Apricot is grown here and there as a standard tree in the market gardens of western London, it is probable that its culture away from walls on warm soils in the southern counties would be attended with a good result. Therefore we think M. Jamin's advice will be useful to such as are inclined to experiment in the matter.]

Pomological Literature.—As an instance of the imperfect character of our pomological literature, I may mention that I have searched in vain for Tom Put Apple in what is supposed to be the most authoritative Manual on varieties of fruits published in this country. It may be urged that the Apple is only of local fame, but, judging by recent correspondence in *THE GARDEN*, this is hardly the case. I submit that one of the main aims of such a work as that to which I allude ought to be the enumeration of such useful varieties as this.—F. T. S.

The Golden Noble Apple.—I am surprised that this handsome Apple is not more grown for market purposes than it is. The tree is robust and a good cropper, the fruit is of a good medium size, with a singularly clean, smooth yellow skin, and in shape it is perfect. I should imagine that good samples of this Apple would be eagerly purchased by greengrocers for window dressing, as it affords a pleasing contrast to the dark-coloured kinds. It is always a valuable kitchen Apple, but just now it is equally acceptable for the dessert; its flesh is white, crisp, and juicy, and it has a pleasant but slightly acid taste.—D.

THE FLOWER GARDEN.

A FERNERY IN THE ISLE OF WIGHT.

THE Fernery that has lately been made among the trees of St. John's House, the residence of Mr. J. P. Gassiot, is one of the most interesting which we know of. It consists of a sort of glass dome, which, at the highest point, is raised about 20 feet from the ground, while its circumference rests on jutting pieces of rock, or on a carpet of Heather, which flourishes around the spot. Its diameter is rather more than 40 feet. It is intersected by little paths, and has two main approaches—one upon the eastern and the other on the western side; they are so skilfully curved and cut out amidst sloping

will be one of the most attractive of its kind. Here also many beautiful species of British Moss find a congenial home, such as *Hookeria lucens*, *Leucobryum glaucum*, and many others. It is not every one who can afford to experiment in this way with rare and costly plants and Ferns; but, should they do well under their present circumstances, the experiment will not be without profit to many gardeners in the more genial parts of the country. Several plants will probably have "half-hardy" associated with their names which have not yet enjoyed such a distinction, and, perchance, many charming little bits of scenery, with natural rocks and water, Ferns and wild flowers, will be covered in with glass. The trickling of running water and the presence of singing birds among the Ferns, are added to

View in Fernery at St. John's House, Isle of Wight.

banks, as very greatly to add to the beauty of the place, and they seem to increase its size. In this Fernery some of the choicest Ferns and plants of New Zealand, Australia, and the temperate regions of India, China, and other countries are gathered together, and they seem to be as much at home as if they were in their native glens. Among the more prominent may be noticed *Dicksonia squarrosa* and *antarctica*, *Pteris umbrosa*, *Todea africana*, *Cyathea Smithii* and *dealbata*, *Davallia polyantha*, *Osmunda capensis*, *cinnamomea*, and *spectabilis*, *Woodwardia orientalis*, *Davallia tenuifolia*; and there is one gigantic Fern, which we believe is quite new in this country, and has not yet been named. It is about 16 feet high. Lilies, too, grow here, and *Cyclamens* from the Greek Isles are presently to be introduced into some of the multitudinous nooks and corners which abound within and without the Fernery, which, in time, when properly furnished,

the other attractions of the Fernery, which was formed by Mr. A. Blake, of Fulham. R. W.

ANNUAL FLOWERS AND THEIR CULTIVATION.

ALTHOUGH the most popular kinds of Annuals are employed in the flower garden, they are adapted for many uses to which they have as yet never been applied. There can be no doubt that the present expensive and sometimes monotonous and uninteresting style of garden decoration will soon give way to something better, in which Annuals may play an important part. A few misconceptions prevail as to the relative merits of this class of plants; for example, by some they are regarded as "weedy" and "short-lived," their very cheapness, and the comparatively small amount of skill required in their cultivation, tending in some degree to their detriment in public estimation. These plants come into flower within a short period of

time from the sowing of the seed, and a very large proportion of the best continue beautiful until the close of the season. Sometimes in the autumn Geraniums become "washed out," while Tom Thumb Tropaeolum (or Dwarf Nasturtium) may be ablaze with colour and continue so when the Geraniums are housed for the winter. A number of showy and long-lasting annuals may be selected for employment in the "bedding" system, and by a little management those that do not last the season out may be replaced by others for succession; they thus afford variety, and make no demand for glass and fuel to keep them through the winter. We have had great sheets of Candytufts, snow-white, rosy-red, and deep purple; when they began to wane they were removed, and the ground planted with Asters, and very soon there was another display, fresh and varied. Banks that would have swallowed many pounds' worth of greenhouse plants to cover them, have been made gay at a very trifling cost, by sowing upon them Tropaeolums, Sweet Peas, Convolvulus, Candytufts, Eschscholtzias, dwarf Poppies, and Clarkias; and damp half-shady borders have been delicately tessellated by means of Forget-me-nots, Venus's Looking Glass, Pansies, the rosy Oxalis, Nemophilas, and Scabious. For the more important positions in the flower garden we have choice of many handsome plants, such as Stocks, Asters, Balsams, Drummond's Phlox, Portulacacs, Zinnias, Erysimums, Candytufts, the lovely Scarlet Flax, Silenes, Tropaeolums (the true 'Tom Thumb' race offering a variety of colours), and many other plants equally beautiful and lasting. It should be remembered, too, that amongst annuals are found many richly-scented flowers; others, like the everlastings and the Grasses, are invaluable to dry for winter use, for employment in bouquets, and garlands in Christmas decorations; and some, such as the Sweet Peas for example, may be employed to cover arbours and trellises with fine effect, and may also be allowed to hang in festoons about the sunny parts of rockeries, or trail over the ground to make genuine bedding effects.

A number of plants of ornamental character, usually treated as perennials, are more effective, besides occasioning less labour to produce them, when cultivated as annuals. Several of the Campanulas are examples of this. The Indian Pink, again, and its several splendid varieties, do better as annuals than perennials. For ordinary purposes, blue Lobelias may be as well grown from seed as from cuttings. It may be observed that many annuals, reputed tender, and needing to be raised in heat, do very well indeed under or more rough and ready treatment. In proof of this sow *Perilla nankinensis* in the first week of May where it is required, and in the month of July you will probably determine that *Perilla* does not greatly need the careful nursing it usually obtains in heated houses through the spring. Even the really tender Castor-oil Plant (*Melissus*) will thrive if sown in the open ground the first week in May. Having no check, as plants put out from pots must have, the growth will be regular and sturdy, and they will attain great dimensions, and flower freely if the season is favourable. We recommend, not only a free use of annuals, where they can be appropriately employed for purposes of embellishment, but also the setting apart for a collection of them a border or plot, one part of which is sunny and another part partially shaded. On this border sow clumps of annuals, of as many kinds as possible, and affix to each clump a label that will last the season out, or enter the names in a book in the order in which the clumps are arranged, for purposes of ready reference. This border will afford much delight, for many annuals that are not "popular," because not particularly showy, will be found to be worthy of culture for their elegant forms and delicate blendings of colour.

Hardy Annuals.—These should be sown on a carefully-prepared surface, from which large stones and clods have been removed. Sow thinly, covering with a very thin coat of fine dry earth—the smallest seeds needing but a mere dusting to cover them—and, from the first, keep the plants thinned sufficiently to prevent overcrowding, which weakens them, and produces poor blooms. The soil into which they are transplanted for blooming should be deeply dug and well broken up; and if at all poor should be liberally manured. Spring-sown annuals are worthy of a better soil than they usually have allotted to them, as well as more careful treatment. It is not well to sow earlier than March, or later than the middle of April. The most important matter in the after culture is to keep the clumps well thinned; by early and bold practice in thinning, the plants will become so robust, and cover such large spaces of ground with their ample leafage and well-developed flowers, as to astonish people who may have ventured to designate them "fugacious and weedy." It is an excellent practice also to sow hardy annuals in September, and in this case choose a dry sheltered spot, from which they may be transplanted in March to where they are to flower.

Half-hardy Annuals.—Give these as long a period of growth as possible to ensure a vigorous plant before the season of flowering. We have had fine beds of Stocks by sowing in pans in March, and

planting them out in a very small state. But beds from seed sown in a gentle heat in January were far superior; the only important exception to the rule of early sowing is the Aster. It is bad practice to sow Asters until the end of March, or even the middle of April; otherwise early sowing is a good rule. The soil for the seed pans should be rich and fine. Good loam, improved by the addition of thoroughly decayed manure and leaf mould, with sufficient sand to render the texture porous, will suit all kinds of annuals that are sown in pans under glass. Sow the seed thin, cover very slightly, and lay squares of glass over them to keep a uniform degree of moisture without the necessity of watering. Should watering become necessary, take care to avoid washing the seeds out. If the pans or pots containing the seeds are placed for an hour or two in a vessel containing two or three inches depth of water, they will absorb sufficient, and there will be no occasion to pour water on the surface. A gentle heat is to be preferred, as too rapid a germination of the seed tends to the production of weak plants. As soon as the young plants appear, remove the glasses and place the seed-pans in the fullest light, where air can be given without danger to them. A dry east wind blowing fiercely over them will prove a blast of death. If they have no air at all, they will be puny, rickety plants, scarcely worth planting out. Choice varieties should be carefully pricked out into pans and pots as soon as large enough; this will promote a stocky growth, and a free development of flowers. Take care not to plant out until the weather is favourable, for any great check will make starvelings of the nurslings. If you cannot command heat for half-hardy annuals, sow the first week in April, and shut up the pans in a frame facing the south, and the seeds will soon grow and do well. If that is too much trouble, sow in the open border early in May, making the border rich and friable, that they may have a good chance from the first.

Greenhouse Annuals.—These require the same general treatment as advised in the last section. But it is advisable to sow earlier, and in a stronger heat than is required for annuals that are to be planted out. It is also necessary to be in good time in pricking out the young plants, for if they get much drawn they cannot make good pot plants. A light, rich, perfectly sweet soil, containing a fair proportion of sharp sand, will alone ensure plants worth having. It is also important to get them into separate small pots as soon as possible, and to shift them on to larger and larger pots, until they have sufficient pot room for flowering; after which pot no more. As soon as these pots are filled with roots, give very weak manure-water constantly until the plants are in flower, and then discontinue it, watering it with pure soft water only. Many of the commonest annuals are worthy of careful culture for flowering early in the greenhouse, but we have in view just now such fine subjects as the Camellia-flowered Balsam, Globe Anaranthus, Hibiscus, Ipomoea, Thunbergia, Pelargonium, &c. In illustration of the remarks made above, on treating many perennial plants as annuals, it may be worth observing here that if the seeds of the Zonal Pelargonium are sown in a heat of 60° to 70° in January or February (the earlier the better) the seedling plants will begin to bloom in the greenhouses in July, or nearly the whole will flower before November, thus affording an excellent display and the chances of a few novelties worth keeping. This mode of treating the plants saves the keeping of a number of plants through the winter. All those that are not regarded as better than the named varieties of their own colours may be destroyed as soon as autumn robs them of their beauty.

Biennials and Perennials.—These may be sown with success from June to August. A shady border, rather than under a burning wall, is preferable for the purpose. Use soil similar to that recommended for hardy annuals, and transplant as soon as strong enough into a sheltered spot, where they may remain during the winter. As early in March as the weather permits, transplant to where they are intended to bloom.

Asters.—It is only necessary here to say that they should have from the first a light, rich, porous soil. The middle of April is early enough to sow, and it is well to sow again at the end of April, and about the 9th of May, for a succession. If unusually fine plants are desired, prick out the seedlings as soon as large enough in a bed of rich soil, on a half-spen hot-bed, and by the time this is quite cooled down, the plants will be ready and may be lifted with good balls, and planted where they are to flower. The aphid has a great liking for the Aster, and fumigation may now and then be necessary. The best preventive is to keep the plants growing freely, with as much air and light as they will bear.

Stocks may be sown at almost any time—in fact, in every month of the year. For a grand bed and an early bloom, sow in February, on a gentle heat, and grow them on as recommended above for half-hardy annuals in general. A good bloom may be secured by sowing in a cool frame in March. Two things are important—first, a rich soil; and secondly, to plant out when the plants are very small—they should, in fact, make as much of their growth as possible

where they are to bloom. Plant rather thickly at first, and as fast as they show bloom, remove the single ones, and remove double ones also where too crowded, as room must be allowed for them to branch freely. For early spring bloom in pots, sow in August and September. Bear in mind that Stocks are nearly hardy, and, therefore, should never be placed in a strong heat.

Chinese Primulas.—These charming plants may be brought to the highest perfection by the most simple means. It is a great point to give them a long period of growth before they flower, hence they should never be subjected to a forcing temperature, and, in fact, should be treated as nearly hardy, but should have ample protection against frost, damp, and cutting winds. In order to enjoy the bloom of these Primulas for a long period, make at least two sowings of seed, the first in March, and the second in May. Further sowings may be made, if required, in June and July. Sow on a rich fine soil, and cover with a mere dusting of fine earth, and every seed will germinate, but, if buried deeply, much will be lost.

Cinerarias.—These need nearly the same treatment as Primulas. Frost, damp, and greenly are their principal enemies, but they are so nearly hardy that artificial heat must be afforded with great caution. Sow in April for plants to bloom in winter, and in July for a bloom in the later spring months. The July sowing will be the most valuable to those who have small gardens, as the flowering of the plants in the depth of winter makes a tax on greenhouse space, when it cannot be well spared. But Cinerarias produce such a brilliant display during the dark days of winter that accommodation should be found for them if possible.

Calceolarias.—May be treated as annuals, and by eliminating all the inferior plants as soon as they have flowered, a collection may be formed of original named varieties, from which valuable novelties may from time to time be selected. Sow the seed in July, in well drained pans. The seed should not be covered, but be put under a hand-glass, or in a close, shady corner of a frame. The seedling plants may be pricked out into a bed of turfy loam, in a frame for the winter, making no demand upon the greenhouse for their keeping; or they may all be potted and wintered in the house, in which case they will begin to flower in May.

Cockscombs.—Sow in rich light soil, in March or April, and plunge the pots in a smart hot-bed, or place them in a warm propagating house. It is impossible to grow fine Cockscombs by "cool treatment." The secret of producing large combs on small plants, with healthy leaves, consists in putting them on into larger and larger pots as they require it, each time putting them a little deeper in the soil, and maintaining a moist atmosphere with sufficient heat.

Pelargoniums of all kinds are most valuable, treated as annuals, as in their seedling state the plants are peculiarly robust and tree-like, and charmingly fresh in leafage and flowers. When grown from good seed a large proportion of fine varieties and a few real novelties may be expected. The seed may be sown on any day throughout the year, but the two best seasons are February and August. Sow in pans filled with a good mixture, in a somewhat rough state—if the surface nodules are as large as Horse Beans it will not be too rough. Cover with a sixteenth of an inch of fine soil. Put the seed-pans in a heat of 60° or 70° if sown in February, but heat will not be necessary at all unless it is desired to bring the plants into flower early in the ensuing summer. We have been accustomed to sow about the 10th of March, and place the seed-pans on a sunny shelf in a cool greenhouse, and have fine plants by the end of June.

Balsams.—These should never be sown too early, certainly not before the first week in April. The soil must be of a very porous nature, and to secure this use a good proportion of silver sand. As soon as the seed-leaves are fully expanded the plants should be transferred to well-drained pots, and should be inserted so deeply in the soil, that the leaves only appear just above the surface. Keep close for a few days, in a temperature not exceeding 65°. Afterwards give air as they begin to grow, and take care to keep the plants always close to the glass, otherwise they will become drawn. When well established they will require to be re-potted about once a fortnight, for the pot-bound condition is injurious to them.

Hollyhocks.—Sow in pans in January or February, and as soon as large enough, pot singly into thumb-pots. Re-pot the plants as they gain strength and size, and plant out into well-trenched and highly-manured borders about the middle of May, selecting showery weather if possible. They will then flower the same year, and thus save one year's growth. Or, if sown in August on a warm border, they may remain until April, when they should be planted where they are intended to flower.—"Sutton's Amateur's Guide."

Saxifraga Burseriana.—The flowers of this beautiful little Alpine are just beginning to make their appearance on the rock-work in the York Nurseries. They are of the purest white, while the bud is of a dull scarlet, borne on very short slender scarlet stems, which

spring from miniature rosettes, composed of very small rigid greyish leaves. This species of Saxifraga thrives best when planted in a compost of loam and limestone, with a slight admixture of peat. Although in its native habitat, I found it thriving in a shady situation, with a northern aspect, at an altitude of about 6,000 feet; in this country it should be fully exposed to sun light, for, when grown in the shade, it loses its compact, rigid habit, in which its beauty resides.—R. P.

Do Christmas Roses Seed P?—The seeding of *Helleborus niger* is not considered an unusual occurrence even in this part of England (South Lancashire). In some seasons it seeds abundantly in the gardens at Lathom House; and about two years ago the gardener (Mr. Kefford) saved upwards of half-an-ounce of seeds from his plants. I also saw it seeding profusely in a garden near Ormskirk, and seedlings in abundance sprang up round the plant. There is no doubt that seedlings of this plant, when brought to flower, would seed abundantly, as I believe there is a tendency in many plants to become sterile through long propagation in every way except by seed.—THOS. WILLIAMS, Bath Lodge.

Note From Cauntou.—The Rev. S. Reynolds (now Canon) Hole, in writing to us on other matters, remarks:—"That sweet little *Gentiana verna* (it should be *Gentiana hymalis*), in its determination to distinguish itself as President of the Alpine Club in our rock-garden has exhibited a bright azure star, which 'twinkles to the wintry moon, and cheers the ungenial day.' We are very busy, now that a few impetuous and breezy days have dried our sodden soil, in transplanting the best lot of *Rose trees* I ever possessed. There rode by our boundary, the other morn, a youth in a crimson coat, and when he saw a large fellow-creature holding that which seemed to him as a dry stick in his hand, and gazing thereon with rapt admiration, he quickened his pace, as though he were nearer lunacy than he liked, and Cauntou was Colney Heath."

New Verbenas.—At Mr. J. Fraser's nursery, Lea Bridge Road, we noted, during the past summer, some *Verbenas* adapted for bedding; they were German varieties, and seen to have inherent vigour of constitution, such as our English varieties once had, but which many of them now lack—a fact which, perhaps, accounts for the neglect into which they have fallen. Some of the most distinct were:—Baron von Bookheim, bronzy-scarlet; Rudolph Brandt, purple, with white eye, somewhat recalling the fine old bedding plant of yore, *Lantana Selloana*; Moritz Schulz, deep claret, with small white eye; Baron von Apraxine, rich violet; Hofgarten Noak, rosy-pink, pale scarlet eye; Baronin von Paussinger, rose with crimson eye; Alemaine, deep rose-pink with white eye; Theodor Emmel, light vermilion, with white eye; Paul Vas, deep scarlet with dark eye; La Loire, maroon with white eye; and Gruss van Strassburg, orange-scarlet with large white eye. These may be recommended as well worth a trial.—"Florist."

Blue-flowered Hydrangeas in Cornwall.—In a place in Cornwall, where I was for some years, *Hydrangeas* grew very freely and attained a large size, in the shrubby borders where the ground was not dug or otherwise disturbed. Of these bushes many were 4½ and 6 feet high, and as much through; they usually began to expand their bloom during the latter part of August, and when the seasons were favourable the later opened flowers (those that expanded in September and October) would keep fresh and effective on to and after Christmas. In one portion of the ground the blooms were always blue, and, as strangers generally remarked, a pleasing light blue, such as is seldom seen in the case of any other plant. I frequently used these flowers for Christmas decoration, and associated with the red berries of the Holly and the greenest leaves at command they had a fine effect. On enquiry I learned that the plants which grew in that particular part of the ground had always produced blue flowers, while those in other parts of the ground always produced flowers of different shades, varying from blue to dull creamy or dirty white; on many occasions did visitors have cuttings from the blue flowering plants, but they did not produce flowers like those of the plants from which they were taken; the blue flowers are doubtless due to the presence of some particular ingredient in the soil. I ought to add that the plants which produced blue flowers grow under some very lofty trees, and, no doubt, the particular shade of blue, with which all were so pleased, was brought out all the better from the flowers not being exposed to the full glare of the mid-day sun.—G. DAWSON.

Hardiness of the White Lapageria.—At Gunnersbury Park a leading shoot of the white variety of *Lapageria rosea*, planted out in a low span-roofed house, has found its way outdoors, and grows vigorously against the outside wall at the north end of the house. It passed the winter of 1874-5 unscathed, and during the past summer it grew with great vigour. I have not seen it lately, but have no doubt it is still flourishing. Does not this circumstance indicate that the *Lapageria* possesses greater hardiness of constitution than is generally ascribed to it?—R. D.

THE KITCHEN GARDEN.

ASPARAGUS CULTURE IN INDIA.

In a little pamphlet by Messrs. Barnes & Robinson on the culture of Asparagus in England, Ireland, and France, the different modes of growing that esculent are pointed out in such a manner as to be intelligible even to a fidgety amateur gardener just commencing to take an interest in his newly acquired plot of land. But to make it more complete and useful, a note might perhaps be added to a third edition showing how the profitable cultivation of this desirable vegetable might be extended to India—say to Madras, Bangalore, and Mysore, where partial success has on several occasions been gained.

The temperature at the former place is very high, so much so that it has been said that for three months, the climate is hot, but bearable in a large and well-appointed house, and, for the remaining nine, excessively hot and unbearable. Aided by an almost constant sea-breeze for some part of each day, Dr. Cornish succeeded in growing "Grass" of the giant kind, and not only in growing it, but in getting a cutting from the beds in seven months from the date of sowing the seed—a kind of forcing that even Frogmore may envy. I understood him to say that he got continued cuttings of fair-sized heads for some time afterwards, even during the hot weather, the details of which he communicated to the editor of the "Madras Mail," who published the account, of which I am sorry I have not a copy to send you. A similar trial was made at Bangalore by Colonel Pearse, who had a cutting in about the same time, from seed that Mr. Bull sent out. The plants were bedded out in Celery trenches, and under a liberal allowance of water and manure, and with a hot sun overhead, the growth was very luxuriant. But, in my judgment, sufficient room was not given for the root formation of each individual plant, and the early produce, though many of the heads were of fair size, was insipid—as immature food of every description generally is. This insipidity was, doubtless, due to the quickly forced growth. It would probably have been more in accordance with the dictates of Nature to have allowed the roots a longer period for healthy development, before any attempt was made to cut a dish of Asparagus from them; but, from an amateur point of view, it was something to be able to say that such had actually been done in little more than half a year, when, in England, it is generally considered that two and a half or three years must elapse before such a result can be obtained. Major Johnson also raised, at Mysore, very fair Asparagus under much difficulty. I have no note of the time it took him to mature his plants, but I think he would look more to solid results than to a sensationally early crop. It will be fair to predict that the constitution of the plants under sensational treatment

would be quickly ruined. A professional gardener would not probably permit such a strain to be made upon them, and with good reason, as it appears to me. What is required is to understand thoroughly what the practical treatment in India should be, so that market gardeners there might be able to undertake the culture of this delicious vegetable on such a scale that the market shall be abundantly supplied, and their labour and outlay well repaid. It is on this point that practical information is eagerly sought, and I invoke your aid, and the aid of any interested readers of THE GARDEN who may be willing and able to give it in your columns. From what has been already done, there seem to be reasonable grounds to believe that Asparagus culture may be profitably undertaken at Bangalore, and perhaps at Madras, and that in time the market may be supplied with fresh grown instead of canned "Grass." It would create a new industry for the market gardeners, who are very painstaking and intelligent, and who deserve every support that can be fairly given to them, and a plentiful supply of it would be a welcome addition to our vegetable food in a far-away land. I forgot to say that the growth at Madras and Bangalore was equally luxuriant, although the climatic conditions are so essentially different. The sea breeze at the former place was more congenial to the habit of the plant than the air of the inland elevated plateau of the Mysore Province, and made up in some way for the greater heat it had to endure on the coast. Perhaps the necessity of adding special saline manure in sufficient quantity was not thoroughly understood at Bangalore, and this is a point on which practical information is specially desired. From a comparison of the French and English systems, I would argue that at Bangalore the French plan would be most likely to succeed; but, instead of growing the Asparagus among the Vines, it might be grown in rows, between lines of the medium Castor-oil plant, or of *Cajanus indicus* (garden variety), either of which would give a grateful protection from sun and wind, and, at the same time, yield a fairly profitable extra crop. Mulching, in all its different

Rest-spores of the Potato Fungus.

forms, might also be added with excellent effect during hot weather.

REST-SPORES OF THE POTATO FUNGUS.

By W. CARRUTHERS.

THE structure and life of the *Peronospora infestans*, as found on the foliage, haulm, and tubers of infested Potatoes, have long been well known, and have been frequently described; but the conditions under which the life of the parasite is continued from the autumn to the following summer have been the subject of frequent, persevering, but hitherto unsuccessful research. At the instigation of the Royal Agricultural Society, Professor De Bary has renewed his investigations in this direction, and has arrived at important, though yet unpublished,

J. P.

results. So obscure has this part of the life of the fungus been that some investigators have doubted whether the plant was a true *Peronospora* at all, and whether the desired information would not be discovered in some well-known fungus parasitic on a different group of plants from the Potato, and whose connection with the fungus of the Potato disease had not yet been suspected. The importance of Mr. Worthington Smith's discovery is all the greater that the subject was surrounded with so much obscurity. By the help of the engraving and of specimens that Mr. Smith has placed at my disposal, I am able to place before my readers the result of his addition to our knowledge. It was in investigating the new aspect which the disease had assumed in some, especially in some American, varieties of Potato that Mr. Smith discovered the rest-spores. With the view of separating the tissues for more exact examination, he placed in water some of the diseased leaves obtained from plants grown at Chiswick. He observed that the mycelium grew with greater rapidity in the water, and after ten days he found it producing a large number of minute spherical bodies of two kinds, the one considerably smaller than the other. He further observed specimens in which the already known fruits of *Peronospora infestans* were growing from the same mycelium as the newly-discovered bodies. One of these specimens is drawn in our illustration. There consequently remained with him no doubt as to the relation of the spherical bodies produced by the mycelium in the substance of the leaves to the *Peronospora*. These bodies exactly correspond with the sexual organs that De Bary had already described in several species of *Peronospora* under the name of oogonia for the larger, and antheridia for the smaller bodies. Mr. Smith perceived that he had discovered the sexual organs in this species of *Peronospora*, and continuing his observations he traced the relation between the two bodies. He observed the small antheridia attaching themselves to the oogonia and fertilising them, by discharging part of their contents into the larger cells through a small tube which was protruded into the substance of the oogonia. The growth of the fertilised oogonium, now called an oospore, was traced by him until it arrived at maturity, when it is a spherical body covered with warts or coarse reticulations and of a black-brown colour. It is but slightly larger than the cells of the leaf, being about one-thousandth of an inch in diameter. When the rest-spores are mature, they separate themselves from the mycelium on which they grew, and lie as free bodies in the substance of the Potato. And when, in course of time, the whole of the plant perishes, these small hardy bodies remain, able to endure through the winter, and ready to renew the life of the destructive fungus with the restored vegetable life of another year. Mr. Smith has found the rest-spores in the haulm and tuber as well as in the leaf. Having thus discovered the means by which the fungus maintains its life through the winter, we are able to look at the question of the possibility of doing something efficiently to mitigate if not destroy the evil. The malady which so extensively destroyed the silk-worms in the south of Europe some years ago, was unconsciously augmented by the producers throwing the dead worms together and keeping them within the establishment, thus increasing the conditions favourable to the growth of the fungus, and to the unlimited development of the spores. It was not until, by the advice of botanists, they cleared away from their silk-worm houses every dead insect and withered leaf, and cleaned the walls that they got any mastery over the disease. So we have been unconsciously harbouring the Potato disease in permitting the haulm and foliage to decay on the field or in manure-heaps, which left the undecaying oospores behind ready to start into life when the proper conditions were present. Every care now should be taken to destroy, by burning, all diseased haulm; and as diseased tubers also harbour the rest-spores, these should be utilised in some way in which the spores could not be injurious, as by employing them in the manufacture of starch or British arrowroot. A vigorous and universal attempt thus to deal with the fungus might now greatly reduce the future liability to, and extent of, the disease, though it can never, I fear, deliver us entirely from it.—“Journal of the Royal Agricultural Society.”

MR. CARRUTHERS' REPORT ON THE POTATO DISEASE.

If all who have cures to offer for the Potato disease were to study Mr. Carruthers' report on the subject (see p. 42) for the future, a vast amount of useless writing would be spared. Genuine enquirers after the truth, as regards this terrible pest, have hitherto had to encounter such masses of absurdities as to have nearly put them off the proper track. Mr. Carruthers' report, although all the conclusions at which he arrives are not new, must, let us hope, set aside all such obstacles. In the first place, all the essays have proved

failures, and the writers of them will not have been made happier by the report in question. Secondly, of disease-proof kinds of Potato, we shall hardly hear much in future. Again, the notion that the disease is propagated by planting partially-diseased tubers is disposed of; and, still further, it has been most conclusively shown that change of seed offers no safeguard, for all of the 6 tons in question were grown elsewhere than where they were raised; a more complete change of soil could not be had. Moreover, the notion that soils of a certain character are more or less favourable to freedom from disease, apart from excess of moisture or other climatic causes, is shown to be baseless; as is also the belief that patent manures have any disease-resisting qualities; in fact, there is no point left untouched, and the whole question is now so narrowed that it will be sheer waste of time and space to go over any of the old ground again. To one fact Mr. Carruthers points with considerable emphasis; but it is, after all, one which all are familiar, and that is, that the disease is more or less virulent in proportion to the amount of rainfall. Mr. Carruthers' inferences as to the existence of the living spores of the fungus in the air and their fertilisation on the leafage of the Potato by means of rainfall are identical with the views put forth by me in the “Daily News” some years ago, when I pointed out that the spores were floating about in the air, and only waiting for favourable conditions, namely, those of a humid atmosphere and a softened cellular tissue to settle, and become the instruments of vegetable destruction. A conclusive proof as to the agency of rain in promoting and feeding fungus growth is found in the fact that Potatoes grown under glass at the same time of the year, but fully exposed to the air at the sides and abundantly watered with pump water, remain healthy and vigorous; Mr. R. Fenn, of Woodstock, who was one of the first to demonstrate this fact, invariably grows his fine seedling crosses the first year under glass in order to ensure their safe maturity. In reference to a statement made in the report that where seventy bushels of soot per acre had been used the crops were almost free from disease, it should not be forgotten that our leading growers for exhibition invariably use a considerable quantity of both soot and lime for their Potato culture, both being conducive to cleanness of skin. Their heating and absorbent qualities have also been proved to be a considerable check to the growth of disease in the tubers. For healthy Potato culture, I know of no better conditions than good sound well-stored seed; soil moderately dry, deeply stirred, and well pulverised, that has been liberally manured for a previous crop; room between the sets in proportion to haulm growth, but rather too much than too little; and sharp ridging with the moulder when the haulm is sufficiently high, if under field culture—or with the fork, if planted in the garden. Add to this, if you will, a liberal dressing, just before planting, of a mixture composed of two parts screened wood-ashes, and one part each of slaked lime, soot, and guano, all of which will greatly assist in the production of clean tubers. Unless wanted for immediate use, or for marketing, it is sheer folly to lift the crop before it is ripe, in the hope of entirely saving it. The only result is the expenditure of a large amount of labour uselessly, as the Potatoes that would have rotted in the ground will decay all the same after storing. Our expectation that the disease may ultimately be checked is based on the hope that when its seat when at rest in the Potato is discovered, we may be able to attack it with greater advantage than when growth is active. What we want is an exact knowledge of the action of the disease under all circumstances; and when that shall have been ascertained, the victory will be nearly gained. Although the disease has been amongst us for more than thirty years, we are only just beginning to fairly grapple with it, and I trust that it may be to good purpose.

ALEX. DEAN.

Heeling-in Broccolies.—The heeling-in of Broccolies in winter is considered by some to be of little use. In my experience, however, which extends over many years, I have found great advantages from it, especially in the case of the early varieties, such as Snow's Winter White, Backhouse's Early, and the Penzance. These sorts are generally planted closer in the rows than other kinds, and are, therefore, drawn up; but, by heeling them down close to the ground, with their heads to the north, and putting a wisp of dry

Fern or hay in every head, they are preserved safe during the severest frosts. I never treat late sorts in this way, such as Catlett's Eclipse, Carter's Champion, and others, for they are grown sturdy in wide rows, and by earthing their stems well up, they generally stand severe frosts without injury.—WILLIAM TILDLEY, *Welbeck*.

THE FRENCH EARLY HORN CARROT.

I SHOULD like to see this Carrot more extensively grown than it appears to be. I would especially recommend a trial of it to the owners of small gardens, as likely to give satisfaction both as regards its intrinsic qualities and its productive capabilities. I venture to assert that those who have habituated themselves to a supply of this root during the spring and summer months will not easily make up their minds to forego the luxury. Coming as it does at a season when fresh crisp vegetables are comparatively scarce, it seems to me to really merit that title. In all French kitchens this little Carrot is almost indispensable, and this is not to be wondered at for both its appearance and flavour are tempting, and fully justify the high estimation in which they are held. The first crop, where it is possible, should be sown on a moderate hot-bed in January, taking care that the soil employed is tolerably rich and well sweetened—the best material I have found for this purpose is the clearings of old hot-beds which have been turned over and over for several years, and have become reduced to the consistency of mould. Where a supply of this does not exist any kind of free well worked soil may be taken. When the seed is up thin out to about 4 inches, and care must afterwards be taken to admit plenty of air on all favourable occasions, so as to prevent drawing and covering up in cold weather. The first sowing in the open ground should be made about the middle of February, choosing a well sheltered and rather dry spot. Thoroughly break and pulverise the soil, which should be fairly rich; it is well to fork in a good dressing of soot and lime, which give substance to the tops and will free them in a great measure from the ravages of grubs. The seed may either be sown in a 4-foot bed or in drills; if the latter be preferred they should be drawn with a good broad hoe making them as wide as possible. It is advisable to sow the seed moderately thick to ensure a plant, thinning when up to about 4 inches. By leaving them thus they may be drawn as soon as the flavour is well defined. By thinning out methodically and regularly over the whole bed, in this manner a small piece of ground will yield a continuous and lengthened supply; in fact, it is surprising what a quantity can be grown on the space; by leaving them rather thick they can be pulled early, which forwards the season, and as the crop advances in size, so, from the constant thinning they acquire the room necessary to their development. It is, however, preferable not to depend upon one crop, and successional sowings should be made in the beginning and latter end of March, and again in April. The same rule that regulates the sowing of salads should be applied to them. Weeds should never be allowed to encroach upon them, and a good soaking of water in hot dry weather will greatly benefit them; in this manner a continuous supply of fresh young Carrots may be kept up during the whole of the season.

Byfleet.

JOHN CORNHILL.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

To Keep Potatoes from Sprouting.—Where seed Potatoes cannot be spread out thinly, which is, of course, the best plan, it is astonishing what an influence simply turning them over has in checking premature growth, if it is only done in pits.—E. HODDAX.

Iron Cinders or Clinkers for Garden Walks.—These form good foundations for garden walks or roads—a good depth of them in the bottom ensuring efficient drainage. Thus treated the walks present a dry firm surface after the heaviest rain, and they are not only pleasant to walk on, but Moss and weeds seldom trouble them.—J. GROOM.

The Shanghai Wheelbarrow.—Our garden wheelbarrow is, it appears, likely to be superseded by one of Chinese origin, introduced from Shanghai. The wheel is so arranged as to lighten the strain on the arms, and enable the load to be largely increased without increasing the labour. Can any of your readers say where I may see a specimen of this barrow, or send you a sketch of it for engraving?—J. H.

Pooley's Prolific Dwarf French Bean.—I grew this for the first time last summer, and can recommend it as one of the best for out-door cultivation. Its pods are long and slender in shape, and very productive and durable. Being of a fine green colour, it is better adapted for exhibition than any other with which I am acquainted; and the seeds, while green, are valuable as Haricots.—W. C.

Laxton's Standard Pea.—This Pea is not of yesterday's acquaintance; on the contrary, I have grown it both late and early for three years. Sown thinly, and stuck with good 3 feet stakes, in good rich soil, it quite covers its supports, and is literally loaded with Peas from bottom to top. The average number in one pod is nine, and many have even, and a very best flavour. Being dwarf, it takes up but little room; and although great numbers of Peas are before the public, this standard Pea is the one for the cottager, or for others who have small gardens.—R. GILBERT, *Burghley*.

KENSINGTON GARDENS AND LONDON TREES.

AN "Indian Forester," writing the other day to the "Times" in reference to Hyde Park and Kensington Gardens, says:—"It needs only a moderately intelligent examination of the wooded portions of Kensington Gardens, to notice that a large majority of the best trees are rapidly dying. The evil is not equally apparent in all parts, but in places it stares one in the face. If we take, for instance, the trees between the Albert Memorial and Kensington Palace, it is not too much to say that above 80 per cent. are diseased or dying. One remedy, indeed, seems to have been tried as a sort of panacea, and that is lopping and cutting off the tops of the trees. Besides producing, in many instances, the most hideous stumps, it is by no means certain, not even very probable, that this remedy is effectual, the spurt which the tree puts in sending out shoots near the cut being purely temporary, and likely to be soon exhausted. Great numbers of the trees now standing ought to be removed, or they will become absolutely worthless, and I would urge the formation of a small committee of practical and experienced foresters, including some experts in landscape gardening to look into the matter. The requisites for a remedy are, to avoid rash and empirical conclusions as to causes, and to substitute accurate and recorded data and observation of fact."

Mr. C. D. Hudson, of 51, South Audley Street, states that the "Times" correspondent just quoted has omitted to mention one fertile cause of the premature decay of these trees, which is the fact (and there is unmistakable evidence to prove this) of their having been greatly overcrowded during the earlier stages of their growth as well as subsequently. That this has borne an important part in shortening their lives is apparent by an examination of those trees which stand out singly, not only in Kensington Gardens, but in Hyde Park, the Green Park, and other places in London, where very fair samples of trees of equal age with those in Kensington Gardens may still be seen in a tolerably healthy condition. The longest lived and healthiest trees are invariably to be found among those which have sufficient room both for their roots and branches. But what we have now to consider is the description of tree to be used in re-planting. There is only one tree which really flourishes in London, and that is the Oriental Plane. If anyone wishes to prove this, let him make a tour round our squares and parks. Let him examine the Planes planted in Hyde Park, the few to be found here and there in Kensington Gardens, and in the Green Park along the side of Piccadilly, where there is a continuous row of alternate Planes and Elms. He will find that everywhere alike this tree is outstripping its older rivals. Finally, let him look at the magnificent specimens in Berkeley Square. In fact, these trees are hardy, of rapid growth, and attain first-class dimensions, and what is of the greatest importance, are not affected, owing to the annual shedding of their outer bark, by a smoky atmosphere. I would not banish every other description of tree from our parks; other kinds might be sparingly used. For instance, the White Birch, with its beautiful bark and graceful sprays, might with great advantage be introduced on the fringes of the new plantations; but unless the great mass of the new trees planted consist of the Plane, our efforts for the restoration of the Kensington Gardens' forest will most surely end in disappointment.

In reference to these statements "W. R." remarks:—"Kensington Gardens are certainly in a bad state, but they cannot, I fear, be made better by the roundabout and tortuous methods proposed by "An Indian Forester." It is no more necessary to take all his precautions than it would be to institute similar ones to secure the good management of a ship. In each case what we want is a good man who knows his business. Planting in most of our parks is sadly neglected—at least, in all its nobler aspects, while great expense and skill are lavished on myriads of plants that live for the summer only, in those long and often stiff-looking masses that stretch along by Piccadilly and elsewhere during the summer. The true remedy for the present state of things is the annual planting of a certain portion of ground in each great park, beginning naturally with the worse parts. That portion should be thoroughly cleared, prepared, and planted. We should thus secure perpetual growth and vigour, as well as stately beauty, in our park trees. Stealing out a dying tree here and there, and stealing in a young one—often done in London parks—is a great mistake. To clear a portion of the ground and plant annually a group or family thoroughly well is the only satisfactory way. Frequently there are open bare spaces left unplanted for years, as for example, Primrose Hill, which is as bare as a great inverted basin. There is much that might be said on this matter, but I hesitate to intrude on your space.

[Mr. Hudson's statement that "there is only one tree which really flourishes in London, and that is the Plane," is contrary to fact, and may, if acted upon, lead to great harm. No doubt the Plane is one of our noblest trees, and, for certain positions in towns, on the

whole the best; but many others thrive perfectly in London, and London Parks with one fine tree would be too like a world with only one type of beautiful face. "Only one tree that really flourishes in London!" Mr. Hadson cannot surely have seen those beautiful and healthy old Hawthorns, in Kensington Gardens, that last May swarmed with rosy buds and blossoms, as fresh as ever grew in the open country. Why, anyone who strolls through Kensington Gardens on a late spring or early summer morning may see a whole arboretum of trees in the most perfect health. The best living collection of the various kinds of Ash trees, American or European, that I know of, is in Kensington Gardens, and all in perfect health. There are Horse Chestnuts, which were towers of silvery spikes last summer, Maples in variety, Almonds and double Peaches that make the shrubberies sparkle with warm hues in spring; double Cherries with soft snowy blossoms, and Laburnums with golden rain. All the Maples tried are quite at home, and so are many other deciduous trees, such as the Locust and Honey Locust trees; as stately as the Planes, and more picturesque in habit are the great Poplars particularly fine at the lower end of the Serpentine, and also in the Green Park, near Piccadilly. If it were desirable, it would be easy to enumerate a host of beautiful trees that thrive in these gardens. The fact is there is no deciduous tree that inhabits the northern regions of the earth which may not be grown in London if properly planted and placed in a suitable position. Evergreens, with few exceptions, perish from the action of the London smoke in the long winter and spring months—an evil which all the trees that shed their leaves in autumn escape. The evils that affect the trees in Kensington Gardens—old age, injury from overcrowding or from exhaustion of the ground, or from the trees being in unsuitable positions—are such as would work like results everywhere else. The great want, however, is the regular annual planting of a certain portion. The old trees in Kensington Gardens, like the old men and women mentioned in the obituary of the "Times," die at last, and if we fail to raise an annual crop, decay soon begins to be disagreeably conspicuous. Even the difficulties of planting in the very heart of London are exaggerated. In Printing-house Square, under the very windows of the "Times" office, are trees of the American shrubby Trefoil (*Ptelea trifoliata*) as healthy and as large as we have ever seen them in any collection in this country. Look at the beautiful Weeping Ash trees in Brunswick Square and elsewhere in West-central London, and the excellent Catalpas seen here and there (in the Marylebone Road, for instance), that are covered with handsome blossoms and large shade-giving leaves. Look, also, at the Hawthorns and other trees of the Rosaceae Order in the Botanic Gardens, Regent's Park, where the soil is very cold and stiff, at the Sumach, Pyrus, Medlars, snowy Mespilus, Bird Cherry, Tulip tree, Sir Charles Wager's Maple, Flowering Ash, and many other trees, which anyone who cares about trees may see thriving in London. There is, indeed, ample proof under our eyes that not one, but hundreds of different kinds of trees may be grown in perfection in our London parks. Nothing would be more fatal to the beauty of these than exclusive adoption of one or even several kinds of trees. Let us have plenty of Planes, by all means; but also let us enhance this stately tree by contrasting it with the splendid wealth of tree-form and blossom now introduced to our gardens. Let one-fifth of the means and skill now devoted to the building of glass-houses and the culture of tender plants in London parks be diverted to the systematic and judicious planting of hardy trees; and, in due time, the parks of London will become the finest Arboretum of deciduous trees in the world, for there is no city where they thrive better, no city with anything like the same grand opportunities for planting.—W. R.]

Coleworts, Peas, and other Market Garden Crops.—I am not surprised to hear that Mr. Gilbert grows a large amount of Coleworts, knowing the opportunities which he has of doing so, and how he realises their value; but my remarks applied rather to the great mass of gardens in the country than to kitchen gardens like that at Burchley, where no useful vegetable is neglected. Mr. Gilbert, however, does surprise me when he writes that, as a rule, "market gardeners do not grow Peas." Probably market fruit growers, like Messrs. Dancer and Wilmot, and even Steel, do not do so; because, with them, vegetables constitute accessories rather than staple crops; but, in my own immediate locality, matters are different, inasmuch as here, in the majority of cases, vegetables are much more extensively grown than fruit, and Peas, especially, are grown upon hundreds of acres, constituting, not farm, but market garden crops. At the height of the last Pea season one of my neighbours sent up to market daily 1,000 bushels, whilst smaller growers also furnished immense quantities. Already, where Coleworts have been cleared off the ground is being manured and prepared for early Peas and Potatoes, and these will be succeeded by Broccoli, Cole-

worts, &c., and so on from year to year, the chance of a crop being made to depend more on high cultivation than on rotation. Peas, Potatoes, and winter Greens are the great staple crops in this locality. Of course, however, many other kinds of vegetables are grown, but not so extensively.—ALEX. DEAN, *Bedfont, Hounslow.*

NEW PLANTS, &c.

Crassula Bolusii.—A small-tufted south African species, bearing little clusters of pale lilac flowers. The oblong-lanceolate fleshy leaves are curiously spotted with dark green and are fringed with short hairs. It grows and flowers freely, but is not showy. "Botanical Magazine," t. 6, 194.

Rubus Roezli.—A smooth-branched shrub, with palmate-lobed leaves and creamy-white flowers the size of half-a-crown. It was discovered in Colorado by M. Roezl. "Gartenflora," t. 837, pl. 2.

Staphylea colchica.—A hardy shrub from the Caucasus, nearly allied to *S. pinnata*, having ternate bright green leaves and racemes of delicate white flowers of wax-like texture, the four petals forming a tube around the stamens. Grown in pots it is valuable for forcing, by which operation the flowers acquire a peculiarly delicate frosted appearance. "Gartenflora," t. 837, pl. 1.

Pescatorea cerina.—A showy white-flowered Orchid, having plicate bright green leaves and large wax-like white flowers, the column being of a deep crimson colour, and the yellow lip has a series of erect purplish-brown plates at its base. South America. "Gartenflora," t. 838.

Thibaudia Hendersonii.—A branching shrub, having alternate, ovate three or four-nerved leaves, and terminal clusters of rosy tubular flowers, each about three-quarters of an inch in length, the mouth of the tube being tipped with yellow. "Garten Zeitung," t. 840, pl. 2.

Fritillaria aurea.—A pretty little bulbous plant, about 5 inches in height, bearing a stem of four to six thick fleshy deep-green leaves, and a solitary nodding flower; the flower is pale-yellow in colour, spotted, or chequered with brown. It is a native of Silesia, and perfectly hardy. "Gartenflora," t. 840, pl. 1.

Ranunculus amplexicaulis.—A pretty white-flowered Crowfoot, a native of the European Alps, and well worth culture. The nerved glaucous leaves clasp the stem, like those of a *Rodanthe*, and the flowers are borne in terminal clusters, each being about the size of half-a-crown, pure white in colour, with a yellow tuft of stamens in the centre. It is sometimes grown as a pot-plant for spring flowering. "Gartenflora," t. 841, pl. 1.

Calochortus glaucus.—A very pretty little Californian bulbous plant, introduced by Mr. Elwes; it has a solitary, narrow lance-shaped leaf, and bears two or three flowers on a scape; the flowers are white, having a rosy blotch at the base of each hairy segment. "Gartenflora," t. 841, pl. 1.

Proteinophallus Rivieri.—This is the plant now well known to cultivators as *Amorphophallus Rivieri*, and is the hardiest in the group to which it belongs, and the only one which is valuable as an outdoor decorative plant. It was introduced to French gardens some years ago by M. Rivière, of the Luxembourg, and is a very effective decorative plant. We have seen it offered for sale as a pot plant in Covent Garden for the last two years. Like its allies, it throws up an umbrella-like head of deep green foliage, borne on a cylindrical stem, 2 to 3 feet in height. The spathe is 4 or 5 inches across, and of a livid purple colour, spotted with green below, the spadix being purple, streaked with white. It is well worth culture, either for indoor decorative purposes, or in the sub-tropical garden. It is figured in the "Botanical Magazine," t. 6, 195.

Ferula (Euryangium) Sumbul.—A valuable but fetid drug-producing plant, introduced to Kew from the Imperial Garden at Moscow in 1872, one of which bloomed in July last. It is a native of Turkestan, where it inhabits the mountains to the east of Samarkand, at an elevation of from 3,000 to 4,000 feet, where it was discovered by Fedtschenko in 1869. According to Flückiger and Hanbury's admirable work, the Sumbul plant is remarkable for the fetid, musky, and milky juice of its roots; it was introduced into Russia in 1835 as a substitute for Musk and as a remedy for cholera, thence it reached Germany in 1840, and England in 1850, where it was admitted into the Pharmacopœia in 1867. The root is imported in transverse slices, 1 to 5 inches in diameter, with a dry papery bark, resinous inner surface, and spongy farinaceous central portion, which has a musky odour and bitter aromatic taste. The plant closely resembles a *Ferula* in habit, and throws up a branched flower-stem, 8 or 10 feet in height. It belongs to the Umbelliferae, and its yellowish flowers were fertilised by bees, but, owing to the wet cold summer, the fruit did not ripen at Kew. "Botanical Magazine," t. 6, 196.

PICEA PARSONSIANA.

SOME doubts having been expressed in the American "Gardeners' Monthly" as to whether or not this is a variety of *P. grandis*, Mr. Parsons writes to that periodical as follows:—The seed from which this *Picea* was grown was received without name from California in the spring of 1853. In the autumn of 1855, Mr. Stuart Low, then in America, bought all the young plants which we were willing to spare. A plant was also sent to Kew Gardens and to Mr. Barron, at Elvaston. Some years after our plant was introduced, seed was received in England, the trees from which I saw, in the spring of 1859, in the grounds of Messrs. Waterer & Godfrey, at Knaphill. These I recognised at once as our *Picea*, although it was called *lasiocarpa*. We then wrote to Mr. Barron, who told us that the true *lasiocarpa* was totally different from the plants of Messrs. Waterer & Godfrey, that their plants were wrongly named, that our *Picea* was undoubtedly a new species unlike anything known in England in 1855, and that he should adhere to his nomenclature given at that time, which was *Picea Parsonsiانا*. On examining our own plants, as well as those of Messrs. Waterer & Godfrey, we found that the species sported very much, and produced trees widely differing, but having a predominance of straight leaves. Finding among our own stock a variety which we did not find in England, with curling leaves, symmetrical form, and a remarkable Fern-like aspect, we decided to propagate that only, and let the straight-leaved plants go. This curled form can be perpetuated only by grafting. From seed it sports as much as the Norway Spruce, and the curled variety cannot be so obtained with certainty. This variety having been cultivated as *lasiocarpa* by Messrs. Waterer & Godfrey, was distributed by them under that name. Mr. Bolander, formerly botanist of the California State Survey, on a recent visit to our grounds, examined our plants, and stated that they were all *grandis*, that the straight or flat leaf was the coast form, and the curled leaved variety, or our *P. Parsonsiانا*, was the mountain form. Mr. Fowler, of Castle Kennedy, says that *P. Lowii*, which he makes a synonym of *Parsonsiانا* and *lasiocarpa*, was discovered by Mr. Wm. Lobb in California, and that seed of it was sent home in 1860. If, therefore, *Lowii* and *Parsonsiانا* are identical, and if our plants were sent to Mr. Low in 1855, and this seed from California came in 1860, it is clear that we are entitled to the name, however unwilling we may be to interfere with the rights of Mr. Low, for whose personal character and enterprise we have the highest respect. Be that as it may, the tree remains, and no description can do justice to its beauty. It is worthy of admiration at all seasons; but, in June—when the new growth overspreads the old, when the delicate light steel-green of the new shoot is contrasted with the rich darkness of the old, and the leaves curl up over the branches till they almost meet—it is especially beautiful. My finest specimen, near my house, succumbed to the frosty weather of 1872. Lovers of trees would sit upon my piazza and, fascinated by its charms, gaze upon it as a connoisseur would upon a beautiful picture. Of all the disasters of that disastrous spring, none were more felt than the loss of this charming specimen.

Caution to Petroleum Consumers.—The recent deplorable loss of life and property by the burning of the Goliath should serve us a caution to all who use petroleum, in any of its many aliases of molucca oil, crystal oil, Alexandria oil, &c., not to burn it in metal containers. The evidence given at the inquest shows indisputably (coinciding with the result of our own experiments), that if the oil in the lamp when upset had not been raised considerably above 100°, Fah., it would not have taken fire from the flame of the wick. Now in a glass or earthenware container—both of which materials are bad conductors of heat—no such rise can occur, it being extremely difficult, and especially during the winter season, to raise the oil in it above 60° or 65°, at which temperature it cannot be made to take fire, either in bulk or when spread on a flat, boarded or tiled floor. But in the metal container used in the Goliath, when nearly empty (as it must have been after burning all night), not only is the oil easily raised to a high temperature, but a quantity of inflammable vapour is given off, which is far more dangerous than the oil itself. We have not the slightest doubt, from our own numerous experiments with petroleum in various lamps, that when used in glass or earthen containers with ordinary care, there is not the slightest danger of combustion beyond that required for illuminating purposes; but in numerous cases in which we have burned it in lamps without the intervention of a non-conductor between the flame and the container, vapour has been given off so abundantly as to take fire around the joint, whereas this accident has never occurred with the glass containers which we have constantly used during the last two and a half years, both with Hinks's Duplex and the Paragon burners. We have, therefore, no hesitation in cautioning our readers against the

use of metal for the purpose of holding petroleum in lamps, and still more in stoves; while, on the other hand, we can assure them as to the safety of glass when employed in lieu of metal. We do not know whether in the Goliath lamps the layer of cork generally employed by Mr. Hinks as a non-conductor was introduced; but, though this to a certain extent acts as a non-conductor, the layer is too thin to be a complete safeguard, according to our experience.—"Field."

Waterton's Filbert Tree.—Walton Hall had at one time its own Corn mill, and when that inconvenient necessity no longer existed the millstone was laid by in an orchard and forgotten. The diameter of this circular stone measured 5½ feet, while its depth averaged 7 inches throughout; its central opening had a diameter of 11 inches. Some bird or squirrel had dropped the fruit of a Filbert tree through this hole on to the earth, and in 1812 the seedling was seen rising up through the opening. As its trunk gradually grew through this aperture and increased, its power to raise the ponderous mass of stone was speculated upon by many. Would the Filbert tree die in the attempt? Would it burst the millstone? Or would it lift it? In the end the little Filbert tree lifted the millstone, and in 1863 wore it like a corinoline about its trunk, and Mr. Waterton used to sit upon it under the branches. For a representation of this stone and tree see p. 227, Vol. II.

Plants known to be Carnivorous Half a Century ago.—Within the past three or four years the subject of carnivorous plants has received a considerable amount of attention from men of science and others. It has been asserted that certain plants, such, for example, as the Sundew (*Drosera rotundifolia*), capture, dissolve, digest, and absorb flies and insects which are placed upon or happen to touch specified portions of them. The insects and flies are, it is stated, devoured in this manner for the purpose of supplying the plants with food. The attention, says a correspondent of the "Times," which this subject has excited, and the surprise expressed by many persons, led several to suppose that the utilisation of insects as food by *Drosera* was a new discovery. That it is not so, however, the following passage from "Coombe's Constitution of Man," printed in 1835, will show, Sec. 5, No. 6:—"Destructiveness is given, and man is constituted with a carnivorous stomach, and animals to be killed and eaten, exist. . . . Not only has Nature taught the spider to construct a web for the purpose of ensnaring flies, that it may devour them, and constituted beasts of prey with carnivorous teeth, but she has formed even plants, such as *Drosera*, to catch and kill flies and use them for food." Coombe probably copied from another writer, so in all probability the vagaries of carnivorous plants were known half a century ago, instead of the other day, as one would suppose, had he nothing else to judge from but the sudden demand for Sundew by hundreds of persons who desire to gratify a cruel curiosity in observing the wriggling agonies of an ant or fly placed upon its leaves.

NOTES AND QUESTIONS—VARIOUS.

Cork Tree Acorns.—Mr. John Jay Smith, of Germanstown, Philadelphia, U.S., writes to us stating that he wishes to make some experimental planting of the Cork Oak in the United States, and would be glad if any correspondent of THE GARDEN would inform him where he may obtain good seeds of it.

The Northern Spy as a Keeping Apple.—We hear a very good account of this fine Apple as a keeper in its native country, and of good specimens of it being eaten as late as the 19th of July. It would not be true to say that they were as good as they would have been three or four months earlier, but they were the best Apple that we ever ate so late in the season. They were not withered and nearly dried up, as is the case with Russets preserved in this way, but were fresh, crisp, juicy, and aromatic—real Apples, and not apologies for them.

The Jasminum nudiflorum against Light-coloured Walls.—At this time of year I am often compelled to admire the beauty of this naked-flowered *Jasminum*. The illustration of it (see p. 41) admirably depicts its floriferousness through the otherwise comparatively flowerless month of January. Cultivators should, however, discontinue planting it against walls or houses built of ordinary white or straw-coloured bricks, which are ill calculated to show off its bright yellow flowers to advantage. Red brick or any dark ground colour is best. This *Jasminum* ought to be found everywhere where hardy creepers are grown.—A. D.

Varietated Thyme Best for all Purposes.—It is a singular fact that the golden variegated form of the common Lemon Thyme is more robust than the green-leaved kind, in a circumstance somewhat unusual in the case of variegated plants. Apart from the beautiful character of the leafage of this Thyme, however, which renders it so attractive during spring and summer, it has the special merit of retaining its foliage all through the winter, and, in this respect, is much more useful for decorative purposes than the common variety. Indeed, looking at the beauty of its foliage and perennial character of the leaves of the Golden Thyme, it seems difficult to understand why the common kind should be grown at all.—D.

Abies Albertiana.—This is the Californian type of *Abies canadensis* or Hemlock Spruce; but it is greatly superior to the latter, being a more robust and rapid grower. It also retains the graceful drooping habit of the Hemlock Spruce, without that over-inclination to form a bush which the latter possesses. Its foliage, not only in the winter, but in the summer, is a more nearly indistinct green of the Hemlock. I have a number of plants of both kinds growing side by side in the nursery here, where the contrast between the two is strikingly apparent. I have no doubt that *Abies Albertiana* will prove to be one of our best drooping Conifers, as well as one of the largest and most ornamental of timber trees.—G. B., Longlat.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare*.

NEW ROOTS AND OLD VINES.

No fruit tree bears root-pruning better than the Vine, nor is there any fruit-bearing tree which better, or more quickly or generously, repays any attention that may be given it in the way of an improved border to feed in, or periodical top-dressings. If the roots wander too far afield, or if they get into an unwholesome or hungry sub-soil, they may be cut back without any hesitation, and brought near the surface in fresh soil, and will not suffer for it very perceptibly as regards the crop, provided an average amount of care is exercised in the work. This has been stated over and over again; but still there are some who hesitate to adopt strong radical measures with unproductive or retrograding Vines, from fear of disaster. Two years ago, a failing Vine, whose stem was introduced to the inside of a Vinery underneath a brick passage, about 6 feet wide, through a narrow brick drain, had to be lifted and re-planted. The roots were in an outside border, as usual, but on examining them, or it—there was but one—it was found to have struck deep down into the sub-soil. In the few feet of brick drain, however, it was found that a quantity of fibrous roots had pushed from the stem. The Vine was lifted, the drain roots preserved, but the thick root already alluded to was chopped off close to the end of the drain, and a curious old stump of a Vine plant it then was. It was re-planted, however, with the stem roots disentangled, in a border of good soil, and the result was a really fine crop of Grapes the same season. The Vines in a Muscat-house here, which were probably over fifty years old, were entirely lifted and re-planted in 1874, and, I am glad to say, without the loss of a crop. Indeed, the Grapes produced during the experiment were probably the best that the Vines had ripened for many years before. It became evident, as the work proceeded, that the roots of the Vines in question had not been disturbed since the day when they were first planted. They had wandered beyond the borders, and no fibrous roots could be found—only long black, brittle sticks, of the same thickness throughout, some of them down into the hard gravelly clay which formed the sub-soil of the border. They had been planted inside, and the roots were at liberty to pass through arches into the outside border. It was, therefore, determined in the spring of that year to excavate the whole of the inside border; and refill it with fresh soil, saving all the roots possible. It was soon found that there were not many to save, and that the few that were left were in a state of decay. The border, it could be seen, however, had at one time been full of roots. It was a matter of extreme difficulty to preserve the roots which still remained; the soil was picked clean out of the arches until the old stems were quite undetermined. The roots were cleaned, half the width of border was filled up, and the old roots were spread out as the soil was being wheeled in. As the buds began to burst into leaf in March, the half of the border left empty was filled up with leaves and litter mixed, which warmed the new border, and before midsummer fresh roots were laying hold of the soil in abundance, especially round the base of the old stems, where previously not a vestige of small root was to be seen; now the fresh soil promoted the growth of a whorl of strong roots, which ramified into the fresh turf in all directions. The following autumn it was resolved to excavate the whole of the outside border in the same way, while the crop of Grapes was hanging not yet ripe, and the foliage still green. The outside border was about 60 feet long and 16 feet wide; operations were commenced at one end by taking out a trench down to the sub-soil, for no drainage was found, none being necessary in this particular position. Two men, with forks, then proceeded cautiously to pick away the soil and disinter the roots, a work of much difficulty, owing to their being so brittle and twisted every few inches; as with the inside border, no fibrous roots were found within the width of the border; the

feeding roots were far beyond, underneath a gravel walk, and many of the roots were down in the dry clay below, into which no trouble was taken to follow them; on the contrary, they were cut off; such as were lifted were laid back along the front of the wall, and covered over with straw as the work proceeded; ultimately they were all shortened back to a length, equal to half the width of the border, more or less. The bottom of the border was finally levelled, a drain laid along the front, and 6 inches of burnt clay, from an old brick kiln, laid on by way of making a more healthy bed for the soil. A new border, 8 feet wide, was made of yellow loam, some fibrous peat, bones, and rotten horse manure, the roots being laid out carefully, as the soil was being wheeled in. About the first week in March, when the Vines had begun to show green leaves, the open half of the border outside was filled up with leaves, which threw a gentle mild heat into the newly-made border. It should be mentioned that the extremities of several of the old roots were marked by inserting sticks in the border, and on examination about midsummer these extremities were found to be each furnished with a tuft of young healthy roots ramifying into the new soil. Some anxiety was felt as to how the Vines would behave at the setting period; they were subjected to somewhat cool temperatures at night, and not pushed during the daytime; they were abundantly syringed, and the inside border watered at intervals, the result being that they set their fruit as well as in former years. After the first flush of growth they seemed to stand still for a few weeks, but ultimately started with renewed vigour; the fruit swelled up well and ripened to a fine yellow colour, and kept in good condition until Christmas. The foliage throughout the season never attained a large size; but the wood became strong and ripened to a fine clear straw colour. Several young rods, which were encouraged after the second growth started, soon reached the top of the rafters. There is now the satisfaction of knowing that the borders, outside and in, are full of young feeding roots quite under control, and that the Vines have the benefit of whatever mulching or watering the borders may get. A greatly improved crop is expected during the coming season from these old Vines, which are as stout as one's ankle from the soil to the glass, before branching, which each of them does, into three or four rods. No one, therefore, need fear to lift the roots of Vines entirely, however old they may be; and old Vines should never be discarded without much consideration.

W. D. C.

NEW CHRISTMAS ROSES.

HAVING been asked sundry questions as to the propagation of *Helleborus maximus* or major, I venture to answer them through your columns. Mr. M'Nab informed me that pieces of root would not succeed in heat; therefore I have never adopted that plan. Having been informed that large numbers had been lost by being propagated late in the autumn, I took warning, and have always kept to the season which has proved so entirely successful. There is no danger in dividing Christmas Roses in the ordinary way at any season, when the weather and soil are suitable; but cutting up the rhizomes is quite another matter. Possibly a year might be gained by doing this in spring, when there would be no fear of the pieces rotting, as they do in autumn; but would the eyes be as strong then as in July? The common Christmas Rose (*H. niger*) has no root-stock worth working with; the largest clump of it can be broken up by the hand, and when well shaken will crumble into plants, so to speak, every two or three leaves having true roots attached to them. This is not, however, the case with *Helleborus maximus*, which has not a shallow-spreading root-stock like that of *H. niger*, but one which gets hard and goes deep and requires a spade to cut it. No one can break up an old-established clump of this kind by means of his hands alone, and its unwieldy roots dislike confinement in pots. It is to be regretted that your correspondent, "Berks," did not allow his seedlings of *H. niger* to flower. More than once I have been taken in triumph to a patch of "seedlings," which, on examination, proved, to the owner's mortification, to be only the produce of small, starved portions of root, that had been left when the parent plant had been removed. Mr. Peter

Robertson has tried crossing *H. maximus* with *Olympicus* and *niger*, but without any good result. *H. maximus* may be but a variety of the common Christmas Rose, but wiser heads than mine believe it to be a species. Neither in England, nor in the south of Scotland, have I ever seen this plant, equal either in colour of leaf or growth, to what I have seen it in Aberdeenshire. Those to whom this Christmas Rose was new were delighted with the fine clumps of it which they saw about Aberdeen; and, truly, in out-of-the-way gardens there, judging by the foliage, it might easily have been mistaken for a Peony. Leaving *H. maximus*, I want to elicit information respecting *H. angustifolius*, which, if my plant is true to name, has large white flowers, tinged on the back with rose. It is a most desirable variety, and one which, owing to the time at which it flowers, is more useful even than *H. maximus*, coming in, as it does, at least two months later than that kind, and with me a little earlier than *H. niger*. 'That it is a strong grower is proved by our reserve beds of it having been taken by a good judge of Christmas Roses for those of *H. maximus*. In another part of the garden, however, where the two kinds grow side by side, *H. angustifolius* could never be mistaken for either *H. maximus* or *niger*. Mr. M'Nab told me the other day that there is a major variety of *H. niger*, distinct from *H. maximus*; and certainly our *H. angustifolius* would suit such a name. Its flower-stalks, which bear two and three flowers on a stalk, are comparatively tall and stout, a great advantage as regards keeping the blossoms clean and convenient for cutting. It is a very free flowerer, and it ripens its seed. Believing that no variety of *H. niger* would seed here, we cut weekly, last winter, all the flowers off our border of *H. angustifolius* for an hospital, and one expanded bloom of it made a good centre for little bunches of Thyme and Rosemary, which are favourites in such places. On breaking up the border in June we found a single stalk that had been overlooked furnished with a promising seed-vessel. The plant which produced it was at once re-planted in a south border, and on the 15th of July the seed-vessel burst, and twelve good seeds fell out, which were sown then and there in a pot, and set in a cold frame, the result of which I am patiently waiting to see. This particular Hellebore I got five years ago from Mr. Anderson Henry. I was attracted by its tall growth and fine flowers. I saw, by its stature, that with liberal treatment and care it would succeed with us, and I have not been mistaken. Its rhizomes are like those of *H. niger*, but it is distinct from both that and *H. maximus*. F. J. HORS.

Wardie Lodge, Edinburgh.

PRESERVING CUT FLOWERS IN WINTER.

WHERE cut flowers have all or nearly all to be procured from under glass, as they have to be in winter, a both extensive and well-selected stock is needed to meet the various demands made upon it, one of the greatest of which is that for flowers with which to decorate churches, more especially at Christmas. In reference to this, I have lately made some observations respecting the relative duration of cut flowers in the cool, moist air and subdued light of such situations, and of those exposed in the dry air and strong artificial light to which they are subjected in reception rooms. The majority of cut flowers used for church decoration here were *Eucharis amzonica*, white *Camellias* and *Primulas*, and the scarlet *Poinsettia*. Of these, some were arranged in tubes of water and some in beds of damp Moss, and after the lapse of a fortnight they were, for the most part, found to be quite fresh, whereas the same varieties used in drawing-room stands needed replenishing several times during that period. In order to obviate the great waste that occurs in floral decoration, various expedients have been resorted to, such as using different kinds of water, the addition of chemicals, &c.; but the only real remedy is a cool atmosphere, and the removal of stands from the immediate neighbourhood of fire-places and lamps; for I find that, on account of its dryness, the heat from these is more destructive to flowers than the greatest heat of summer. Those, therefore, who do not possess large reserves of flowers with which to replenish their vases will do well to make their floral displays in the coolest positions possible, removing the stands,

when not in use, to a cool cellar or some such situation. It is also indispensable, for the economical arrangement of flowers, to have vases of various sizes; for, while many of the most useful flowers cannot be procured with stalks long enough for deep vases without greatly disfiguring the plants from which they are cut, they may be made to look very effective in flat decorations. For this purpose, I find nothing better than glass baskets about 6 inches in diameter, a size serviceable both for dinner table and drawing-room. For edgings, I am by no means in favour of always using Fern fronds, for even where the choicest varieties are employed for that purpose they become monotonous when constantly repeated. I like stands in which Roses predominate to be edged with Rose leaves; while, in the case of Geraniums, I would edge with the Oak and scented-leaved varieties, as nothing, in my opinion, adds more to the beauty of a flower than surrounding it with its own foliage. As regards the height desirable for vases, all depends on the size of the apartment in which they are to be placed. We use trumpet-shaped vases 6 feet high, filled with the largest spikes of Cannas, *Hedychiums*, &c., and, by the side of large mirrors, or in lofty entrance halls, vases of this description produce an excellent effect; but in small rooms, or when filled with small flowers or foliage, their appearance is by no means pleasing. The best effects are most readily obtained by the use of moderate-sized vases, as the material for furnishing them properly is much more varied. Highly-coloured or figured vases are objectionable, inasmuch as both colours and figures detract from the effect. For the arrangement of cut flowers no specific rules can be laid down; but it may be well to bear in mind that the more nearly the flowers are placed in the positions in which they grow naturally, the better will be the results. Sprays of climbing or trailing plants should hang gracefully over the edges of the vases, for when reversed, as is sometimes seen in flat decorations, the effect is stiff, formal, and unnatural.

Henham Gardens.

J. GROOM.

Barham's Worm-proof Pot Drainer.—This is an invention sent to us by Messrs. Dick Radcliffe & Co., for preventing the entrance of worms into pots, and one which has been found to be very effectual for that purpose. It consists of a square piece of perforated zinc, the outer side of which has a jagged surface, and that being placed downwards over the hole in the bottom of the pot, effectually prevents the ingress of worms, while it does not prevent their egress should they happen to get in among the soil. As a drainer, too, it cannot fail to be efficient.

Hyacinthus candicans.—This remarkable species of a well-known genus proves to be a most ornamental cool greenhouse or border plant, for it is so accommodating as to be equally suitable for both places. It forms a large bulb of about the size of the common Hyacinth, from which are produced several long strap-shaped leaves, from the middle of which is thrown up the flower spike. This is from 2 to 2½ feet in height, or even more under glass, and bears on its upper half from twenty to thirty large, bell-like flowers, of a creamy-white colour, on drooping foot-stalks. It is a plant of easy cultivation, and may be raised from seeds with facility, but the young plants will not flower until the fourth year. The full-sized bulbs being at present somewhat high priced, seeds offer an economical means of obtaining a stock. It is a native of the Cape of Good Hope.—W. THOMPSON, Ipswich.

Carnations in Window Boxes.—Anyone who is familiar with the south of Europe must recollect with pleasure the beauty of the boxes of Carnations which deck the windows of the houses, hanging down loaded with heavy flowers. I do not recollect to have seen Carnations grown on window-sills in this country; but I intend to try them this year. They naturally prefer walls and dry places, and everything they require can be supplied more easily in boxes than in beds, such as drainage, sunlight, free air, &c.—SALICORNERS.

Poinsettia as a Table Plant.—The simplest and most effective floral ornament for the centre of a dinner-table that I have seen for some time consisted of a few well-grown and dwarf plants of *Poinsettia pulcherrima* grouped in a low vase. This bright colour so effectively, by artificial light, the relief afforded by the ample green leaves, and the dwarfness of the plants, allowing a free view across the table, are advantages which make it the prettiest single plant obtainable for the purpose at this season.—B.

Dead Vine Roots.—The Vine roots sent by "Tyro," show no appearance of *Phylloxera*. But a more complete account of the circumstances under which their decay has taken place, would be necessary to enable us to give an opinion as to the cause of their death.—A. M.

NOTES OF THE WEEK.

— THE American Squashes have at last appeared in Covent Garden, and are obtainable at Mr. Lehan's. The kinds are the famous Hubbard and Turban, both raised by Mr. J. H. Gregory, of Marblehead, Mass., by whom the consignments now in the London market have been sent.

— PEARS have not been so well flavoured this season as usual, doubtless through want of sunshine in autumn. *Ne Plus Meuris* forms, however, one exception to this rule. It is at all times a good late Pear, but this season it is unusually excellent.

— AMONG specimen Orchids shown at South Kensington, on Wednesday last, was a remarkable Australian *Dendrobie*, having curious slender white petals and a curled lip. This proved to be the old *D. teretifolium* which bloomed thirty years ago in Loddige's collection, at Haecney. Sir W. Marriott, of Down House, Blandford, sent a splendid specimen of *Cattleya bulbosa*, on a block, bearing fifteen fully expanded flowers; and a specimen, with ten flowers on it, of the new golden-flowered *Masdevallia Davisi*, came from Mr. Burnley Hume's collection, at Winterton.

— CAPTAIN RAIKES, of the Floral Depot, Baker Street, sends us a beautiful example of a new kind of bouquet which he proposes to introduce, and which he names the Fan Bouquet. It is formed like a fan, with satin platings on one side and a bouquet on the other. Captain Raikes considers this more convenient for opera bouquets, &c., than the old form in which the flowers were injured when the bouquet was laid down. The fan bouquet may not supersede the old form for ordinary use, but it will prove more convenient for certain purposes. It may be made in a variety of tasteful forms, and is a desirable innovation on the time-worn way of making bouquets.

— *ABIES EXCELSA AUREA*, a distinctly golden-tinged variety of Fir, should be added to our at present somewhat short list of variegated Conifers. We recently saw some healthy plants of it in Messrs. Lee's nursery, at Feltham, where, contrasted with green-leaved plants, its yellow hue was set off to advantage. Indeed, the great value of these golden Conifers, *Aucubas*, *Hollies*, and similar evergreens, consists in contrasting them with masses of dark-foliaged trees and shrubs for winter effect. This variety was exhibited, and received a first-class certificate at South Kensington, last year.

— In the fine collection of Orchids at Whitechurch Rectory, Edgeware, belonging to the Rev. J. B. Norman, there are some very choice varieties of *Lycaste Skinneri* now in flower; amongst others, two fine plants of *L. S. alba*, with five blooms, also some fine varieties of *Odontoglossum Alexandr.*, *Hallii*, *radiatum*, and *Andersoni*; *Masdevallia polystricta*, with twenty spikes, *M. elephanticipes*, and choice varieties of *M. Veitchii*. A fine plant of *Cologny cristata*, purchased at the Manley Hall sale, is showing over 200 spikes of bloom. This collection, although it has been got together in about three years, contains some of the finest plants that have been in the market during that time.

— FROM a report furnished by Prof. Beal, of Michigan Agricultural College, it appears that experiments have been made on the grounds of the college with a large number of new and old varieties of Onions. From these experiments, Prof. B. recommends as most valuable the Red Wethersfield and Early Red Globe, for red Onions; although not quite so good in quality as the yellow and white varieties, they yield and keep well, and are rather more hardy. For yellow Onions, the Yellow Danvers and Improved Large Yellow are best. The white sorts are most delicate, and need careful banding; the best are White Globe and White Portugal. The Giant Rocca, Southport, Late Globe, and Giant Madeira, were large and productive, but did not ripen.

— LARGE tracts of land in the south of France, not hitherto cultivated, are being planted with the kind of Oak trees beneath which Truffles are generally found, and it is expected that each acre of this land, lately sold as low as £5, will yield a crop of Truffles worth £20 per year. The experiment has been tried in the department of the Vaucluse, and in the course of the last twenty years, 150,000 acres, which were absolutely unproductive, have been planted, and are yielding a rich return. The cost of plantation, which is borne by the Commune, does not exceed 17s. per acre on hilly ground, and though rather greater in the lowlands, the crops are proportionately heavier. Acres only are planted on the hilly ground, but saplings of five or six years' growth, placed in rows about 40 feet apart, are found to answer best in the lowlands. The ground between the rows is planted with Vines, which, after five or six years, repay the cost of the plantation and its culture.

— THE "St. James's Magazine," for February, will contain an article on the Royal Horticultural Society, by Mr. W. A. Lindsay, who was for two years its secretary.

LONDON PARKS AND TREES.

ARBORICULTURE in London has, no doubt, made some progress during the last few years, but anyone who walks about London with his eyes open may still constantly see such instances of neglect in the arrangement of trees, and even of sheer waste of public money, as to make him doubt whether those in authority over the parks can have any practical knowledge of the subject whatever. As an instance of this neglect I cannot forbear calling attention to the state of the row of trees, alternate Planes and Elms, in the Green Park, alongside Piccadilly. The Planes were, I suppose, planted about fifteen years ago, with the idea of superseding the Elms, which are, as is usual with all young Elms in London, of very stunted growth. They (the Planes) have grown well, but have been suffering for some years from close contiguity of the Elms. Anyone may see that something ought to be done in this case, but it looks to me as if those in authority meant to wait till both Planes and Elms were spoilt before they made their choice between them. As an instance of sad waste of public money, I will name (what I deprecate many others noticed at the time) the absurd and most unsuitable selection of trees planted some years ago on the rockery at the lower end of the Serpentine. I have often thought that I should like to have seen the bill for the Pinuses, Thujas, and other trees of the same nature which were then planted only to die, and of which I do not think one could now be found. "W. R.," in last week's GARDEN (see p. 70), takes a very hopeful view of what may be done with trees in London, but even he shows evergreens of almost every kind. I should venture to think that many of the trees which he names as doing well in London have grown up into large trees before London had become what it is now, and that newly-planted ones of the same variety will not thrive. With regard to Hawthorns of various kinds, the planting of which "W. R." advocates so much in London, I should be quite inclined to agree with him if it were not for the plague of caterpillars that infest them about the end of June every year in London, rendering them, for a great part of the summer, most unsightly objects. I shall be glad if any of your readers can give any information as to this insect pest, which seems to abound in London, and which is hardly to be found in the country. F. S.

Ricinus Gibsoni and its Culture.—Now that the season is at hand for procuring a stock of seeds for the sub-tropical and flower gardens, I venture to recommend this *Castor-oil* plant as the finest and most useful that has been introduced for many years. Associated with Mangles's *Geranium* or *Lady Plymouth*, it makes a fine bed and one which breaks up that flat appearance which is too common in flower gardens. It is quite distinct from everything else, and its free outline and quick growth are not the least of its recommendations. In cultivating it I should sow the seed in February or not later than March, in a gentle bottom-heat putting one seed in a small pot; when they come up and the young plants have filled the pots with roots they should be potted into 7 or 8-inch pots in a good rich compost, and should be kept in some warm house; a Vinery at work suits them perfectly, provided they can be kept near the light. If it is necessary to keep the plants dwarf they may be stopped after they have made two or three leaves; in May they should be gradually inured to the open air, and by the end of the month they may be planted where they are intended to grow during the summer.—W. O., *Foto.*

Spring Flowers and their Colours.—Some interesting observations on the flowering of spring plants were made, the other evening, at a meeting of the Edinburgh Botanical Society, by Mr. Buchan, who, with a view of discovering what lessons may be learned from the budding, leafing, and flowering of plants and trees, has collected much curious information on the subject. It appears from the result of noting the average dates of flowering of thirty-two species in the Royal Botanic Gardens during twenty-six years that the six latest springs were—1855, when the flowering was thirty days later than the average; 1870, when flowering was sixteen days; 1853, fourteen days; 1856, thirteen days; 1857 and 1865, each twelve days later. The five earliest springs were—1874, when flowering was twenty-three days earlier than the average date; 1869, when it was nineteen days; 1851, thirteen days; and 1858 and 1866, each eleven days earlier. The two extremes show a difference between the dates of flowering in different years of fifty-three days. The longest deviations from the average were before the equinox. As to the relations which these effects have to temperature, it was found that the mean temperature of Edinburgh fell to its lowest on the 11th of January, when it was 34°-8, and from this point it may be assumed that meteorological conditions commence which result in giving vegetation a start. Another question of great interest is the relation of the colour of flowers to their date of flowering. Taking 909 species of British flowers, 257 were found to have white flowers, 238 yellow, 144 red,

94 purple, 87 blue, the remainder being green and other colours. Of the blue flowers, 16 per cent. bloomed in April; 14 per cent. of the white flower bloomed only in that month, but only 9 per cent. of the reds, the yellows being very close to the latter. It thus appeared that the blues were far ahead of the reds and yellows, the whites being intermediate, and the purples and greens came in between the blues and the reds. This indicates the existence of some general law which arranges the flowering of plants in the British flora according to the colours in the spectrum.

Ivy and Trees.—Most practical men, who have had any experience in woodcraft will, I think, endorse Mr. Berry's statement upon this subject (see p. 50). If Ivy is allowed to grow unchecked, it has, I believe, pretty much the same effect upon trees everywhere; but, in some districts it will be found more difficult to keep within bounds than in others. In some woods, I have known even the ground under the trees to be carpeted with it, and every tree trunk, if not periodically cleared, would soon be covered with it. I have generally found it to make the most rapid growth on porous, well-drained soils. On rough barked trees, such as Oak, Elm, and Walnut, it makes, if unchecked, rapid progress, quickly occupying not only the trunk but also the main branches, until at last the only signs of life to be seen in the supporting trees are in the extremities of the branches. I admit that a wood, in which the trees are draped with Ivy, has a picturesque effect, and that on every estate, for the sake of this alone, a few trees might be given up to it; but, as your correspondent remarks, where timber is grown for profit, it should be cleared of Ivy.—E. HOBDAV, *Ramsey Abbey*.

An Open-air Ice-house.—Ice may be stacked in the open air in such a manner as will preserve it for nine or ten months, or even longer. After we have filled our ice-house, our plan is to make two large stacks in a valley overhung with spreading trees, but not immediately over the stacks. At the bottom of the slope (a north-east one, and one which is rather steep, thus affording ample drainage) we commence our stacks, and build "up hill" about 15 feet from the edge of the cartway—which has been made for the occasion. Some hurdles are placed at the bottom, forming a kind of semicircle, to prevent the ice when "tipped up" at the top from overshooting its bounds at the bottom. The ice, then, as in an ice-house, is well broken and rammed together, and boiling water is applied as the work proceeds to consolidate it. When the stack is headed, a man, with a ladder placed against it, rides in hand, commences at the top, and trims the whole stack right round to the bottom, thus filling all the crevices with the descending "ice dust," which is well beaten in as the operator progresses with his work. This done, the whole is covered with sifted sawdust 3 inches thick, then 2 feet thick of leaves, over which some long litter is placed to prevent the wind from blowing the leaves off; and, as a "finishing touch," the stacks, or ricks, are enclosed by hurdles which are fastened by tar twine to stout sticks driven into the ground, by which means cattle are kept off. I have seen many ways of preserving ice out-of-doors, but never have I seen any to answer so admirably in every respect as the one just described.—H. W. WARD.

Birds in the Botanic Gardens, Regent's Park.—Some time ago, when I sent to you a list of the birds seen by me in the Botanic Gardens, Regent's Park—which comprised several kinds, one could hardly expect to see there such as the goldfinch, kingfisher, siskin, and tree-creeper—I made this remark that I had not been able to meet with the bullfinch myself, although I had heard from one of the officials there that he had some years ago not only seen, but captured one. This winter, however, I have seen one several times. I first heard the note distinctly, and, feeling sure that it was not an imitation, as it was very early in the morning and no one was about, I crept quietly to the point whence I heard the note, and saw a fine cock bullfinch in good plumage. I have seen him several times since, and one of the gardeners tells me he has seen a pair—a cock and hen—but I have only seen the former myself. I may now mention that, since the late mild weather, the birds have been singing magnificently every morning in the Botanic Gardens soon after daybreak; in fact, there has been a complete chorus of the birds which sing in the warm days of winter—thrushes innumerable and robins abundant, with occasionally the clear pleasing note of the hedge sparrow and the merry double note of the titmouse; and, amidst all this tumult, could be heard on several occasions the deep, broken, yet not unpleasant notes of the mistleto thrush. It was curious to notice how little effect a sudden great lowering of the temperature has upon the notes of these birds. For instance, on one Sunday morning lately, the temperature was 31°, with a severe hard frost, but the air was calm; nevertheless the birds were singing as well as they did on the morning before, when the temperature at 8 a.m. was 45°. If, however, the low temperature lasts for any time, the birds cease singing; moreover, if there is any wind with a low temperature, they are silent.—HENRY SMITH, in "Field."

THE PAMPAS GRASS AT LONGLEAT.

This succeeds well here, and is planted out in the wild ornamental coverts rather extensively, chiefly in groups of three, five, or more plants, in proportion to the extent of their surroundings. Single specimens, possessing distinct colours and uncommon forms, are planted in suitable nooks, where space is more limited, and also in groups here and there, for the sake of contrast; but the best effects from Pampas Grass are obtained by forming clumps, or groups, on slightly-raised mounds in front of masses of Rhododendrons, Lanelas, or other dark-foliaged shrubs of large growth. Of the different varieties, the upright silvery kind is the most striking, and the one which retains its beauty for a much longer period than any other. The drooping form of plume is handsome; but, unless it be supported by means of stakes and string, numbers of them get broken down by the wind before the whole of the panicles are fully developed; for this reason, this particular variety should be planted in the most sheltered positions, and not exposed to cutting winds, but at the same time it should have a dry airy site on a porous sub-soil, and should be planted on raised mounds like the others. The Pampas Grass is rarely cut down here by severe frosts; it should, however, be slightly protected before winter sets in by tying up the foliage in the shape of a cone, with a Willow band or tar-cord; this helps to prevent snow and rain from settling down into the crown of the plant, an evil from which so many throughout the country perish; a kind of rot is induced by the hearts being alternately wet and frozen. A few Fir branches, stuck in round each plant, serves to protect it from ground game. In planting Pampas Grass, the soil should be well trenched to a depth of 15 or 18 inches, and about a cartload of road parings, road drift or fibry turf should be given to each plant; a heavy mulching of manure should also be spread on the surface after planting, the manure being covered with Bracken or Fir branches to prevent game from scratching it away, and to render it less objectionable to the sight. After the plants have become established they will derive great benefit from a covering of leaf mould being spread over the surface around each plant, or group of plants, every autumn. GEORGE BERRY.

Tom Put Apple.—Mr. Scott states (see p. 50) that the Apple which I described (see p. 27) differs from the true Tom Put; but I see no reason to alter the opinion which I expressed respecting it. Tom Put is as well known in this district as any sort grown. Mr. Ellacombe is right in saying that it is not a good keeper; for I find that it only keeps well until Christmas, when it becomes moist and sticky in handling, and has a bruised appearance, many being soft or "sleepy." Mr. Scott states that my description of Tom Put refers to an Apple known in Somerset as the Colebrooke, which he says closely resembles Hoary Morning. The latter is known here by the name of Sour Woodbine; but in North Devon as Hoary Morning. It is quite distinct from Tom Put, both in fruit, fruitfulness, and habit of growth. A good-sized tree of it here, about forty years old, bears, as a rule, well every alternate year. Two trees, headed down and grafted with it where they stood in the orchard ten or twelve years ago, are growing well, and have made new heads 15 or 20 feet through; but have never borne a bushel of Apples since they were grafted, whereas Tom Put always bears well, and therefore grows slowly. Hoary Morning keeps well up to Lady-day, and is a handsome good carnation-striped culinary Apple, which, when gathered, is covered with a beautiful bloom equal to that found on some Plums.—JOHN GARLAND, *Killerton, Exeter*.

Gladiolus Cooperi.—A very curious species, reminding one of *G. dracocephalus* in form, but brighter in colour. It is a native of Natal and the Cape; the flowers are yellow, profusely streaked with red, the lower divisions being nearly pure yellow. Although scarcely so attractive as *G. Saundersii*, *G. cruentus*, and one or two others, it is nevertheless well worth culture, and, as Dr. Hooker remarks, the advent of these new forms enlarges "materially the groundwork upon which hybridisers can carry forward their experiments." The present plant was found by Mr. Thos. Cooper, when collecting for Mr. Wilson Saunders. "Botanical Magazine," t. 6, 202.

Ross Nonpareil.—This is at present one of our best dessert Apples. It grows well and forms a handsome orchard tree, which bears freely every year. It also succeeds as a small pyramid or bush tree. I have been told that there are two varieties of this Apple, one very inferior to the other, but it is the best sort to which I have just alluded.—J. G.

Northern Spy Apple.—I bought a young tree of this some years ago, took grafts from it, headed down a healthy young tree in the orchard and grafted it with the Northern Spy; the grafts grew freely, but never bore an Apple. Last spring I headed it down and re-grafted it with another sort; the tree which I bought grows freely, but has never borne more than four or five Apples in one year. They are very handsome, and keep well, but the tree is too shy a bearer to be worth growing.—JOHN GARLAND, *Killerton, Exeter*.

THE FLOWER GARDEN.

ROOT-WORK.

My experience of root-work is less unfavourable than that of your correspondent (see p. 32). In 1871, the only root-work which I had seen was one small one, which had a pretty effect, and which appeared to agree with the plants grown on it. Having a north bank near the house to be made ornamental, I consulted a gardening friend, who had considerable knowledge of root-work and also good taste. He helped me to put up a root-work bank, which, with its curves, was about 100 feet long, and about 10 feet high at its highest point; and there was also a long mound about 40 feet long by 10 feet wide. While these were being proceeded with, I had the means of consulting the very highest authorities, both scientific and practical. About half spoke of root-work as your correspondents write of it; the other half thought very well of it. I took the hopeful view myself, but thought it only prudent to put up a quantity of brick burr-work, and afterwards of sandstone rock-work. I have therefore had the means of comparison. I do not think *Cyclamen* could look as beautiful in rock-work as they do in root-work. *Cyclamen vernum*, blooming in its bay, in contrast with the dark wood, makes a picture which would have been more than once taken had not the flowering-time been during such cold weather. *Cyclamen hederacifolium*, whose beautiful leaves crowd up to its recess, flourishes so that a few days back I took away from it sixty seed-bullets with a leaf to them. *Trillium grandiflorum*, *Epimediums*, &c., half-way up, thrive well; but I think in the upper parts, dwarf shrubs, such as *Skimmia japonica* and *obolata*, *Pernettya*, *Azalea mollis*, *Sedums*, very dwarf *Rhododendrons* and *Retinoparas*, *Andromedas*, *Spirea palmata*, *Menziesias*, &c., together with strong creepers, such as *Waldsteinias*, *Arenaria grandiflora*, *Acanas*, *Lithospermums*, *Fragarias*, &c., all have the best effect; *Campanulas*, large and small, do well. In the lower caves, *Hepaticas* thrive thoroughly. Slugs are troublesome, but not so much so as in the burr bed. I have read that in some places where peat cannot be had, *Heath* plants are grown in rotten wood. *Gaultheria procumbens* is in absolute perfection and beautiful—first, as regards its bell-shaped blossoms, and afterwards its berries—the roots creeping between the bark and wood; *Linnaea borealis*, too, would I think vote for wood rather than rock. If the roots are well embedded in the soil, no serious slips, I think, are likely to take place. What I most dreaded was the tendency to foster "evil-smelling fungi," but these appear to be under control. The beautiful shades of green of the different Mosses that in many places clothe the wood and soil greatly add to the beauty of my root-work, which work was noticed in THE GARDEN, Vol. V., pages 323 and 345, when it was thought to be "a pretty object."

Heatherbank, Weybridge.

GEORGE F. WILSON.

New Hardy Begonia (*Begonia Frœbelii*).—This distinct and beautiful *Begonia*, to which I have before alluded (see p. 543, Vol. VIII.), deserves additional attention on the part of cultivators and hybridisers, inasmuch as it is sufficiently hardy to be cultivated on sheltered portions of rock gardens in favourable localities. A month or two ago I saw a plant of it in one of the greenhouses at Chiswick, and was struck by its distinct habit of growth, all the leaves being radical, and by the profusion with which its large panicles of crimson-scarlet flowers were produced. At Cologne, I am informed, it has been used with success as a bedding plant, and there seems every reason to believe that, by forming prepared beds of peat,

turfy loam, and leaf mould, we might even, in this country, use not only this, but many of the new hybrid forms of B. Veitchii, B. Clarkii, B. Boliviensis, &c., in our flower gardens and on sheltered rock-work.—B.

***Lilium nepalense*.**—I was glad to hear from Mr. Barr that he has just received a few bulbs of the only true Lily still known in India which has never been introduced, viz., *Lilium nepalense*. This plant, which is allied to those magnificent species *L. Wallichianum* and *Neilgherriense*, is figured only in Wallich's "Plantæ Asiaticæ Rariores," and, as far as I know, has never been in Europe before. The bulbs, which were in good condition, are small and pear-shaped. From the account given by Mr. Barr's correspondent, the plant will be as hardy if not more so than *L. Wallichianum*, which remained green in my garden until December. There are only two Lilies now wanting of which we have any certain knowledge, viz., *L. avenacum* and *L. medeoloides*, both of which are natives of the coasts and islands of north-eastern Asia.—H. J. ELWES.

Species of Tulip.—In the notes on new plants in last week's GARDEN (see p. 47), *Tulipa Eicheri* is mentioned as having been introduced by me. This is not quite the case, as though I believe I was the first to flower it in England, I had nothing to do with its introduction. My bulbs came from Dr. Regel, of St. Petersburg, and from my friend, Herr Leichtlin, of Carlsruhe. I rather fancy that the plant was introduced by Messrs. Haage & Schmidt, of Erfurt, under the name of *Tulipa Julia*, but am not sure of this. I am glad to say that the firm in question have re-introduced, among other varieties, the pretty and peculiar-looking little *Tulipa biflora*, a Russian species which has been lost or unheard of for many years. Let us hope that other bulbs from the same country, such as *Rhinopetalum Karelini*, recently figured in the "Flora des Serres," Korolkowia, Severtzowii, &c., may soon follow.—H. J. ELWES.

Begonia Frœbelii.

Rose Captain Christy.—This is the beginning of quite a new type of Rose, and its whole habit clearly indicates its being, without doubt, a hybrid Tea. It is an evergreen, and it blooms much more beautifully and in better form under glass than out of doors in this country. It becomes delicate late in autumn out of doors, and will not live on the Manetti stock. "Captain Christy," says the "Floral Magazine," "was almost the first Rose in bloom out of doors with Mr. Bennett at Stapleford in the spring; it continued to flower all through the summer, and was particularly fine in the middle of November last. The fact of this Rose being a hybrid Tea quite upsets the theory entertained by many Rose-growers that the Tea Rose will not blend with the hybrid Perpetual. Captain Christy was originally raised by M. Lacharme, a grower who has perhaps produced more really good Roses than all the rest of the raisers put together; and we have his authority for stating it to be a true hybrid between Victor Verdier fertilised by the Tea Rose Safrano. 'Here is a sketch,' says M. Lacharme, in a letter to Mr. Bennett, 'of my seed-bearing Roses, planted against a wall and facing the south. The first flowering is from the 15th of April to the 13th of May, and is useless for seed, for the flowers are very full, little disposed to bear reproductive organs, and still less adapted for fecundation. It is necessary to restrain this first blooming, so as to arrive as soon as possible at the second flowering, which commences at the end of June. This latter blooming is the best for fertilisation, for now the flowers are less full, the reproductive organs are more fully developed, and the fine dew of summer is a great aid to fecundation. Some growers practise artificial fertilisation, but I have little faith in it. It is necessary that the specimens to be hybridised should be from ten to twenty years old to produce really good new kinds.'"

The Line of Greatest Danger from Frost.—A correspondent of the "Gardeners' Chronicle," says that it is not sufficiently known that a thermometer placed 1 foot from the ground reads lower than one at 4 feet high. By calling attention to the fact, it may, perhaps, warn us to provide shelter accordingly for all very dwarf-growing subjects. It may be serviceable, too, perhaps, to note that it is low-growing subjects from 12 inches downwards that suffer the most

from a severe frost. From observations made in 1860 and 1871 the frost line appears to reach its maximum from 8 to 14 inches from the ground.

GARDEN VEGETATION IN DECEMBER.

By JAMES McNAB, Royal Botanic Gardens, Edinburgh.

DURING the early part of December the weather was very changeable, and we had a good deal of frost, snow, and rain. On the 5th snow laid on the ground to a depth of 6 inches; it remained about a week, when it suddenly disappeared, and after that high winds and rain prevailed until the end of the month; on twelve days only was the thermometer at or below the freezing point, indicating collectively 31^o—of this number 75^o were experienced during the first fifteen days, while 6^o only were registered between the 15th and the end of the month. During December, 1874, the thermometer was on twenty-eight mornings at or below the freezing point, indicating collectively 277^o of frost, 19^o occurring during the first fifteen days, and 198^o between the 15th and the end of the month. The six lowest temperatures experienced during December, 1875, were on the mornings of the 1st, 3rd, 4th, 5th, 7th, and 15th, indicating respectively 22^o, 25^o, 25^o, 22^o, 24^o, and 23^o, while the six highest morning temperatures were on the 13th, 14th, 26th, 27th, 30th, and 31st, when 39^o, 39^o, 40^o, 43^o, 43^o, and 44^o were indicated. The following table shows the amount of frost during December, for the last thirteen years:

1863 . 50 ^o	1867 . 41 ^o	1870 . 120 ^o	1873 . 36 ^o
1864 . 75 ^o	1868 . 22 ^o	1871 . 59 ^o	1874 . 277 ^o
1865 . 16 ^o	1869 . 119 ^o	1872 . 54 ^o	1875 . 51 ^o
1866 . 31 ^o			

A table, compiled from a series of notes made on garden vegetation, during the year 1875, shows that 658 species and varieties of Alpine and dwarf herbaceous plants have flowered on the rock-garden during the past twelve months. The numbers just given are considerably below those of species cultivated on it, but it gives a fair idea of the proportion of Alpine plants that flowered during each of the last twelve months. This list, however, does not include a number of dwarf Alpine shrubby species, which do not flower regularly, nor many species of plants which do flower, chiefly belonging to the genus *Saxifraga*, *Sempervivum*, and *Sedum*. These, however, will be given in a third table presently. The following table shows the number of species as they came into bloom during the year:

Jan. 13	May 162	Sept. 15
Feb. 18	June 140	Oct. 3
March 55	July 73	Nov. 1
April 123	Aug. 49	Dec. 6

The above table shows a rise in the number of species as they came into flower during each month up to May, after which, as will be seen, they begin to fall off. On the 15th and 16th of May twenty-one species are recorded as having flowered, which is more than did so during any other two consecutive days throughout the year. With ordinary cultivated border herbaceous plants the largest number of species is generally to be found in bloom during June and July. Besides the general list given of Alpine plants flowering during each month, and made up from daily observations, a list has also been kept showing the duration of blooming of many plants. In some cases it has been found that certain species remained in flower for one, two, or more weeks, while others continued in a blooming condition for two or three months successively. Five species, however, were observed to be in a flowering state for four, five, or more months together, such as the *Veronica rupestris*, *Lithospermum fruticosum*, *Androsace lanuginosa*, *Bellis rotundifolia*, and *Linaria alpina*. Of these, the first has been in flower in one place or another of the rock-garden during every month of 1875, and the *Lithospermum fruticosum* since the 13th of April. During the month of December the following additional species have come into bloom, viz., *Helleborus orientalis*, *H. albicans*, *H. niger*, *Primula denticulata*, *Andromeda floribunda*, and *Erica herbacea alba*. This last is really a charming variety, having pale green leaves and pure white flowers, and it blooms much earlier than the ordinary *Erica herbacea* or *carnea*. Besides the above, we had also in bloom

on the 31st of December, and noticed in the November and previous lists, *Helleborus niger maximus*, *Primula vulgaris rubra*, *Gentiana aculis*, *Veronica rupestris*, *Hepatica triloba*, *Lithospermum fruticosum*, and *Sternbergia lutea*. Notwithstanding the unfavourable weather experienced during the month, this plant has wonderfully improved both as to the quantity and quality of its blooms. All of the above are growing in the stone compartments of the rock-garden, as described in my notice of garden vegetation for November, 1875. The following table gives the number of species and varieties (exclusive of duplicates) counted in bloom on the rock-garden on the last day of each month during 1875. The number given is large in comparison with the table which gives the number of species as they came into bloom during each month. This, however, is to be accounted for by the number of duplicates grown, particularly of good flowering species, many of them being placed in positions more or less exposed to the sun, and at different elevations, where a longer duration of their flowering period is obtained. By this means, the same species of plants frequently counts in two or more months. The excess of August over July is chiefly accounted for by the number of varieties of *Calluna* and *Erica* then in bloom. In this table, also, *May* stands in excess of all the other months, as regards plants in bloom:

Number of species and varieties in bloom on the last day of each month in 1875.

Jan. 30 . . . 13	May 31 . . . 300	Sept. 30 . . . 95
Feb. 28 . . . 30	June 30 . . . 273	Oct. 31 . . . 86
Mar. 31 . . . 56	July 31 . . . 207	Nov. 30 . . . 20
April 30 . . . 150	Aug. 31 . . . 203	Dec. 31 . . . 13

SOME NEW ANNUALS AND PERENNIALS.

Eryngium Leavenworthii.—The genus *Eryngium* furnishes a small number of highly interesting perennials to our gardens, some of which are remarkable for the attractive blue or purple colour of their flower-heads and involucre leaves; others, for their Bromelia or Pandanus-like spiny foliage, and tall paniculate stems. The species of annual duration are, however, very few in number, and include probably but one possessing any interest for the horticulturist, *E. Leavenworthii*. It grows from 2 to 2½ feet high, with an erect grooved stem, branched in its upper half, and bearing palmately-divided leaves, 2 to 3 inches long, with five to seven segments, spinously out and toothed. The flower-heads are of an oblong-conical form, and about 1½ to 2 inches in length, with an involucre of narrow strap-shaped leaflets, spinously serrate and cut; the head is also crowned with a tuft of short rigid spiny leaflets, resembling those of the involucre. In their early stages the flower-heads are green, but after attaining their full growth they assume a rich deep violet tint, as well as the involucre, coronal tuft, and foot-stalk, which have, in addition, a fine metallic lustre. As in the case of *E. amethystinum*, and some other species, the heads preserve their colour for some time after being out. This species requires the treatment of half-hardy annuals, and being a somewhat late bloomer, should be sown early in heat, or in a greenhouse, in which case it will produce its flower-heads in September and October. It is a native of Texas.

Hedysarum Mackenzii.—The species of this genus *Leguminosae*, hitherto cultivated in British gardens, are exclusively natives of the Old World; the lower of hardy perennials will doubtless therefore be ready to extend a cordial welcome to the present introduction, which claims attention both as a denizen of the New World and for its intrinsic merits, for, according to Dr. Asa Gray, this species is probably the handsomest of the genus. It grows about 2 feet high, with stems decumbent at base, pinnate leaves, with about five pairs of oblong or lanceolate leaflets, and long racemes of from seven to thirty rather large Pea-like flowers, of a rosy-purple colour. It is perfectly hardy in any situation, and flowers in June and July.

Helianthus cucumerifolius.—Of the several species of *Helianthus* of annual duration which are known to science, none better deserve cultivation than the subject of the present notice. It cannot be indeed with the common Sunflower and its varieties, in the size of its flower-heads, but this is more than compensated for by the abundance with which they are produced, and the lengthened period of bloom, as well as by its less formal growth. The *Helianthus cucumerifolius* grows from 3 to 5 feet high, and is of branching habit, with scabrous, purple-stained stems, and medium-sized bright glossy green serrated leaves, of a triangularly heart shape, on rather slender foot-stalks. The flower-heads are from ¾ to 4 inches in diameter, with about fifteen deep yellow broadly oval ray florets, and a dark

purple disc, reminding the observer of the well-known *Rudbeckia speciosa*, but are twice as large. The effective contrast afforded by the colours of ray and disc is, moreover, much enhanced by the evenness of the ray, a feature in which some other species are greatly deficient. It is altogether a very desirable annual, and is certain of a favourable reception by all true plant lovers. This species is a native of Texas, and succeeds in any garden soil, with the treatment of half-hardy annuals; and will probably succeed if sown in the open ground in April. The seeds are among the smallest of the genus, being scarcely one-half the size of those of *Il. arthropylus*.

***Oenothera sinuata*.**—The typical *O. sinuata* has been long known to botanists and cultivators as producing probably the smallest flowers of any species of the genus, certainly the smallest in proportion to the size of the plant. This variety has the good fortune to be remarkable for the magnitude of its flowers, thus affording another illustration of the proverb that extremes meet—in fact, the difference between the inflorescence of the present plant and that of the original *O. sinuata* is so great, that the casual observer would suppose them to belong to an entirely distinct species. The *O. sinuata maxima* is an annual plant, reaching ultimately the height of 2½ to 3 feet, but flowering freely when only a foot high. It is of erect branching habit of growth, with small neat foliage, from 1½ to 2 inches long, ovate or ovate-oblong, and sinuately-pinnatifid. The flowers are of a bright yellow, and second in size only to those of *O. missouriensis*, being at least 3 inches across, and not seldom more, with inversely heart-shaped petals, a calyx tube about 1½ inches in length, and a cylindrical seed-vessel, which, when mature, is about 2 inches in length, and slightly curved. The seeds are small, and of an ovoid form. Being entirely free from the coarseness of some species, and a most abundant bloomer, it deserves the preference wherever *Oenotheras* are grown. It is a native of Texas, where it was discovered by Mr. E. Hall, a few years since.

***Nuttallia cerasiformis*.**—Although the time has long gone by when this plant could be called a novelty, it is still very rare in gardens, and its seeds are hardly known in this country. As is pretty well known, the genus *Nuttallia* belongs to the Natural Order Rosaceae, the present plant, the only species, being a deciduous shrub, growing 5 or 6 feet or more high, with obovate-oblong leaves, 3 or 4 inches in length, and bearing drooping racemes, of from six to ten whitish flowers, which are followed by a succulent Damson-like fruit, covered with a bloom, and enclosing a nucleus or stone, as in the Plum and Cherry. Some of the plants yield stamens only, in others these organs are absent, but occasionally specimens are found with perfect flowers. It is of neat habit of growth, and though not exactly a showy plant, is well deserving a place in the shrubbery. It is, of course, perfectly hardy. Seeds may be sown in pots or in the open ground, and are pretty certain to vegetate after a longer or shorter interval.

***Papaver arenarium*.**—In this and the following species of Poppy, the fiery red colour which characterises several favourite species of this genus seems to have attained its culminating point, for it is difficult to conceive a deeper and more striking colour than obtains in both. It is further not a little remarkable that, although their foliage is sufficiently distinct, and the capsules still more so, the flowers of these two species are so nearly alike that it is hard to point out any well-defined distinguishing feature. The *P. arenarium* is an annual plant, growing 1½ to 2 feet high, with oblong lanceolate foliage, bipinnatifidly cut, the segments terminating in a bristle. The flowers are produced singly on naked strigose peduncles, nearly a foot long, each blossom being about 4 inches in diameter, with deep crimson petals, marked with a large oblong black spot, extending from the middle to the base of each petal. Both anthers and filaments, as well as pollen, are of a blackish-purple. The seeds should be sown early, where the plants are intended to bloom, by preference in sandy soil, and the flowers will be produced in June and July. Stronger specimens will probably be obtainable by sowing in autumn.

***Papaver umbrosum*.**—This species closely resembles the preceding, but has the segments of the foliage rather broader, the flowers are somewhat larger, of a slightly deeper shade of sanguineous crimson, and the conspicuous black spot on each petal is more central. The pollen is greenish, and the capsule shorter and broader than in *P. arenarium*; further, the seeds are nearly twice as large. On the whole, the *P. umbrosum* is perhaps slightly superior to *P. arenarium*, in ornamental value, but to the casual observer the difference is scarcely appreciable. Both species are so remarkably showy when in flower as to catch the eye at a considerable distance, and arrest the attention of the most indifferent. They are natives of the Caucasus, and are therefore perfectly hardy in this country.

***Pentstemon Clevelandii*.**—This is described by the collector as a very handsome and showy new species, discovered by the gentleman whose name it bears in southern California, and is said to

grow 3 feet high, producing large dark red flowers of a very distinct character.

***Pentstemon puniceus*.**—With the colour of the much well-known *P. Torreyi*, this interesting novelty combines a much dwarfer habit, and is therefore well suited to small gardens, or beds and borders of limited size. The stems are from 1½ to 2 feet in height, with entire foliage varying from oblong at the base to narrowly lanceolate above, the flowers being bright scarlet, tubular in form, with an ample limb divided into five rounded nearly equal lobes. It is said to be a native of Arizona, and probably also of Utah and Colorado.

***Rubus deliciosus*.**—The traveller in the Rocky Mountains who should reckon on the *Rubus deliciosus* for his dessert, would have but a Barmacide feast, for, as an edible fruit, it has but small claim to the tantalising specific name given to it by Dr. Torrey, its seed being large, and covered by only a very thin coating of mawkish pulp, vastly inferior to a well-ripened Blackberry. But although this plant so bolies its name from the gastronomic point of view, in a horticultural sense it proves to be a very showy, free-flowering shrub when established, producing in June an abundance of large pure white flowers. It forms a branching shrub of erect habit, 4 to 5 feet, or more, in height, with the young growth pubescent, the leaves roundish, and more or less three to five-lobed, the lobes finely toothed, the flowers being produced in a loose cluster of from three to six. It is of rather rapid growth, and succeeds in any good garden soil. Like the seeds of many other shrubs and trees, those of this plant will often remain dormant some months.

***Salvia carduacea*.**—A very distinct species from southern California, flowering the first year from seed, and probably of biennial duration. It grows from 1 to 2 feet high, with stems sparingly branched, and clothed with white wool, the leaves being also more or less woolly, pinnatifid, the lobes sinuately toothed and armed with spines. The flowers are produced in dense, but distant whorls, the calyx being inflated and woolly, and the corolla of a delicate pale purple or lilac colour, with the middle lobe of the lower lip very large and elegantly fringed. The floral leaves and bracts are very spiny. It is probably only half-hardy, but succeeds well in the open border during the summer months. The flowers of this remarkable species may possibly vary to blue, being described as such in some botanical works, but in a specimen raised during the past summer, the flowers were lilac, as already stated.

***Aplopappus spinulosus*.**—This is a neat dwarf composite, of compact bushy habit, growing from 9 to 18 inches high, with several stems from the same root, which are much branched upwards, and amply furnished with small, rigid, pinnate, or bipinnately divided leaves from 1 to 2 inches long; the linear-subulate segments ending in a short bristle-like point. The flower-heads terminate the numerous branchlets, and are about 1 inch across, with about twenty to thirty ray florets, which, as well as the disc, are of a bright yellow. The whole plant is more or less hoary, with a soft woolly pubescence. It blooms from August until the advent of winter, flowering the first season from seed, and succeeds in any soil. As a neat and perfectly hardy border plant, of good habit and of easiest management, it can hardly fail to secure a place in all general collections of hardy perennial plants.

***Frasera Parryi*.**—The genus *Frasera*, belonging to the Gentian tribe, is scarcely known in British gardens, but includes several interesting hardy plants, all natives of North America. One of these, *F. Parryi*, now under notice, is a newly discovered Californian species. It is described by the collector as having its radical leaves margined with white, the stems bearing whorled leaves, with an elongated panicle of greenish-white wheel-shaped flowers, prettily speckled with purple dots. The flowers are about 1 inch across, and, from their number, produce a showy effect. Duration of root uncertain, but probably perennial.

***Vernonia Chamedrydes pedunculata*.**—Who does not know the charming little "weed" which enlivens our hedgerows with its deep blue flowers in early spring, the delight of childhood, and the favourite of every age? The pretty variety of it now under notice differs from the type, in its flowers being of a French white, with blue veins; the foliage is also of a darker green. It blooms abundantly in May and June, and succeeds in almost any soil and situation.

***Anemone fulgens*.**—Although this fine species is a native of the south of France, and has, therefore, been long known to botanists, it has only recently come to the front as a choice garden plant, and till now seed of it has been unobtainable. It is so brilliant a species, that it will be welcomed by all classes of horticulturists, and well deserves a place even in the smallest garden. It grows about 9 inches high, producing in April and May from strong tubers, a profusion of dazzling vermilion-scarlet flowers, rather smaller than the common *Anemone*, with a light coloured ring around the stamens. It is

most vigorous and floriferous in rich, loamy, well manured soil, but will succeed in almost any good garden soil. Sow in March and April in pans of light soil, and transplant in early autumn to the open ground.

Celosia pyramidalis.—The value of the *Celosia cristata* pyramidalis as a decorative plant is now widely recognised, and it is equally well known that, like many others, it varies much when raised from seed, and that some forms of it have been obtained, which greatly surpass the average varieties. That now sold under the name of Reid's Perfection, is one of these, and appears to be a really important acquisition. It is quite robust in habit, attaining a height of 2½ feet, and is furnished to the base with gracefully drooping lateral shoots, which are profusely clothed with plume-like spikes of the purest magenta. If properly managed, the plant will flower continuously for several months together. It is particularly adapted for the decoration of the greenhouse in autumn, and if struck from late cuttings, the flowering season may be prolonged till January.

Clarkia elegans flore pleno.—Double varieties of the *Clarkia elegans* have long been cultivated, and of late years a considerable improvement has taken place in their character. The varieties raised by Mr. Hardy appear to eclipse all previous forms of this plant, and received the award of two first-class certificates from the Royal Horticultural Society in July last. They are described by the raiser as resembling in substance the best double Balsams, which renders the flowers much more durable in character than the ordinary forms. whilst in form, boldness of habit, richness, and novelty of colour, they surpass all other named *Salmon Queen*, with flowers of a salmon-red tint, the other named *Purple King*, of a deep rosy-purple.

Theris umbellata hybrida nana.—This seems to be a very promising variety of Candytuft, and is described by the introducers as exceedingly floriferous, and very remarkable for the numerous and brilliant colours which it yields, the varieties including pure white, rose, lilac, carmine, red and dark purple, with intermediate shades. The plants are of dwarfer habit than the ordinary forms, and make handsome tufts.

Kaulfussia amelloides kermesina.—Until now, the *Kaulfussia amelloides* has yielded but two varieties, differing from itself, viz., the so-called *rosea*, with a rosy-purple disk, and the ray of a paler shade; and the *atroviolacea*, with flower-heads of a deep violet. The novelty here noticed is described as having flower-heads of a fine deep carmine, and will be a welcome addition to the list of dwarf hardy border annuals.

Loasa hispida.—The curious structure of the flowers in this genus, and their showy and often well-contrasted colours, would make them popular plants, but for the drawback of the stinging hairs with which most of the species are clothed. *L. hispida* is, however, so ornamental, that its exclusion from the garden on such slight grounds is not warranted, for, when once planted out, it need not be handled. It grows from 12 to 15 inches high, branching considerably when strong, and bears deeply bipinnatifid foliage of an oblong lanceolate form. The flowers are borne in terminal racemes, of five or six drooping blossoms, which are about 1 inch across, the boat-like petals being of a clear lemon-yellow, and the centre of the flower prettily variegated with green and white. The plant blooms in August and September, for some weeks in succession, and is of easy management as a half-hardy annual, in any light fertile soil. A native of Brazil, and may probably be synonymous with *L. ambrosiifolia*.

Oxalis rosea alba.—This is a pure white variety of the well-known *Oxalis rosea*, one of the most popular of half-hardy annuals, and affords a pretty contrast to it. It appears to come perfectly true from seed, and may be recommended as a very desirable little plant, suitable, like the type from which it has originated, for edgings, as well as for pot culture.

Passiflora pectinifera.—Of the annual Passion-flowers, of which the number is somewhat restricted, but one, the *P. gracilis*, is at all common in gardens, and, though not a showy species, it may be recommended for occasional cultivation as a half-hardy climber. In the *P. pectinifera*, a far more remarkable annual species, is presented to the notice of the amateur. It is described as being the finest of its class. The foliage is three-lobed, with a cordate base, and of a velvety-green colour. The flowers are of a carmine-rose colour, upon a pure white ground, and are surrounded by an involucre of three deeply pectinated leaflets, each division of which is terminated by a gland. Being a native of Brazil, it probably requires to be grown under glass, or upon a warm wall, in which situation its growth is said to be very rapid.

Zinnia Darwinii.—Under this name, an interesting hybrid variety has been obtained by a German firm, which is said to have originated from a cross between the double *Zinnia elegans* and the double form of *Z. laegeana*. They are described as combining a

regular branched habit of growth, the utmost variety in colours, with perfect doubleness of flower up to the last stage of blooming. The plants thus obtained differ somewhat in habit and height, as well as in the form of the flower-heads, which are globular in one variety and conical in another. The colours of the mixture sold are said to include white, yellowish-white, white tinted rose, yellow, sulphur, golden-yellow, salmon-rose, lilac, deep crimson, deep violet, deep purple, deep scarlet. The variety *vittata* comprises six colours, viz., white red-striped, white rose-striped, white crimson-striped, sulphur crimson-striped, yellow scarlet-striped, and sulphur purple-striped.

Silene saponaria.—This is described as a magnificent border plant, forming fine tufts 8 inches high, covered with large bright rose-coloured flowers, with deeply out petals. For masses, as well as for pot culture, it is very effective and pretty, and is altogether a first-class novelty.

Phlox Drummondii grandiflora splendens.—The new large-flowered varieties of *Phlox Drummondii* prove to be decided acquisitions, and the variety above named especially merits recommendation, it being the finest of the *grandiflora* section yet introduced. Its flowers are very large, of great substance, of a vivid crimson colour, with a pure white centre, and the habit of the plant is free and robust. It will doubtless prove a splendid bedding plant. The varieties, *kermesina alba oculata* and *violacea oculata alba*, are but little inferior to it.

Salvia sanguinea grandiflora.—This species is represented as similar to *S. coccinea*, but produces flowers twice as long. It forms a large bush of shrubby habit, growing 3 to 4 feet high, all the shoots being terminated by long spikes of scarlet flowers furnished with white and lilac bracts. It is hardy in the south of France, and well suited for masses. Said to be a native of North America, but is doubtless a Mexican plant.

W. THOMPSON.

Ipswich.

Renovating Patchy Lawns.—Lawns sometimes become patchy, especially those subjected to much treading. Under such circumstances, where the roots of the Grass are not wholly destroyed, a slight surface dressing with rich soil early in the spring will induce a luxuriant growth throughout the summer, except in the case of light and shallow soils, where the roots are growing thinly. With these, the best plan is to cut out the small spent patches, and replace them with fresh healthy turf. This should be done not later than March, in order that new turf may be established before scorching weather sets in. Grass seeds do very well when sown in out-of-the-way places; but on parts where there is much traffic they get trodden down and often killed before they have time to form a good turf.—J. Murr.

Cypripedium Passerianum.—Can you tell me if this Lady's-slipper is in cultivation in England, as I fail to find it mentioned in any of the catalogues which I have. This magnificent plant grows freely in moist, sheltered spots in the Sierra Nevada of California, near the Yosemite Valley; and I found several specimens in full flower on the 28th of May, 1874, between Clark's Ranch and the Mariposa Grove of Sequoia (*Wellingtonia*) gigantea. Its leaves are ovate, sessile and amplexicaul, and from 2 to 3 inches long. The stem is erect, and from 8 to 12 inches in height. The flowers are from one to three in number, the sepals and petals being of a rich, chocolate colour, and the lip pure white. As I found this *Cypripedium* growing by the side of *Lilium Washingtonianum*, I feel sure that it could be easily cultivated in England; and it would be an interesting addition to any collection of Orchids.—ROSE G. KINGSLEY, *Dyflsch.* [*C. Passerianum* does not appear to be in cultivation under that name; indeed, many consider it to be only an American form of our native *C. Calceolus*. The plant is described and figured in Hooker's "Flora of North America," t. 206, and is one of Richardson's species synonymous with his *C. parviflorum*, described in "Franklin," Appendix i, 320. We have a whole group of so-called species, all very closely related, the main distinction being geographical distribution; among these are *C. Calceolus*, *C. pubescens*, *C. parviflorum*, *C. Passerianum*, and *C. cordigerum*. The last-named, according to Lindley, is but a white-flowered form of *C. Calceolus*, a widely distributed plant found in Europe, Dahuria, and, according to Thunberg, a native of Japan.—B.]

Dark-leaved Cannas.—Do dark-folaged Cannas keep their colour when planted in the open air; and what are the names of some of the best dark-leaved kinds?—W. J. M. [Dark-folaged Cannas keep their colour when planted in the open air; but they do not stand the winter so well as the green kinds. The following twelve are the very best, both as regards their rich dark tints and free-flowering properties, viz.:—*Bavillesi*, *Bihoreli*, *Bonnetii*, *maior*, *discolor*, *violacea*, *expansa*, *terrandii* (this will bloom all through the winter in a warm greenhouse), *Marchal*, *Vaillant*, *metallica*, *nigricans*, *Rendallii*, *violacea superba*, and *Warszewiczi zebrina*.—B. COLE.]

THE ONION-FLY.

(ANTHOMYIA CEPARUM.)

The Onion-fly was unusually destructive last season; and, in some parts of the country, as in Lancashire and Derbyshire, for instance, it has nearly wholly ruined the crop. There is, however, no evil without its countervailing good, and one good, though it may be very dearly bought, is that we are likely to know the details of the life of the destroying insect a little more accurately than we previously did, besides getting

Fig. 1.—Section of Onion, showing the position of the eggs and direction in which the larva enters the bulb.

any blanks in its history filled up. One of the cultivators who has suffered from its ravages (Mr. J. Knowles, of Blackburn), has paid particular attention to it, and he has favoured us with some memoranda relating to it, which may be of interest to the Onion grower, the more that they relate to the depositing of the egg, which, we need scarcely say, is the most important point in all efforts to counteract insect damage, and that to which our attention ought to be mainly directed. After the

Fig. 2.—Onion-fly. Larva, chrysalis, and perfect fly; all magnified.

egg has been deposited it is usually too late to interfere with effect. The mischief has been, if not already done, at least already promised, and promises for evil are a kind of promises that are generally only too well kept. It has usually been said that the eggs of the Onion-fly were deposited upon the leaves of the Onion, close to the surface of the ground, and that the grubs penetrated through the outer leaf, making their way down to the base of the bulbs between the leaves; but, from the observations of Mr. Knowles, it appears that this is not quite the course of proceeding. His observation is that the eggs are deposited on the joints of the leaves (as at *aa* in fig. 1) in small clusters from two to seven in number,

probably at night or in the early morning. They are oblong, white and waxy in colour, and from one-tenth to one-eighth of an inch in length. On being touched these eggs seemed to him to give a little spring off the plant towards the root of the Onion. These were probably eggs ready to hatch. We do not see otherwise why the eggs should not at once have been laid in or on the ground. By being glued to the leaves they were kept free from damp and creeping enemies, and it would only be at the termination of the period which it was for their good that they should remain there, that means were provided for allowing the eggs or larvæ to get to the next position for which they were destined. It seems most likely, therefore, that the embryo in the eggs that become thus displaced must have reached such a stage of development that it would feel a touch through the egg-shell, and make a wriggle in consequence, which might start the now somewhat worn glue that binds it to the leaf and allow it to fall. On this head we ask for fresh information from Mr. Knowles in another season. After they have fallen, whether in the shape of eggs or larvæ, he found that they invariably made their way to the root, but by a quite different route from that usually supposed. Instead of entering at the top of the root they make their way to its bottom (as shown in the cut at *b*), and eat their way into the bulb from the outside, at or near the base. We have no doubt that this is a correct explanation of the place and mode in which entrance is effected. It is exactly at this place, and in this way, that the Merodon clavipes, which we lately noticed (see p. 363, Vol. VIII.), makes its entrance into the bulb of the Narcissus. Their gnawing there soon stops the growth of the bulb, and causes an offensive smell, the bulb decaying and putrifying, partly owing to the slimy matter secreted by the grubs, and partly from natural decay. June and July are the months in which they are most numerous, but they have been found as early as May, and sometimes a very late brood may be met with even in winter, there being a constant succession of maggots, owing to the number of generations produced in the summer. The larvæ are broad at one end and pointed at the other, as shown in fig. 2. They are undistinguishable from those of the Turnip and Cabbage flies, and from many other species of *Anthomyia*. They are said to attain their full size in fourteen days, when they leave the Onion and descend into the ground to undergo their metamorphoses. They there assume the chrysalis or pupa stage; their hardened skin turning into elliptical chestnut-coloured cases, in which they pass from ten to twenty days in summer before the fly is perfect, and then it comes out; the autumnal pupæ continue in that state through the winter. The fly produced by them appears in April or May. The perfect male insect is of an ash colour, roughish, with black bristles and hairs, and the eyes are contiguous and reddish, the face silvery white, antenna black; there are three obscure lines down the thorax, and a line of long blackish spots down the centre, more or less visible in different lights; the wings are transparent, slightly iridescent tinged with ochre at the base, the nervures, pale brown; poisers, ochreous; legs, ashy brown. The female is ochreous or ashy grey, clothed with black bristles and hairs; the eyes are reddish and remote, with a light Chestnut stripe between them, bifid and darkest at the base; face, yellowish-white. (See fig. 2.) Many remedies have been suggested and tried with various success. Curtis mentions the following, viz.:—Dressing the beds with nitrate of soda, covering them with a layer of half-an-inch of charcoal, mixing it with the earth before the seed is sown; spreading or sprinkling with coal-dust, lime, soot, salt, or watering them with a strong decoction of worm-wood, soap-suds, &c. These do not seem to have done much good. Mr. Knowles has tried most of them without effect. Rolling where the soil is light has been recommended; such a soil seems to be more favourable to the development of the fly than that of a stiff clayey nature, through which it is more difficult for the mature insect to make its escape on emerging from the pupa; and that many must perish in soil of this description is obvious from the fact that numbers of pupa have been found imbedded in the clay several inches underground, from which it would have undoubtedly been impossible for the fly to get out under ordinary circumstances. Curtis speaks of pulling up the affected

bulbs, whose state is first shown by the yellow drooping leaves, and destroying them at once, to prevent further damage, as one of the most effectual cures, as it is hopeless to think of saving the Onion when the grub has established itself in it; but the above explanation of the laying of the eggs and the mode in which the larvæ get into the bulb show how fruitless any such plan must be. It might, indeed, be of use if the larvæ came out of one bulb and wandered into another, but there is no reason to think that they do so; on the contrary, everything seems to indicate that the grubs pass their larval life in the bulb into which they first enter, and only leave it when about to enter into the pupa stage. The course that we would recommend is, for the cultivator, at the time when the fly appears in April or May, to keep a very sharp look out and to destroy the first brood, which is his only chance. - Let him crush the embryo, so to speak, in the egg. Let him pass his hands gently over the leaves at the points we have indicated in the annexed figure, and if he finds any eggs let him remove them then or crush them gently by hand. If he watches at the right time it is only a week or ten days' daily examination. It is, perhaps, impossible so to watch on very large crops, although even then, where it has once been found that the eggs are being laid, we think it would be money well laid out to employ many female hands to go gently over the leaves and draw off or squeeze the eggs.

ANDREW MURRAY.

TREES AND SHRUBS.

VARIETIES OF BOX.

The different varieties of Box are all evergreen shrubs or small trees, and highly valued, not only for their ornamental appearance, but for their timber. The following are the most distinct and worthy of attention:

The Common Box (*Buxus sempervirens*).—This species is not only indigenous to England, but to a wide range in southern Europe and Asia Minor. It forms a densely branched shrub or tree rarely exceeding in this country 20 feet in height, but found frequently on the Continent rising to above 30 feet. The wood is much superior in quality to that of any of the other species, and is of great importance, from the fact that it is the best that has yet been discovered, for wood engravers' blocks, for which it is in great demand. The home supply of this valuable timber is now very meagre, and to meet the large and ever-increasing demand, great quantities are imported from the more accessible of its foreign habitats; even these, however, are reported as being nearly exhausted, and there is reason to believe that it will soon become a scarce and very expensive commodity. The general appearance of this shrub, with its symmetrical habit of growth and bright shiny green ovate leaves, is so familiar to even the most careless observer of the productions of the vegetable kingdom as to render description superfluous. The flowers like those of all the other species, are very small, of a light or yellowish-green colour, generally profuse, and in perfection in April or May. It is here very little planted for its timber alone; but no evergreen is more frequently met with in our shrubberies and pleasure grounds, where, if in anything like favourable circumstances in regard to soil and situation, and with plenty of space on every side to develop its branches, it forms a remarkably handsome, though somewhat slow-growing specimen. From its naturally close, bushy habit and short twiggy branches, the common Box is one of the most useful evergreens for garden hedges. It may be pruned or clipped into any shape with the greatest impunity; and in the days when topiary gardening was in fashion, it shared with the Yew the place of honour in the formation of architectural designs and figures of men and animals, the outlines appearing as sharp as if they had been carved out of a solid substance. In common with all the other species, this plant succeeds well in shady aspects, and makes excellent shelter for game when massed as underwood among old trees. While there are few soils in which this shrub will not grow and even thrive, it prefers such as are of a light porous character, with a warm, gravelly, or sandy sub-soil; and when planted in stiff clay, ample provision should always be made for the drainage of superfluous moisture. Of what is regarded as the typical species, there are a remarkably large number of varieties in cultivation, differing more or less in stature, habits of growth, and foliage. They are all very interesting, and in not a few cases quite equal, if not superior, to the parent as decorative shrubs. Of these the undermentioned are worthy of special attention:

B. s. arborescens.—This is a very handsome form, with a more robust habit of growth, longer branches, and larger, lighter green leaves than the species with which it is found associated both in its English and foreign habitats. It is one of the most desirable and popular of the varieties.

B. s. arborescens aurea marginata differs only from the preceding in having its leaves narrowly margined with bright gold.

B. s. arborescens Handsworthensis.—This grand form originated at, or at least was sent out from, the Handsworth Nurseries, near Sheffield, a few years ago. It has a broad, bushy habit of growth, with broad, deep green leaves, and is one of the finest and most distinct of the varieties.

B. s. arborescens Handsworthensis aurea marginata has its leaves prominently margined with gold. It is a most effective plant.

B. s. angustifolia, with much narrower leaves and a dwarfier habit of growth than the species, is a pretty compact little shrub, valuable as a margin to the stronger-growing, or for small borders or beds of diminutive evergreens.

B. s. angustifolia aurea differs from the preceding in its leaves being tipped or margined with gold.

B. s. argentea variegata.—This variety has its leaves freely variegated with silver, and, having a neat bushy habit of growth, is a great favourite with planters of choice shrubs.

B. s. aurea marginata.—The leaves of this sort are beautifully tipped and margined with gold, giving it a fine effect, and rendering it very valuable for grouping with the other forms for winter effect.

B. s. japonica.—By some writers regarded as a species, but so closely resembling the common Box as to justify the opinion of others that it is merely a form of that species. It is quite hardy here, and forms a very distinct and handsome shrub. The habit of growth is similar to that of the species, but the leaves are nearly double the size, and of a darker green colour. It was sent home a few years ago from the Continent, and was said to be originally from Japanese gardens.

B. s. japonica aurea variegata.—This grand acquisition has its leaves beautifully blotched with bright gold, and is one of the best of our hardy variegated evergreens, producing a most striking contrast in the mixed shrubby border, and peculiarly valuable for winter-bedding in the flower garden, for which purpose it is well worth the attention of gardeners, who are often at a loss to find plants of neat growth, effective foliage, and at the same time sufficiently hardy to retain their beauty and freshness during the winter and spring months.

B. s. latifolia has larger and broader leaves than the species, which it otherwise very much resembles.

B. s. latifolia stricta has foliage similar to the preceding, but differs in its style of growth, which is more compact and columnar.

B. s. pendula.—This variety has a decidedly weeping habit of growth, and when left to itself has a rambling, not very elegant, appearance. Trained, however, to a single stem, or grafted as a standard upon the upright varieties, it forms an exceedingly fine specimen, well suited for a lawn, or prominent position in the flower garden or shrubbery. It deserves to be much more frequently planted.

B. s. rosmarinifolia.—A curious dwarf-growing variety, with narrow leaves of a deep-green colour, giving the plant an appearance suggestive of a miniature Rosemary.

B. s. suffruticosa or *nana.*—This is the common dwarf Box, a plant unexcelled for edgings to garden walks, and too well known to need description.

B. s. myrtifolia.—A distinct and pretty dwarf-growing plant, with narrow oblong leaves.

B. s. thymifolia.—An exceedingly neat-growing dwarf variety, with short tiny branches, and very small narrow leaves. It is an admirable rockery plant, and useful for the winter adornment of flower-garden beds.

B. s. thymifolia aurea variegata.—This differs only from the last in its leaves being prettily variegated with light yellow.

The Minorca Box (*B. balearica*).—Indigenous to the Balearic and other islands in the Mediterranean, as well as to Italy and Turkey, where it forms a magnificent tree of from 60 to 80 feet in height. It was first introduced into Britain in 1780. The leaves are similar in form, but nearly four times as large as those of the common Box, and when grown exposed to the sun, of a much lighter green. They are thick and leathery in texture, and very abundantly set on the branches. The flowers are small and inconspicuous, of a light yellow colour, and generally expand in July. In our gardens it is only seen as a moderate-sized shrub; and, though very properly classed among hardy evergreens, it only succeeds well in the milder districts or in well-sheltered situations. Its habit of making late autumn growths renders it peculiarly susceptible of injury from frost, by which the points, and sometimes the

whole of the young shoots, are destroyed. It is, notwithstanding, such a distinct and handsome species, that it should have a fair trial wherever a favourable situation is at command. As it thrives well in the shade, it is found useful for clothing walls or other buildings with aspects in which, from want of sun, few other evergreens or flowering shrubs would succeed. It requires a dry porous soil and a warm sub-soil.

The Chinese Box (*B. sinensis*).—This species was first sent home from China in 1802. It is of a dwarf habit of growth, rarely exceeding in its native habitats 3 feet in height. The leaves are smaller in size than those of the common Box, broadly ovate in form, and of a light green colour. It is here rather tender, but succeeds tolerably well in sheltered situations, forming a neat, round, very compact bush, useful for small garden beds, where plants of slow growth and regular outline are frequently desirable.

***B. s. longifolia*.**—This form is of recent introduction from China. It has a similar habit of growth to the species, but has much longer leaves. Though like its parent, scarcely equal to our winters, except in well-sheltered situations, it is a pretty little plant, and well worthy of a snug corner among choicest shrubs.—“The Gardener.”

Best Time for Moving Rhododendrons.—Can one safely transplant Rhododendrons at this time of the year into not particularly good soil? Which are the hardest and best kinds for so doing, and how late on towards spring can one transplant them with any prospect of success? If Rhododendrons cannot bear moving now, what evergreen shrubs would stand transplanting at this season? The spaces required to be filled up are in rather exposed situations, the soil being, as already mentioned, poor. The locality is not far from coal fields in Pembroke-shire.—WHITE PRIMROSE. [There cannot be a better time than the present for transplanting Rhododendrons—i.e., as soon as the frosty weather has disappeared; they may also be moved with perfect safety up to next May. The most hardy kinds are hybrids from Catawbiensis.—JOHN WATERER, Bagshot.]

Variagated Conifers.—With this I send you specimens of *Pinus sylvestris aurea*, *Pinus austriaca variegata*, and *Pinus Pinaster variegata*. The first is a true golden variety of Scotch Fir, one which grows as freely as the normal form, and one which in winter assumes a handsome golden colour. The variegation in the case of *P. austriaca* is also very striking and is one which contrasts well with the dark foliage of other Pines. The *Pinaster variegata* is, perhaps, the finest variegated Conifer known, but unfortunately it is most difficult to propagate. Besides these we have the golden American *Abies-vitæ* and the yellow Lawson Cypress, so that we have sufficient finely-coloured Conifers to produce as fine an effect in winter, as the Golden Poplar and Golden Laburnum produce in summer. Fine winter effects may also be obtained by planting *Acer rubrum*, *Cornus coccinea*, golden Willows, and that most beautiful plant *Cryptomeria elegans*.—W. W. JOHNSTONE, Lawson Company's Nursery, Bangholm, Edinburgh.

Desfontainia spinosa in Ireland.—This, says a correspondent of the “Gardeners' Record,” is the most distinct and beautiful hardy evergreen shrub in cultivation. Perhaps I ought to qualify the word hardy, as, from personal experience, I can only assert its hardness as far as the province of Munster is concerned. At Messrs. Sanders' nursery, Cork, numerous plants of it may be seen growing in the open quarters, and at Belgrave, near Queens-town, it appears to be quite at home; and the same may be said of it at Creg, near Fermoy, where, under the care of Mr. C. Percival, it blooms as freely as a hardy Azalea.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Deodar as a Vase Plant.—Deodars look well in vases connected with outside stairs and balconies. In such positions their pale green pendent branches have a graceful effect. The Deodar withstands all kinds of exposure, even about towns. If planted when in a small state, in good loam, it will last a long time even with its roots confined in a vase.—J. MUIR.

A New Laurel.—Everybody knows the common Laurel (*Cerasus Lauro-cerasus*), but comparatively few are acquainted with the new *Camellia* or white-leaved variety, which is so distinct from all the forms of the common and *Colchic* Laurels that it well deserves attention. Its growth in Messrs. Lee's nursery, at Feltham, is robust and erect, the leaves, which are glossy and rugose, being each curved, as in the new *Croton volutum*.

The Hungarian Oak (*Quercus conferta*).—A tree of this handsome deciduous Oak may be seen in the Royal Botanical Gardens, Edinburgh, where it is called *Q. pannonica*. It was procured from Messrs. Lawson's Nursery twenty years ago, and was removed to its present situation in 1866, where it was planted by Sir William Grieve Craig. It is 20 feet high, 36 feet in spread of the branches, and 23 inches in circumference of stem. Its foliage is very beautiful, nearly 7 inches in length, and 3 or 4 inches in breadth, and almost sessile. This species is a native of Turkey in Europe, where it forms large forests. The Acorns are sweet to the taste, and are eaten by the Servians.

THE INDOOR GARDEN.

FORCING IRISES, CROCI, AND OTHER BULBS.

MR. ALLAN'S hints (see p. 27), on the forcing of *Iris reticulata*, should be noted by all who want a really charming flower in winter. I object strongly to forcing hardy plants, but there are just a few which flower at such early and usually inclement seasons that the beauty of their flowers is either partly or entirely destroyed if they are left without any shelter. Among them I should place *Iris*, or, more properly *Xiphion reticulata*, *X. Hisirio*, and several of the autumn and winter Croci. Many of these latter have been struggling with the cold and dull weather for a month past, and though the flowers are fully developed they have been unable to open though they are protected by a frame. If kept plunged until the buds appear, and then moved into a greenhouse, they open freely, and can be returned to their usual quarters when the flowers are over. All small bulbs, however, if kept in pots unplunged, whether indoors or out, suffer very much from the changes in temperature and moisture to which their roots are subject. I have found that the best way to enjoy the beauty of *Calochortis* is to grow them in pots plunged in a frame and brought into the house to flower. They are thus protected from slugs and wet, and can be dried off more gradually and thoroughly than if planted out altogether. I believe that *Calochortis*, like most other bulbs coming from a country where the summers are hot and dry, cannot be grown successfully in this climate, unless artificially rested in autumn, though when divested of the thick fibrous coats which cover the bulbs in their own country, they must not be allowed to lose any of their similar plants as long as possible is, that they are kept from growing at a season when they are liable to injury from spring frosts. I hope that those who have friends in the Rocky Mountains will try and procure several species of this lovely genus, which are still unknown in Europe. Besides the eleven or twelve species now in cultivation, eight of which I flowered last season, there are at least ten more, of which *C. Lyalli*, *C. nitidus* and *C. apiculatus* are found in British Columbia; *C. Nuttalli* and *C. flexuosus* in Utah and other states; *C. Hartwegi* and *C. purpurens* in northern Mexico. H. J. ELWES.

Bougainvillea spectabilis.—How can I induce this *Bougainvillea* to produce its mauve-coloured bracts? We have a plant here eighteen months old, which is about 7 feet high, and well furnished with side shoots, but they are not very strong. It is in a 14-inch pot, and trained to the back wall of a rather cool stove. It has had little or no water for the last six weeks, but still it is quite green and growing a little. I may add that the pot in which it is growing is plunged to the rim in a border of soil. When may I expect it to produce its finely-coloured bracts?—THOS. SPELMAN.

Painting Glasshouses.—I have for many years used anti-corrosion paint for all outside work, and, on the whole, I prefer it to white lead. I think it wears better in exposed places, and consequently keeps the wood in a better state of preservation. Formerly I applied two coats every two, or in some rare instances, three years; now I give one coat every year, and I believe this plan is at least as cheap as to give two coats at longer intervals, as I find that I have now very little loss to put to re-place, which used formerly to add a good deal to the expense of painting. I know some painters have a prejudice about the anti-corrosion paint, and, from its being composed largely of ground glass, it has a tendency to wear out the brushes used in applying it; but, brushes are comparatively cheap; at least they form but a small item in comparison with labour and paint.—H.

Tuberose Culture.—We have had several allusions in THE GARDEN to the good Tuberoses in cultivation in America. The following throws some light on their culture:—“It is well known that to bring Tuberose bulbs to perfection a long and rather hot season is required. In the more northern states of America the summer is scarcely long enough to mature the small offsets planted for the purpose of producing blooming bulbs; and, even in localities where they do come near enough to enable the propagator to keep them over without delay, it requires two or three seasons to produce a large blooming bulb from the small offsets with which we usually commence as a starting point. Then again, the bulbs grown in a cool climate are seldom as firm and solid or bloom as freely as those from a warm one; hence the oft-repeated announcement in florists' catalogues of 'genuine imported Italian Tuberoses.' Tuberoses of excellent quality are, however, produced in New Jersey and throughout the middle states; but even in those states it generally requires two years to produce blooming bulbs.”

PLATE IV.

THE GREAT ARAUCARIA AT DROPMORE.

THE plate issued with the present number of THE GARDEN does not represent a new flower or valuable fruit, but what is perhaps the finest specimen in England of the most distinct of all our introduced hardy trees—the great Araucaria at Dropmore, near Maidenhead. In testing the fitness of the process we employ for the representation of landscape and tree sketches as distinguished from portraits of flowers and fruits, we selected Mr. Vernon Heath's portrait of this grand tree, which, even in the grounds at Dropmore, where there is such abundant wealth of Coniferous trees, is one of the most interesting. It is about 60 feet in height, and well furnished with branches from bottom to top. It is about forty-five years of age, and when first planted was only 2½ feet in height. In southern Chili this Pine grows to the height of 150 feet; but, although introduced as far back as 1795, we believe the highest tree in this country is that which we now figure. Mr. Barron, writes thus respecting this tree:—"I cannot do better than state what has been done with this Araucaria at Elvaston. In November, 1836, I planted one, 3 feet 9 inches high, in the grounds at that place. This plant I lifted myself in the late Mr. Donald's nursery, at Woking. It was at that time the specimen tree in his nursery arboretum. I had to pay 6 guineas for it, besides replacing it with another worth 50s. I was at that time fully aware of the evils of pot-bound trees; but I knew that it had stood too long to run the risk of uncoiling its roots; therefore I planted it with a good ball of earth undisturbed, and for fifteen years consecutively it made an average growth of 20½ inches; and during three years of the most rapid growths it averaged 2 feet 2½ inches, and made three whorls of branches in two years. This tree was planted in a good depth (3 feet) of silicious loam well drained, and had each year a liberal supply of water during the growing season. In the winter of 1838 the thermometer fell 8° below zero, yet none of our Araucarias were injured. This fine tree was the admiration of all who saw it, until it was over 33 feet in height, then it stopped growing; and I purposed removing it to some place in the plantations, on one of my transplanting machines. I then discovered the true cause why it ceased to grow, viz., there were only two roots alive, all the others were strangled, and many of the earlier strangled ones were rotten; the whole of this mischief arose from the plant having been pot-bound when young. This tree, which grew in a most conspicuous place, in front of Elvaston Castle, was immediately replaced with another fine plant, which is now a noble specimen. Naturally, the Araucaria is generally found growing luxuriantly on soils with a rocky substratum, where its roots are kept moist by rain and falls of snow. It grows on the western declivities of the Andes, and even reaches the snow-line. It will grow in any soil where the forest trees will flourish. It is easy of removal at any age or size, as its roots are flexible, and furnished with abundance of fibres. With many amateurs there exist strong prejudices unfavourable to the introduction of this noble tree; two I may mention, which are founded on a want of experience of the true habit and constitution of the Araucaria. 1. I have repeatedly heard the remark, 'I do not like that plant.' 'Why?' 'It looks so stiff and formal.' No doubt the remark is just when applied to a young specimen; but the adult tree, when well grown, combines both dignity and gracefulness in a high degree. 2. Since the morning of Christmas, 1860, when so many fine plants were destroyed by frost, many have an idea that this tree is not hardy enough for this country; but that is a mistake. The most trying frosts which we have had during the last fifty years occurred in the winter of 1829-30, March 20th, 1837, January 28th, 1838, and January 20th, 1854; in this case the thermometer was 8° below zero, with a perfect hurricane from the N.E., so that all our Deodars were leafless as Larches in the spring, and the temperature on vegetation might be said to equal 15° below zero; yet our Araucarias were untouched. The true cause of the destruction of Araucarias on December 25th, 1860, was the high-growing temperature up to within a week of Christmas, when large Oaks, Hollies, and Ash trees succumbed, which had not been injured for 200 years before. The thermometer stood at 80°,

Fahrenheit, out-of-doors in October, 1860." A fine specimen of this Araucaria growing at Woodstock, Kilkenny, of which we gave a woodcut illustration in THE GARDEN (see p. 399, Vol. III.), has reached a height of upwards of 50 feet; and, in England, trees of it, varying between that and 60 feet, are not uncommon.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Propagating Bedding Plants.—Some of these should now be prepared for propagation, as many of them do better when struck in spring than when used in the form of autumn-struck plants. *Verbenas*, for instance, propagated in autumn generally get hard and stunted during winter, and do not grow away when planted out nearly so freely as the softer spring-rooted plants. To ensure their rooting freely, store-plants that were prepared early in autumn should be placed at once in a little warmth; a night temperature of 50° will be sufficient; but a few degrees more will do no harm, provided the plants are placed on a shelf, or in any other position where they will be near the light. Whilst there, keep them well supplied with water. Liquid manure once a week will be of great benefit to them, and will enable them to produce more cuttings than if no stimulant is used. *Verbenas*, particularly the white varieties, are very subject to mildew; and, as soon as this is detected, dust at once such as are affected with sulphur. *Lobelias* of the speciosa type and *Heliotropes* should also be placed in warmth; for, unless the shoots to be taken off are young and soft, they will not root freely. *Ageratums* require to be treated in the same way; the compact-growing dwarf varieties, such as Tom Thumb or Imperial Dwarf are the best kinds, as their close habit renders them more desirable than the taller sorts. Where *Ageratums* have to be raised from seed, it should be sown at once in well-drained shallow pans in sifted loam and leaf mould, in equal parts; to which add a little sand, filling the pans up to within an inch of the rims. Press the surface quite smooth, and sow the seed moderately thick, covering slightly with a little finely-sifted soil. Place the pans in a temperature of 50° or 55°, and as soon as the plants make their appearance. Keep them near the light to prevent "drawing;" where, however, there is at command a sufficient number of *Ageratums* and *Lobelias* from which to take cuttings it is better than raising them from seed, as, in that way, they cannot be depended upon to come true, *Ageratums*, in that case, often coming too tall, and the *Lobelias* deficient in colour. The yellow *Pyrethrum* is much better raised from seeds than from cuttings or division of the roots. If seeds are sown now and put in a little warmth they will be up in a short time, when they can be either placed in small pots or in boxes. *Pelargonium* cuttings, struck several together in 5 or 6-inch pots, should be kept where they will make a little growth and not be too much crowded, or they will become "drawn;" it is better not to pot them off singly yet, unless they can be placed for some time in a temperature of 45°, in order to induce the production of roots. Roots of *Dahlias* and *Salvia patens* should be looked over in order to see how they are keeping; they should be placed where no frost can reach them, but not where the tubers will shrivel much. If the old stems of *Dahlias* have not dried well, but, on the contrary, are wet and mouldy, the roots should be removed for a short time to a place where they will be less subject to damp, or the eyes at the collar will most likely perish; they must not, however, be put where there is warmth sufficient to start them into growth. Cuttings of *Chrysanthemums* should now be put in; for, if they are not struck until spring, they do not flower so well unless they are very attentively treated through the summer. In selecting the kinds to grow it is well to consider whether they will be required early or late. By means of a judicious selection of sorts a succession may be had, if desired, from October to the end of the year, the latest-flowering varieties being generally the most useful. The cuttings should be put three or four together, in a small pot, in ordinary loam, to which has been added one-third leaf mould and a sixth part of sand; they will root in a greenhouse temperature covered with bell or hand-glasses kept sufficiently close to prevent flagging, but not so as to cause the leaves to damp off; the soil should be kept quite moist, and the pots ought to stand on soil, sand, or some other moisture-holding medium, and not on dry shelves. If they can be placed in a temperature of 50° they will root all the quicker.

Hedge-cutting.—The growth of a hedge is much influenced by the shape to which it is cut; nevertheless, this is a point which seems to receive less consideration than it deserves, even from those who ought to be acquainted with the effects of yearly confining growth within certain limits. Observe, for instance, the size to which uncut plants will grow, compared with such as are regularly trimmed in, and the same holds good with respect to any particular

THE GREAT ARAUCARIA AT DROOPMORE (60 FT HIGH)

branch or branches upon a given plant that are left to grow to a larger size than the rest. In all cases it will be found that the branches, from whatever part of the plant they may be produced—base or top—will be proportionate in strength with the extent to which they have been allowed to grow; hence it follows that, in cutting a hedge, the wider it is left at the bottom, by permitting the lower branches to extend, and by keeping the top ones cut in close up to a point, the stronger the growth at the bottom, where it is most wanted to be, and this will proportionately check the natural tendency in the top branches to out-grow and leave those near the base weak. The too general practice in cutting garden hedges is just the reverse of this; for they are often left to grow to a considerable height; the sides are then cut perpendicularly, and the top flat. Than this it would be difficult to imagine a worse shape to which a hedge could be cut, as it tends to encourage strength in the top and weakness at the bottom. Hedges are usually better managed in the north than in the south; but, even where best managed, utility is often partially sacrificed to appearance by not allowing enough breadth at the bottom. The best and most impervious hedges I ever saw have been composed of Thorn or Holly, 6 feet through at the bottom, and 5 feet in height. The sides of these, which were slightly rounded, ran up to a sharp point at the top. Thus managed, the bottom branches become strong right down to the ground, and so close as to be proof against even poultry. Hedges that have been mismanaged by letting them assume a shape incompatible with the object for which they have been planted, should at once be cut into the required form, using a saw for the strongest branches, and a sharp hook for the weaker wood. When using the latter tool, always cut upwards in a slanting direction, so as to make a clean cut, and do not leave the branches when severed in a jagged split state—a condition that will inevitably occur, if the wood is cut downwards; the superiority of upward cutting will be apparent in the much stronger growth that will be made; hedges that have been allowed to grow to a height of 10 or 12 feet, and which have got naked in the bottom, can thus, by judicious management, be brought into good form. All hedges composed of deciduous plants, such as Thorn or Beech, ought to be operated on immediately. Where Holly, Yew, Laurel, or any other evergreen plants are used, whatever cutting is required, either in the shape of annual trimming, or considerably reducing their size, had better be deferred until the end of March or beginning of April. Young Thorn hedges, that were planted a year ago, should now be cut right down to within 6 inches of the ground, and kept during the summer thoroughly clear from weeds. If the ground has not been well prepared previous to planting, 2 or 3 inches of rotten manure should be "pointed" into it, a couple of feet in width from the collar of the plants at each side, and if tan can be readily obtained, 2 inches spread over the surface will effectually keep down all annual weeds, as well as promote growth by acting as a mulching during dry weather. Hedges that have been planted two or three years should each winter be cut well back to within 9 or 10 inches of the point to which the shoots were shortened the season previous; if allowed to run up too quickly, the inevitable result is thin open growth, ineffectual for either fence or shelter. Few things give a more finished appearance to a garden than well-managed hedges, and for shelter in exposed situations their importance can scarcely be over-rated.

Kitchen Garden.—When the ground is frozen manure should be got on, as during hard weather this kind of work can be done without cutting up the walks by wheeling over them; and also, when in this condition, receives less injury from treading on it than it otherwise would do. Where the soil is of a heavy, retentive nature and much infested with slugs, it will, if vacant, be much benefited by being broke up 6 or 8 inches in depth when frozen. This can be easily done by an ordinary pick, leaving the lumps as rough as possible, so that the frost may effectually pulverise them as well as reach the substratum.

Conservatories.

Camellias expanding their blooms should be freely assisted with manure-water whenever the soil shows that they are in a condition to receive it. Whenever water is used, it should always be given in sufficient quantities to penetrate the whole of the soil in which the plant is growing, so as to thoroughly soak it and run freely through to the drainage. Nothing is worse than frequent dribbles, by which only the upper part of the ball becomes wet and closed against air, while the lower portion, in which the principal feeding roots are, may be perfectly dry. Therefore give a thorough soaking, and then wait till the soil becomes moderately dry before watering is repeated. If this were more attended to, the difficulties experienced by many in keeping plants in good health would quickly disappear. Early flowering Heaths, such as *hyemalis*, *gracilis*, *melanthera*, and others,

now going out of bloom, should have the strongest of the shoots that have borne flowers cut back to within an inch or so of the old wood. Any young growth not over 2 or 3 inches in length should be left entire, after being carefully picked over, in order to remove any decaying flowers or seed-pods remaining on the tops of the shoots. The plants should then be placed where they can enjoy a little warmth and a genial moist atmosphere, so as to induce them to make free growth, with which to furnish a good head of bloom. Any *Epacris* that have done flowering should be treated in the same way. *Cyclamens* and *Primulas* will now be at their best, and of these seedlings are sure to show great variety, both of form and colour. The best of each kind should, therefore, be selected for seed-bearing purposes; and, to ensure the flowers setting, the plants should be placed on shelves near the glass, where they can get plenty of light and air. In the case of choice *Primulas*, it is sometimes best to fertilise them artificially, as the flowers are apt to fall before the pollen becomes distributed. A little timely attention in this way with a camel's-hair brush, ensures the flowers setting well. In watering *Primulas*, see that the crowns of the plants are not wetted, as that induces damping off. Continue to introduce into heat a few plants of the different subjects employed for supplying cut flowers or for other decorative purposes. Maintain a thoroughly moist atmosphere, with a uniform temperature of about 55°, advancing the same 10° or 15° whenever the sun favours an increase. Such plants as the beautiful feathery *Spiraea japonica* and the *Eupatoriums* can scarcely be over watered, and should at no times during their growth be allowed to become dry at the roots. The beautiful little *Azalea amœna* is a capital subject for forcing, as it requires but little artificial heat to get it in bloom early, and, when in that condition, it is one of the brightest and most enduring plants which we possess. Among large-flowered varieties, *Pauline Mardner*, *Flag of Truce*, and the old *Fielder's White* force best. The two former are double, and therefore very lasting when gathered for single blooms for mounting, a purpose for which they are very valuable.

Stoves.

Plants now going out of bloom, such as *Sericographis Ghiesbreghtiana*, *Cyrtanthera magnifica*, and others, should now be kept dry at the roots, in order to induce a slight hardening of their soft sappy stems previous to cutting them down. There is, perhaps, no other plant so generally useful as the *Sericographis*, as it supplies an abundance of brilliant flowers during the duldest months of the year; and, although requiring a cool stove, or intermediate house, up to the period of blooming, it will then stand anywhere in a temperature above 40°, and last in good condition for at least seven or eight weeks. Anyone having supplies of flowers to keep up during the winter should not fail to propagate and get up a stock of this useful plant. Cuttings put in now, or as early as possible, will, with proper care, make good flowering plants by next autumn. The *Cyrtanthera*, too, is an exceedingly useful winter-blooming plant, and, with a little management, may be induced to flower at almost any season. By keeping a few plants, and cutting one or two down at intervals, as they go out of bloom, and then shaking them out and re-potting them when they break, a regular succession of bloom may be kept up. This plant appears to have quite superseded the old *Justicia carnea*, which it greatly resembles; but it flowers with much more freedom. Where plants are required for table decoration, the useful old *Tradescantia zebrina* should not be overlooked, as it can be kept to any size, and in the smallest of pots, while it is always in good condition and ready for use. Any that are becoming leggy through losing their under-leaves may at once be decapitated, reserving the head, and a couple of inches or so of the stem, which, if potted, will soon strike root and be serviceable again. That gem among white flowering plants *Eucharis amazonica* should, where convenience exists for so doing, be plunged in bottom-heat of from 70° to 80°, and should receive plenty of tepid manure-water while making its growth, and producing its bloom. After this is over, keep it moderately dry for a time, lift the pots out of the plunging material, and set them on its surface, so as to afford a season of rest; then reduce the ball, and re-pot in good rough lumps of peat and loam, intermixed with a little sand and well-decomposed manure, the latter scattered over the crocks. Start the plants again in a brisk heat as before, and as soon as they get a good hold of the soil water them freely, but till then rather sparingly. Treated in this manner, they may be induced to flower several times during the year and be none the worse for it. *Allamandas* and all plants of that kind not in active growth should at this season be kept as dry at the roots as is consistent with their safety, as they will start much more vigorously when the time arrives for their doing so, after having been properly rested; and when kept dry they may be wintered in a much lower degree of heat than they should otherwise be subjected to.

Numbers of plants of all descriptions get their roots killed or injured during the winter through too copious watering; and it cannot be too strongly impressed on inexperienced plant cultivators how necessary it is to be careful as to the way in which plants are watered at this season, when the leaves take up so little and root action is sluggish. Gloxinias and Achimenes that ripened off early may now be started by giving them an occasional watering, just to keep the soil moist. Tubers of the latter are best picked out from the old ball, as it is difficult to do so after starting without injuring the young shoots. Place the small tubers thickly in pans of sandy leaf-soil, and put them where they can get a good bottom-heat. Take advantage of the inactive state of most plants just now to extirpate that worst of all insect pests, mealy bug. It increases with marvellous rapidity in spring, and strong measures should now be used to get the plants thoroughly free from it, as the task of doing so later on is almost hopeless. Remove every stick and tie that has the least appearance of harbouring insects. Scrape a few inches of the old tan or other plunging material off the surface of the bed, and remove the same in case of any having fallen amongst it. Keep the temperature as low as the occupants will safely stand, so as to prevent growth taking place during the present short days.

Ferns.

Where these are planted out in pockets, in imitation rock-work, it often occurs that a considerable settling or shrinking of the soil takes place owing to the difficulty of firmly filling the many intricate crevices behind the rock. A close examination should now be made, in order to see if any cavities exist between the rock and soil from the cause just named, for if these remain unattended to, the water effects its escape without passing through the soil or in any way benefiting the plants. Before filling these in, the sides adjoining the rock should be well probed in order to discover if there is any hollow parts behind. Should cavities be found, the soil should be well pressed back, using a blunt-pointed stake or some suitable tool for the purpose. Unless the pockets are of large size, the principal feeding roots will have found their way to the surface of the rock forming the walls of the pockets, and, therefore, great care must be exercised in ramming in fresh soil that these do not become injured. Before proceeding with this work, it will be well to look round and decide if any improvement can be made by a re-arrangement of plants, as a season's growth in the case of some of the stronger varieties greatly alters their appearance and renders them unsuited for the positions originally allotted them. When this is the case, the present is a good time for carrying out any alterations of that kind, as, with a little care now, when they are at rest, they will scarcely feel, so to speak, their removal. Ferneries, arranged in the natural style, are greatly improved by introducing a few plants of bold and distinct foliage that will associate well with the fronds of the Ferns. Of these, Palms are, perhaps, the best, but there are many others that may be used with excellent effect, and none more so than Begonias of the Rex type. Some plants of these in the Fernery here measure over 5 feet across, and have leaves of great size, and richly marked. These stand during winter in a temperature that rarely exceeds 45°, and one which is more frequently below 40° than above it. Therefore, anyone having the coolest of Ferneries may introduce Begonias into it with safety. They delight in the shade and moisture necessary for the cultivation of Ferns, and there are few other positions in which they can be used with such good effect. The much neglected *Aspidistra* and New Zealand Flax are two other plants that have a pleasing effect in certain positions in Ferneries, as, for instance, near rocky recesses containing water, where the leaves of the Flax drooping over the water has a very natural appearance.—J. SHEPPARD, Woolverstone Park.

Indoor Fruit Department.

Vines.—Now is a good time to start a second Vinery, to succeed that started in November. If the Vines were thoroughly cleaned and tied up when pruned, they may now be left undisturbed, except in the case of young Vines, or where hard forcing is contemplated. When more equal, breaking will be effected, laying them along the front of the upright sashes; but where there is no hurry, and the young Vines not too long pruned, laying them down may be dispensed with, and slow forcing will add to the general health. If means exist for getting at the roots, most of which will be found in the outside border, assist them by opening up the inside border at the back wall, removing the soil carefully down to the drainage. If no roots are found there, work forwards with a steel fork until you extricate a few of their points, finishing off with a straight face. Then run a turf-wall along, 18 inches distant from the roots just liberated, and fill up between that and the roots with a compost suitable to the well-being of the Vine. The space behind may be filled up with a mixture of newly-gathered leaves and litter from the stables, put in

firmly, covering the whole carefully with soil. This fermenting matter will retain its heat for twelve months; the roots will run freely in the new soil, and enjoy the heating material. Water the border thoroughly and carefully with tepid water, and cover it up with a bed of fermenting material, consisting of leaves and stable manure, mixed together. The house should then be kept close, and the Vines frequently syringed during the day time. During mild weather, little or no fire-heat will be needed for a time. Take, however, all due advantage of both sun-heat and that arising from the fermenting bed, which will just now be found to keep the house over 50° at night, and higher during the day. Should the weather become colder, apply fire-heat by day only. In early houses, in which the production of fruit is of more importance than the health of the Vines, as soon as thinning has taken place, let them be pushed sharply along by day, shutting up early in the afternoon with as much sun-heat as possible, and a moderate amount of warmth by fire-heat, but allow the night temperature to fall below 65°, giving a little front air if the weather is at all favourable. Attend strictly to pinching, tying, and the regulation of the young wood, and thin as soon as the berries are properly formed. In houses in which the Vines are in bloom give air freely, but avoid currents. If the Vines consist of Hamburgs or other free-setting sorts, they will set their fruit thickly without any atmospheric change. Carefully examine Grapes still hanging for decayed berries, and on a dry day give the house a little smart firing, with plenty of air to expel damp. This will not now be often needed, as the worst season for damping is over.

Peaches.—In early houses let fire-heat be applied cautiously; admit air on all suitable occasions, but avoid draughts. During dull weather keep up a dry atmosphere in houses in bloom, assisting the latter to set by means of a camel's-hair brush used in the middle of the day, 55° should not be exceeded at night until the fruit begins to swell. In late houses, prune, wash, and clean the trees, in such a way that not an insect is left on them. For this purpose, I only use soft soap. Let all be tied up neatly, top-dress the border outside with good rich loam, and water the inside border; commence forcing with a low temperature, say 45° at nights, syringing frequently during the daytime, and shutting up as much heat as possible in the afternoon.

Figs.—Where early fruit is in demand, and where Figs in pots are started with the early Vines, Figs will now be partially shaded by the foliage, and where that is the case, they should be at once removed to lighter quarters, in which a temperature of from 55° to 60° is maintained. Stop all points after the fourth leaf has been made. Thin out the fruit where thickly set, and endeavour to prevent dropping. Syringe them well twice daily, and water freely with tepid liquid manure. Maintain a bottom-heat of from 75° to 80°, and an agreeable humid atmosphere. Start a Fig-house now where more than one is at command—that is if the trees have been thoroughly cleaned, properly tied up, the border well top-dressed, and the usual preparations made. Let the border have a thorough soaking with tepid water, and the syringe should be used freely during the day.

Strawberries.—Plants of these started early will require a temperature of from 55° to 60°, but the latter point should not be exceeded until the fruit is set, when 5° more may be given with advantage. Water liberally with tepid manure of about the same temperature as that of the house. Plants for succession should be introduced into heat according to the demand. Examine the drainage, remove all discoloured leaves, stir the surface of the soil, and shake off that which is inert; re-place it with a rich loam, place the plants near the glass, and never allow them to become dry. Commence forcing with a night temperature ranging from 45° to 50°, allowing a rise by day in accordance with the state of the weather.—J. HUNTER, Lambton Castle.

Hardy Fruit.

As soon as the weather and the state of the ground will permit, planting should be proceeded with and completed with as little delay as possible. Also the renovation of fruit-tree borders, that are in a poor or otherwise unsatisfactory state; badly or undrained soil, too light or dry soil, and deep planting, are the three principal causes of failure in fruit culture, and these should not be lost sight of in any attempts at resuscitation. In the case of retentive or clayey soils, drainage is of the first importance, and they may also be made lighter and opener by the addition of coal ashes, charcoal, burnt vegetable refuse, and lime scraps, all of which are beneficial to fruit trees. On light or dry soils chalk is invaluable, being a retainer of moisture, and for the production of good stone fruits on such soils it is a necessary ingredient. Light soils should also be firmly trodden down; and, immediately over the roots, the surface should be kept constantly mulched with manure, particularly in the summer season. As to planting the "collars" of the stems, when the soil is settled about them, should never be more than about an inch in the ground. Any sickly or failing trees in old orchards should not be suffered

to remain, but be at once grubbed up, and the ground prepared for young trees, by taking out the old soil to a depth of 3 feet, and at least 9 feet in diameter, and replacing it with the best maiden loam procurable. Others that are in good health, but which produce inferior fruit, will be benefited by having the surface soil removed and fresh material applied, putting over that a coating of rotten manure. Gooseberries and Currants are frequently grown under the shade of other fruit trees, and, though in such positions they rarely prove quite satisfactory, yet, with rich annual dressings they may be made to thrive tolerably well, and such dressings should be applied now, either by first forking over the surface of the ground and spreading the manure afterwards to be washed in by the rain, or by lightly forking the manure into the soil. Of these two modes the first is best. All kinds of small fruits may now be pruned; Black Currants produce the most and finest fruit on the young growths of the past season; therefore, in their case, remove as much of the old wood as possible, and thin the young shoots out sufficiently to avoid their chafing each other. For Red and White Currants, "spur" pruning answers best, though it is advisable to leave a few new growths yearly to take the place of any that require removal through the long accumulation of ugly spurs. Gooseberries, though they bear the finest fruit on the new wood of the previous summer, are kept best in bounds by "spur" pruning; and, owing to the buds being so liable to the attacks of birds, by the adoption of "spur" pruning there are usually plenty left for a crop after a good thinning out, whilst buds on the new growths are generally cleared. The pruning and dressing, and, where necessary, also the planting, of outdoor Vines should be no longer delayed. Some planted here two years ago have made growth equal to that of those under glass, and doubtless, from present appearances, will yield equally good returns. Intending planters will find the following kinds best adapted for outdoor culture, viz., Black Hamburgh, Cambridge Botanic Garden, Esperione, Royal Muscadine, and Dutch Sweetwater.—W. WILDSMITH, *Heckfield.*

CUTTINGS BY POST.

WHAT are known as soft-wooded cuttings, that is, cuttings of such plants as Fuchsias, Verbenas, Pelargoniums, Dahlias, and other

Packing Cuttings in Moss and Tinfoil.

popular florists' flowers, are often sent through the post in spring at a few hour's notice, and the best mode of packing for such journeys may be worth attention, in order that the cuttings may arrive fresh and ready for inserting in sandy soil or in a bed or pot of moist heated sawdust surfaced with sand, at once with a sure knowledge that they will strike root and grow. There are several ways of packing cuttings for carriage by post, but that here represented has much to recommend it. In this case the newly-cut slips or branches are laid on a bit of fresh living Moss, moistened in water and squeezed partially dry; the whole is then encased neatly in a piece of sheet lead or tinfoil, which retains its position without tying, and prevents the Moss from becoming dry through evaporation. For packing in large boxes only the lower half of the cuttings need be enveloped, as shown in our engraving; but, if only one little bundle is to be sent, use more Moss and envelop the cuttings entirely, both in that and the tinfoil. A small tin or lightly-made wooden box is admirably adapted for "mailing" cuttings. Such boxes are generally sufficiently strong to

resist crushing or jamming on the journey. Bundles of cuttings packed in damp Moss, enveloped in sheet india-rubber, and finally wrapped in two or three folds of stout brown paper, also travel safely. In cases where a few cuttings have to be carried home in the hand nothing beats Moss and brown paper as packing material.

B.

HOW FLOWERS ARE FERTILISED.*

We may regard a plant—and it is indifferent for our purpose whether we take the smallest weed or the stately forest tree—from two points of view. We may consider only its own individual life, and the parts of the plant, or organs, as they are termed, whose object is the maintenance of this life. With these organs, however—termed, for the sake of distinction, the vegetative or nutritive organs, and comprising the root, the stem, and the leaves—we have at present no concern, interesting as is the study of the structure by which they are adapted to their end. The other point of view is not the individual life of the plant, but the means with which it is furnished for perpetuating the race—for raising up new individuals after it has itself run its allotted term of life. The parts which are specially contrived for the purpose of effecting this object are called the organs of reproduction, and are those included under the ordinary term, the flower of the plant. A flower is, therefore, a complex organ, or rather an assemblage of organs, all having for their final purpose a certain process—which it is our purpose to consider somewhat in detail—known as the process of fertilisation. But before doing so I must describe in botanical language the various parts or organs of which a flower consists. If we look at an ordinary flower from the outside, the part which is first brought under our notice is a kind of cup, generally, but not always, green, which is called the calyx. Before the flower opens, when it is in the bud-condition, this cup envelops the internal parts of the flower, which are then in the process of development, and protects them from injury by any external agency; and the main function or purpose of the calyx may, therefore, be considered to be one of protection. Within the calyx is the most conspicuous part of the flower, generally, but not always, brightly coloured, which is called the corolla. The main function of the corolla is, by means of two properties which it ordinarily possesses—colour and scent—to attract insects to the flower for a purpose which we shall understand presently. Within the corolla come a number of bodies generally differing altogether in shape and appearance both from the sepals, or parts of which the calyx consists, and the petals, or parts of which the corolla consists, and ranging in number from one or two to a larger number than can be easily counted, the stamens. Now, while the calyx and corolla are of subordinate importance, as we shall presently see, in the construction of the flower, the presence of one or more stamens is absolutely necessary to ensure the reproduction of the plant. Each stamen consists of two parts, the filament or stalk, and the anther; the latter only being the really essential part of the stamen. The anther is a bag containing a quantity of very fine dust known as pollen, one of the two bodies which unite to bring about the process of fertilisation. Lastly, within the stamens, occupying always the centre of the flower, is the last of the reproductive organs of which it is composed, the pistil, which again assumes very different forms in different flowers. The pistil consists, in its most perfect form, of three parts: the bottom part is in the form of a bag or hollow receptacle, and is called the ovary, because it contains a number of minute egg-shaped bodies, the ovules; rising from the apex of the ovary is a stalk-like part, the style, surmounted at its summit by a body of very peculiar structure called the stigma, the purpose of which we shall have to examine presently. When the flower withers, the greater number of the parts which we have now been describing disappear, especially the corolla, the stamens, the style, and the stigma, and nothing is left except the ovary, sometimes surrounded by the persistent calyx. The ovary now grows and develops into what is commonly called, when mature, the seed-vessel, or more often, in botanical terminology, the fruit; and the seed-vessel or fruit contains the seeds, which are the mature or ripened ovules, just as the seed-vessel is the mature or ripened ovary. But the change from ovule into seed is not one of growth merely, but is dependent on the formation within the ovule of a body called the embryo; and this embryo can only be produced by the operation of the perfectly definite process which we have now to examine in detail—the process of the fertilisation of the ovule. If an ovule, at the time when the plant is in flower, is examined minutely under the microscope, it is found to consist almost entirely of cellular tissue, i.e., of a number of minute sacs called cells, placed side by side in close juxtaposition, which form the nucleus of the ovule. These are usually enveloped in two coatings of firmer texture, an inner and an outer one, called the secundine and the primine. These two coatings are, however,

* A Lecture by Alfred W. Bennett.

not continuous over the apex of the ovule, where they leave an open channel, called the foramen or micropyle, communicating with the nucleus, and with a large cavity within it which is known as the embryonic sac. In by far the majority of plants the ovule does not, however, retain the position here indicated; but becomes inverted in the course of its growth, one side growing more rapidly than the other, so as to bring the opening or micropyle into close proximity to the placenta, as the point of attachment between the ovule and the wall of the ovary is called. If we now examine closely under the microscope one of the grains of the pollen contained in an anther, we shall find that it also has a somewhat complicated structure. Outwardly these grains vary greatly, both in form, colour, and size. Generally spherical, they are sometimes oval; or triangular, as in the *Fuchsia*, or Evening Primrose; or covered with minute spines, as in the Hollyhock, or Aster. They also are found to be hollow bodies, containing an oily fluid, in the inside, protected by two coats, an inner and an outer one, called in this case the intine and the extine. At one or more points of its surface the extine is weaker, and allows the intine to be seen through it. When the anther is ripe and discharges the pollen, a certain portion of it falls on the pistil, and on that portion of it at the summit of the style which we have called the stigma. The stigma is always distinguished by producing on its surface, at some period or other, a sticky glutinous fluid which causes the pollen grains to adhere to it. This is not the only effect on the pollen grains, of the viscid secretion of the stigma; it excites, by some unknown power, the development of the intine, or inner coating of the pollen-grain, which bursts through the extine, or outer coating, at the weak places I have already described, and protrudes in the form of a tube. This tube, called the pollen-tube, penetrates the loose cellular tissue of the style, grows with astonishing rapidity, and sometimes to an extraordinary length (in the common spring Crocus the style is sometimes several inches in length), through the wall of the ovary, the cavity of which it finally enters. The end of the pollen-tube now, so to speak, seeks out an ovule. From the position of the ovule being, as I have described it, usually inverted, the opening, or micropyle, is not far from the wall of the ovary. This micropyle, the pollen-tube enters, passing through the cellular tissue of the nucleus; enters the large cavity which I have described as the embryonic sac; there finally its end gives way, and the contents of the pollen grain are discharged into the embryonic sac. This is a brief summary of the process known as the fertilisation of the ovule, without which it is impossible for fertile seeds to be produced. Its immediate consequence is the formation within the embryonic sac of a body called the embryo, which at once begins to grow rapidly at the expense of the tissue of the nucleus, the whole of which it frequently absorbs. It is the presence of this embryo that constitutes the difference between the unfertilised ovule and the fertilised seed, and on it depends the power of the seed to germinate and to produce new individuals like unto itself.

Fertilisation of Dioecious Plants.

The contact between the pollen and stigma as carried out by Nature is not quite so simple as would be inferred from the description I have hitherto given. I have at present spoken of flowers as if they always contained both a pistil and one or more stamens. And in the greater number of flowers with which we are familiar this is the case, but not in all. In the Melon, for instance, the Cucumber, and other plants belonging to that tribe, some of the flowers are male, *i.e.*, possess stamens, but no pistil; while others are female, *i.e.*, possess a pistil, but no stamens. Each flower is, as it were, the complement of the other. In these cases it is obvious that the pollen necessary for the fertilisation of the ovule must be conveyed by some foreign agency from the male to the female flowers, which are in this case borne on different plants. Hybridisers generally do this artificially; but we shall see presently that Nature herself supplies a means. This fact in natural history was known as long ago as the time of Herodotus, who describes the process of capriciation, *i.e.* the transference of the pollen, by which a crop of Dates was ensured on the Egyptian Palm trees, from the male to the female trees. Another instance of this is in the case of the *Ancuba japonica*, or, as it is commonly called, the variegated Laurel of our gardens and shrubberies. This plant was introduced into this country many years ago from Japan, by the Dutch. The *Ancuba* is also one of these dioecious plants as botanists term them, in which the same individual bears only male or only female flowers, and the plant first introduced happened to be a female one. Since it did not bear seeds, the only method of propagation was by cuttings; and till within the last few years the whole of the innumerable *Ancubas* throughout the country had been obtained in this way, or, in other words, were but separated parts of the original individual. Plants reproduced in this way can only repeat the characters of the parent plant; every spring, therefore (about March), we might see our variegated Laurels bearing their small purplish female flowers,

but never by any chance producing seed. Not many years ago, however, male plants were also introduced by Mr. Fortune; the female flowers were fertilised, and bore seeds, which being sown produced new plants, some female and some male. The pollen of the *Ancuba* is now an article of trade in Covent Garden Market, and we may frequently see the shrubs ornamented with their bright red berries. Another instance of an unisexual but not a dioecious plant—for, in this case, the male and female flowers are borne on the same plants—is furnished by the common Hazel, on which, moreover, the two kinds of flowers are so different that if you saw them, you would hardly believe that they had anything whatever to do with one another. The male flowers are, in this instance, the familiar yellow catkins which come out soon after Christmas, and remain on the tree for a few weeks, when they drop. Each catkin contains a very large number (perhaps 100 to 120) of such flowers; each male flower consists of ten to twelve anthers, and each anther contains an innumerable number of very fine light powdery pollen-grains. The female flowers are seen on the same branches in the form of minute bright threads, which are, in fact, the stigmas, the ovaries being concealed beneath a number of scales at the base. Some of the pollen-grains fall on the stigma from the catkin, push out their pollen-tubes, and fertilise the ovule in the ovary, which then develops into the nut. But one of the most beautiful examples of the mode of fertilisation in these unisexual plants is seen in a little water plant, the *Vallisneria spiralis*, a native of the south of Europe, grown very commonly in fresh-water aquariums, and affording a very beautiful object under the microscope, to illustrate the continuous circulation or rotation of the contents of the cells of which the leaves are composed. The *Vallisneria* is, like the *Ancuba*, dioecious. The flowers of the male plants are borne on very short stalks, which do not raise them too near the surface of the water. The female flowers, on the other hand, are supported on the ends of very long stalks, which are curved into a corkscrew-like spiral, and are elastic. Submerged when in a young state completely beneath the water, when the pistil is in a condition for fertilisation, the spiral coil relaxes so as to bring the flower to the surface. About the same time the male flowers break off from their short stalks and rise to the surface; they move about for a time as if seeking the female flowers, at the same time discharging their pollen, some of which reaches the stigmas and fertilises the ovules. After the fertilisation is effected the coil of the stalk of the female flowers again contracts so as to bring the flower beneath the water, where the seeds are matured. This illustration introduces us incidentally to one of the most curious chapters in the more scientific departments of botany, that of the spontaneous or quasi-spontaneous movements of plants.

Hermaphrodite Flowers.

It will be seen from these examples that some means are necessary, in the case of those plants where the stamens and pistils are in different flowers, or even on different individuals, for the conveyance of the pollen from the one to the other. It might be supposed, on the contrary, that in perfect or "hermaphrodite" flowers in which both kinds of organs are present, the process would be a much simpler one, and that the pollen has nothing to do but to fall out of the anther on to the stigma in order to effect fertilisation. It was pointed out, however, as long ago as the close of last century, by one of these keen observers of Nature with whom that period abounded, Karl Conrad Sprengel, that the structure of a large number of flowers was such as to render this simple arrangement impossible. But the fact appeared to have been altogether lost sight of until attention has again been called to it, within the last few years, by a number of naturalists, among whom may be mentioned especially Hildebrand and Hermann Müller, in Germany; Delpono, in Italy; and, above all, Darwin, in this country, who has reduced the observed facts to a scientific law. A number of experiments, conducted with a patience and a philosophical power of observation which cannot be too highly praised, led Darwin to the conclusion that when a flower is self-fertilised—*i.e.*, when the ovules are fertilised by pollen from a stamen belonging to the same flower—the number of seeds produced is smaller, or their vigour is less, than if it is cross-fertilised—*i.e.*, impregnated by the pollen conveyed from a stamen belonging to some other flower of the same species; and that if this process of self-fertilisation is continued through several generations, the plant at length becomes altogether sterile. This fact when fully established experimentally, Darwin crystallised into the aphorism now so often quoted, that "Nature abhors perpetual self-fertilisation." Now for the facts: they are patent even to the most careless observer. In unisexual flowers it is obvious that cross-fertilisation must always take place, and even in hermaphrodite flowers we shall find that the same rule must necessarily prevail in most cases. If we take any flower belonging to the genus *Campanula* (as the Harebell, the Canterbury Bell of the gardens, or large wild Bell-flower

of our hedges), and examine the structure of the flower when it is fully open, we shall see that the end of the style is divided into three conspicuous white stigmas covered with little papillæ, which indicate that they are in a receptive condition, *i.e.*, a state in which they are able to excite the protrusion of the pollen-tubes from the pollen-grains. When we look for the stamens, however, we shall find that the anthers have completely withered up, the pollen having been, in fact, discharged from them almost before the flower expanded—at all events, long before the stigmas had opened and exposed their papillæ. It is, therefore, almost impossible that any of the pollen can have fallen on the stigmas; and, if further examination is made, the pollen will be found collected in enormous glutinous masses on the hairs which clothe the lower part of the style. What then becomes of it we shall see presently. The same phenomenon is exhibited by the Pink, the Sweet William, the Stitchwort, or any other plant belonging to the Natural Order Caryophyllaceæ. Before the stigmas in plants of this order—sometimes three, sometimes five—are expanded, the anthers, which hang loosely suspended at the end of the filaments, have dropped off them and completely disappeared. Exactly the reverse is the case in a common roadside weed, the Rib Grass, or *Plantago lanceolata*. Here the flowers grow in a dense spike; in those which are just opening the stigma will be seen protruding like a fine feather from the calyx and corolla, but there will be no appearance of stamens. Examine the same flower at a later period, and you will find the stigma entirely disappeared; and then the stamens are protruded from the calyx and corolla, delicately poised, like in the Pink, at the end of long slender filaments. In a large number of flowers, indeed, the structure of the flower is such as to indicate that the parts are specially contrived so as to exclude the possibility of self-fertilisation. This is very well illustrated in the case of a beautiful flower common in the Lancashire bogs, and in the mountain districts of Cumberland and Westmoreland—the Grass of Parnassus, or *Parnassia palustris*. Five stamens, in this instance, surround the conical pistil, and are mature considerably before the stigmas are developed. The stamens are developed in succession one after another. As each ripens its filament lengthens, and it places itself right on the top of the stigma with its back to it, and the pollen is then discharged from the anther on the side away from the stigma, so that it is scarcely possible for any to fall on it; and this is done by each of the five stamens in succession. In the All-spice tree, or *Calycanthus*, a scented tree, flowering in the winter, we have a very similar contrivance for preventing the pollen from falling on the stigma of its own flower.

Transport of Pollen by the Wind.

From what has just been said it will be obvious that if the pollen is not intended, as a rule to fertilise the ovules in its own flower, some arrangement must be necessary for carrying it from flower to flower; and these are the arrangements for effecting cross-fertilisation, and about which so much has been written of late in botanical works and popular treatises. The arrangements for this purpose may be classed under two heads—those dependent on the wind, and those dependent on the visits of insects. In the Hazel, the structure of the flowers of which has already been described, we have a very good instance of fertilisation by the agency of the wind. Everything here favours the dissemination of the pollen by the least breath of air. The catkins are lightly hung, so as to be swayed by every passing breeze; the pollen consists of very light dust-like grains, and the quantity of it is prodigious. The flowers also appear before the leaves are expanded, so that there is nothing to prevent the pollen being carried in all directions, and some must inevitably fall on the female flowers. If, indeed, the red stigmas are examined under a pocket lens, some of the fine grains will almost certainly be found adhering to them. In the Rib Grass, or *Plantago*, again, where we have seen that the anthers are suspended at the end of long slender filaments, the fertilisation is effected in the same manner. These two instances illustrate the law that those flowers in which the wind is the agent for their fertilisation are in general small and inconspicuous, there being no object for their being brightly-coloured. The arrangements of Nature in these cases, it will be observed, are simply such as to favour the distribution of the pollen—its light and dusty character and enormous quantity, and the loose manner in which either the anther itself or the catkin is suspended. The quantity of pollen in some of these unisexual plants is illustrated by the clouds of smoke, as it looks like, which rises from a Yew tree if struck with a stick or violently agitated by the wind at the time of flowering, giving it the appearance of a burning bush. Travellers state that the waters of some of the large American lakes, as Lake Michigan, are covered at certain periods for a considerable distance near the shore by a thick stratum of a viscid sulphur-like substance, the pollen of the Pine forests, which must have been brought by the wind from a distance of several miles. It is generally believed—

though on this point further experiments are still wanting—that our cereal crops, especially Wheat, Rye, and Barley, are fertilised exclusively by the agency of the wind. The flowers are small and uncoloured, without calyx or corolla; the anthers are hung lightly on the end of long slender filaments; the pollen is very fine and powdery; and insects are hardly ever seen to visit them. Favourable weather (fine and sunny with light breezes, and yet not so strong a wind as to disperse the pollen to too great a distance so that it will not perform the purpose for which it was designed) at the time when the plants are in flower—*i.e.* in the early part of June—is therefore of very great importance for the ensuring of heavy crops. But the cross-fertilisation of plants by the agency of the wind is not nearly so common, nor is it a phenomenon so striking or interesting to the ordinary observer, as cross-fertilisation by insect agency.

Transport of Pollen by Insect Agency.

In many flowers the pollen-grains are so heavy, or they are connected together by fine threads or by a sticky glutinous substance, that it would be quite impossible for the wind to effect their transport; and in these cases Nature has recourse to her gigantic army of insect workers to do this service for her. It is in seeking for their own food which consists in a number of classes almost entirely of the juices of flowers, that insects perform this service to the vegetable world; and the modes adopted to allure them are two-fold, the very points which render flowers so attractive to our senses—the beauty of their colour, and the beauty of their scent. That portion of the food of insects which they obtain from the vegetable world is almost always in the fluid state—the sweet juices of plants contained in various parts, but especially the flower. That part of the flower in which this liquid juice or honey is secreted is called the nectary, and occupies the most various positions in different flowers. In the large flowers of the Crown Imperial there is a deep pit at the base of each petal, containing large drops of honey. When the flower is in the form of a tube or bell, the bottom of this tube or bell is very commonly occupied by the nectary, as in the *Salvia*, or very often there is a small nectariferous gland at the base of each stamen. In the *Hellebore* two of the petals themselves are converted into nectaries; in other flowers some of the stamens; in fact, any part of the flower may be adapted to this special function. It is to this sweet secretion that odiferous flowers generally owe their scent; and the very same property which induces us to cultivate them attracts also to them the insects in search of their food. In bright sunny weather our *Mignonettes*, *Pinks*, *Roses*, and other scented flowers may be seen to be visited by swarms of insects seeking nutriment from them. The nectary is frequently too deeply concealed in the flower—since it must be protected against the influence of rain and other injurious agencies—for the body of the insect to be able to be brought near it; and hence those kinds which visit the flowers with long tubes are commonly provided with a long proboscis, as may be seen in butterflies, moths, and bees. But in a very large number of plants which produce sweet juice suitable for the food of insects this juice is not scented at least to our coarse organisations; and in these cases the chief mode of attraction to the insects is the bright colour of some part of the flower, generally the corolla, or when this is absent, occasionally the calyx. We see from this the reason of the law that may, perhaps, have struck some of you, that very brightly-coloured or large, conspicuous, variegated flowers, are seldom scented, while highly-scented flowers are often inconspicuous, or, if coloured, are, at least, not variegated. We may contrast, for instance, the sweetly-scented *Daphne*, *Primrose*, *Sweet Violet*, *Lily of the Valley*, *Rose*, *Hyacinth*, *Evening Primrose*, *Lime tree*, *Mignonette*, *Amaranth*, &c., all with inconspicuous flowers, or, if large and conspicuous, of uniform unvariegated colour, with the brilliantly-variegated but comparatively or quite scentless *Frilligary*, *Pelargonium*, *larger* and smaller *Convolvulus*, *Tropæolum*, *Mimulus*, *Ranunculus*, *Pansy*, &c. We have now seen how the bright colour and sweet smell of flowers aid in attracting to them insects in search of their food; but not yet how this is of advantage to the plant itself. If we notice a butterfly or a bee while rifling the sweets in a flower, we shall see a quantity of pollen dust almost invariably sprinkled over its head or other part of its body. This is independent of the great quantity of pollen which hive and humble bees carry away on their thighs, which they purposely rob from the flowers, and which they take home to their nests, where it forms the "bee bread" which they store up for their young while in the larva state. The arrangement of the parts of the flower, indeed, is almost always such that when withdrawing its proboscis from the corolla-tube, or other part where the honey is secreted, it must necessarily come into contact with one or more of the anthers, and thus carry off some of the pollen, which it lodges on the stigma of the next flower of the same species which it enters. Thus, in those flowers in which the pistil and stamens are mature at different times, the pollen is conveyed from the mature anther in one

flower to the mature stigma in another flower which has opened a little earlier or a little later, and cross fertilisation is thus effected. The vegetable kingdom is full of contrivances for this carrying of pollen, by means of insects, and for rendering self-fertilisation impossible, or at least very difficult. In the *Salvia* the anther is at one end of a cross-bar lightly affixed across the end of the filament, the other end of the cross-bar being unprovided with an anther. When a bee inserts its proboscis into the flower its head strikes against the end of the cross-bar which has no anther, turns it right over, the end of the filament being the fulcrum, and tips the pollen out of the anther on to the back of the insect, and it is thus carried to another flower.

Fertilisation of Orchids.

A very remarkable series of contrivances for effecting cross-fertilisation has been illustrated, with great patience and ingenuity, by Mr. Darwin, in the case of our native Orchids, both the common meadow species and those which grow especially on the chalk hills of our southern counties. Mr. Darwin found that if one of these Orchids is covered over with muslin gauze so as to prevent the visits of insects it never perfects any seed; indeed, the structure of the flower is such as to render self-fertilisation all but impossible. The pollen does not in these plants exist in separate grains, but is glued together into club-shaped masses called pollinia, placed immediately above the stigma, so that they could hardly, of their own accord, come in contact with it. These pollinia are attached to a viscid disc at the base. The Orchids are chiefly visited by butterflies and moths. When one of these inserts its proboscis into the tube of the flower which contains the honey, its head necessarily strikes against this viscid disc, which it detaches and carries away with the pollinia adhering to it. In Darwin's admirable work on the "Fertilisation of Orchids," a masterpiece of experimental research, which every one interested in the subject ought to read, is a drawing of the head of a moth, which he actually captured, with quite a number of these pollinia adhering to it. After the removal of the pollinia a very curious change takes place in their position in consequence of their exposure to the air. After a few minutes' exposure the viscid substance at the disc sets, or becomes hard, and in so doing changes the direction of the pollinia from vertical to nearly horizontal. The result of this is, that when the moth, with one of these pollinia attached to its proboscis, enters another flower, it must necessarily strike the pollinia against the stigma, and thus detach a sufficient quantity of the pollen of which it is composed to ensure the fertilisation of the ovule. All these processes may be followed by removing the pollinia from the flower of any common Orchid by means of a pin or fine pencil, instead of the proboscis of an insect. In *Coryanthes* the contrivance is still more remarkable. "The Orchid has part of its labellum or lower lip hollowed out into a great bucket, into which drops of almost pure water continually fall from her secreting horns which stand above it, and when the bucket is half full, the water overflows by a spout on one side. The basal part of the labellum stands over the bucket, and is itself hollowed out into a sort of chamber with two lateral entrances. Within this chamber there are curious fleshy ridges. The most ingenious man, if he had not witnessed what takes place, could never have imagined what purpose all these parts serve. But Dr. Criger saw crowds of large humble-bees visiting the gigantic flowers of this Orchid—not in order to suck nectar, but to gnaw off the ridges within the chamber above the bucket: in doing this they frequently pushed each other into the bucket, and their wings being thus wetted they could not fly away, but were compelled to crawl out through a passage formed by the spout or overflow. Dr. Criger saw a continual procession of bees thus crawling out of their involuntary bath. The passage is narrow, and is roofed over by a column, so that a bee, in forcing its way out, first rubs its back against the viscid stigma, and then against the viscid glands of the pollen-masses. The pollen masses are thus glued to the back of the bee which first happens to crawl out through the passage of a lately-expanded flower, and are thus carried away. When the bee, thus provided, flies to another flower, or to the same flower a second time, and is pushed by its comrades into the bucket, and then crawls out by the passage, the pollen mass necessarily first comes into contact with the viscid stigma, and adheres to it, and the flower is fertilised. Now, at last, we see the full use of every part of the flower—of the water-secreting horns, of the bucket half full of water, which prevents the bees from flying away, and forces them to fall out through the spout, and rub against the properly-placed viscid pollen masses and the viscid stigma. The construction of the flower in another closely-allied Orchid, the *Catasatum*, is widely different, though serving the same end, and is equally curious. Bees visit these flowers, like those of the *Coryanthes*, in order to gnaw the labellum; in doing this, they inevitably touch a long, tapering, sensitive projection, or, as I have called it, the *stemma*. This *stemma*, when touched, transmits a sensation or vibration to a certain membrane, which is instantly

ruptured; this sets free a spring, by which the pollen mass is shot forth like an arrow in the right direction, and adheres by its viscid extremity to the back of the bee. The pollen mass of the male plant—for the sexes are separate in this Orchid—is thus carried to the flower of the female plant, where it is brought into contact with the stigma, which is viscid enough to break certain elastic threads, and, retaining the pollen, fertilisation is effected." To illustrate the extraordinary variety in Nature's contrivances, it may be mentioned that one species—the curious *Bee Orchis* of our chalk hills—offers a remarkably contrast to this ordinary arrangement. This *Orchis* Darwin has never, after the most diligent research, seen to be visited by insects; and is, must, consequently, be self fertilised. Accordingly, its pollinia are found to be of different structure to those of other members of the family. Instead of standing stiff and upright, they have much longer stalks than is ordinarily the case, which, when mature are flexible, and cause the pollen-masses to hang down in front of the stigma, against which any breadth of wind would cause them to strike, and thus bring about self-fertilisation. It would seem as if different kinds of insects have a partiality for different kinds of flowers, and even for different colours. Plants with very large bell-shaped flowers are fertilised chiefly by large moths belonging to the tribe of sphinxes, and by large beetles of the cockchafer or rosenchafer kind. The largest-flowered of European plants—the *Peony*, the *Rose*, the large white *Convolvulus* of the hedges, and the *Evening Primrose*—are fertilised in this way. The *Evening Primrose*, which opens about sunset, is visited by the largest kinds of night-flying moths, which are attracted from great distances by its delicate scent. The connection thus opened out between the animal and vegetable worlds, and their mutual dependence one on another, is almost infinite. Many plants would appear to depend for their fertilisation on the visits of one particular insect, native to the districts where it grows; and, therefore, if transplanted to another country, or another climate, where this particular insect is not found, although they may flower abundantly, they will not produce fertile seeds. The American *Yucca*, for instance, which flowers with us, but never bears fruit, has lately been found to owe its fertilisation to a particular species of moth, which has its proboscis extraordinarily modified to obtain the nectar from the flowers of this plant only. Many of the exotic plants grown in our gardens, though thriving and flowering freely, are never known to produce seeds, doubtless from the absence of the insects specially adapted to fertilise them. This is the case with the *Yellow Jessamine*, so commonly seen flowering in the depth of winter, a native of Japan, and with the *Galycanthus*, or *All-spice* tree. There is a species of *Orchis* with the nectary of prodigious length (1½ inches have been measured in specimens cultivated in this country), called, from this circumstance, *Angraecum sesquipedale*, which long taxed Mr. Darwin's ingenuity as to the mode by which it could be fertilised, the nectar only occupying ¼ inch of the whole length of the nectary. He predicted, in his "Fertilisation of Orchids," that an insect must exist in its native country (Madagascar) with a proboscis long enough to reach to the bottom of the nectary; and, quite recently, this has been proved to be actually the case.

Insects and Geographical Distribution.

The geographical limits of the natural distribution of many plants are again fixed rather by the distribution of the insects which fertilise them than by the climatic requirements of the plants themselves. Local botanists state that in certain districts of south Lancashire many wild plants are not found, or only very rarely, which are extremely abundant with us in the south of England, such as the *Lamium album* or *White Dead-Nettle*, the *Convolvulus arvensis* or smaller *Bindweed*, the absence of which can only be accounted for on similar grounds, there being nothing in the climate or soil to prevent their occurrence. Mr. Grindon states that the fragrant *Labiates* (very *Labiata*, in fact, that yields powerful odour) are wanting, except *Stachys sylvatica*, and the wild *Thyme* in one or two very rare localities. The *white Dead Nettle*, the *Hound's-tongue*, the *Sweet Violet*, the *Plantago media*, all among the commonest of common plants in the southern countries, are here all but entirely absent. The two common *Mallows* are very rarely seen, the common *Bindweed*, never; the *Cowslip* is extremely local; the *Comfrey* is unknown, as also is the commonest of the wild *Poppies*. On the other hand, some splendid plants, like the *Giant Bell-flower*, *Campanula latifolia*, hardly known in the south, are here very common. As one travels from a more southern clime northwards, one class after another of insects disappear, and with them the plants which depend on them for fertilisation. In Alpine and Arctic countries a number of the native plants, especially the trees like the *Birch* and the *Fir*, have very inconspicuous flowers, and are exclusively wind-fertilised; while others have remarkably brightly-coloured or powerfully-scented flowers, like the *Rhododendron* or *Alpine Rose*, and the

beautiful Soldanella and Gentian, which thrust their brilliant sky-blue flowers, even through the melting snow, to attract from great distances the comparatively rare insect visitors. Every traveller has remarked the brilliancy of the Alpine flora in May or June, or that of a country where the flowering season lasts for only a very few weeks, like Palestine; but few have probably speculated on any other reason for this than the egotistic idea that its only purpose was to gratify the eye of the passing traveller. Darwin, in his "Origin of Species by Means of Natural Selection," gives a curious instance of the mode in which these different forms of life are inextricably intermingled with one another. The common Red Clover is visited and fertilised only by humble-bees, the proboscis of the honey-bee not being long enough to reach the nectar. The number of humble-bees in any district depends in a great measure on the number of field-mice, which destroy the combs and nests. The number of field-mice is again largely dependent on that of cats; and the nests of humble-bees are therefore especially abundant near towns and villages where cats abound. Hence it may be said, without exaggeration, that to our domestication of the cat is due, to a large extent, the possibility of large Clover crops.

Miscellaneous Fertilisation.

The function of fertilising flowers is not absolutely confined to insects in the animal world; spiders and snails also do their part, though to a comparatively small extent. In tropical, and even in temperate America, a large part of this duty is done by humming-birds, which live on the honey obtained from the very long and deep tubes of such flowers as the Bignonia or Trumpet-flower. Some very curious relationships have been drawn out between the length of the beak of each species of humming-bird and that of the tube of the flower from which it chiefly obtains its food. Humming-birds are also said to have a *penchant* for brilliant scarlet flowers, which are very common in tropical countries, while the colour is very rare among the natives of the temperate climates. Among our common wild flowers it would be difficult to name any of this hue, except the Poppy and the little scarlet Pimpernel. But there is another important feature in special adaptation for insect fertilisation on which we have not yet touched; and this refers to the variegation of flowers of which we have at present spoken as being chiefly fertilised by insects of the largest kind have been uniform in colour without any variegation, as the wild Rose, the large white Convolvulus, the Peony, and the Evening Primrose. There are a large number of other flowers, both larger and smaller, which owe their beauty to variegation, that is, to dots and streaks of a different colour to that of the greater part of the petals. It was pointed out as long ago as by K. C. Sprengel, the botanist of last century to whom I have already alluded, that whatever variegated plant you observe, say the Fritillary, the Mimulus, the Pelargonium, or the Pansy, the streaks or dots will invariably be found pointing towards the nectary, or receptacle of honey; and, that, moreover, brightly variegated plants are almost invariably scented. The conclusion was irresistible, a conclusion abundantly confirmed by observation, that the variegation is a guide to insects in search of the food in those large flowers in which the guide derived from odour is wanting. It has also been observed, as might also have been expected, that variegated flowers are very commonly visited and fertilised by very minute insects, by whom such a guide-post is especially wanted. A very instructive lesson in Nature's economy of resource in not supplying, in the same instance, two means to the same end, may be learnt by contrasting a number of pairs of nearly-related plants; in each case one having uniform-coloured scented, and the other variegated scentless flowers, as the Primrose and the Auricula, the Sweet Violet and the Pansy, the Musk and the Mimulus, the Sweet-scented Orchis (*O. Canopsea*) and the Spotted Meadow Orchis, and many others. In the Wild Pansy (*Viola tricolor*) we have a remarkably good instance of the special contrivances intended to aid small insects in their search for honey. The nectary is, in this case, the extremity of two remarkable appendages, which hang down from two of the stamens into the "spur" of the corolla. Of the five petals, the lower and the two side ones have streaks pointing to the orifice in the centre of the flower. When an insect gets inside this opening, it finds it completely blocked up by a ring formed of the five anthers, except just in front, where there is a small opening just large enough to admit its body. Exactly opposite this opening is the thicker end of a wedge-shaped black streak, which conducts the insect right down the style to the very spot where it can reach the nectary. In making the descent, it must necessarily carry off some of the pollen which is discharged from the stamens internally within the ring; and in making the ascent and emerging from the small orifice, it must also, almost inevitably, enter the stigma, which is here a cavity in the upper part of the style, above the ring formed by the stamens. As far as my own observation goes, the Wild Pansy is fertilised only

by the thrips, one of the minutest of insects; but the interesting point is, that both the little opening in the anther-ring and the black streak on the style are wanting in the sweet Violet, where they are not required, and where fertilisation is effected in quite a different way.

THE FRUIT GARDEN.

MELONS FROM MAY TO NOVEMBER.

Now that St. Michael Pine-apples have all but superseded those of English growth, attention will doubtless be turned to some other branch of fruit culture that will be likely to become more popular; and, in this respect, the Melon stands in the foremost rank. At present, however, it is only procurable for a few months in the year, and at a higher price than that paid for Pines at the same season. I am not now referring to the foreign Melons that find their way into our markets. Hitherto, the Melon has not received the same attention at the hands of market gardeners as the Pine-apple; indeed, it is seldom grown for the market by them; but now that they are giving up Pine culture they will doubtless find it profitable to devote more attention to it. Finding that Melons, with us, are always eaten in preference to Pine-apples, so long as they are to be had, I am about to devote what has hitherto been a Pine-pit solely to their culture, in order to extend the supply. This pit produced at the rate of three Pines to the light, which is narrow, and I was well pleased when we cut at the rate of from 10 to 12 lbs. to the light, all over from Queens eighteen months old or more. Now I hope, if I am ordinarily successful, to take two crops of Melons out of this pit between May and November, and at the rate of about 20 lbs., or thereabouts, to the light, which is a moderate estimate, and to have the pit at liberty for other purposes during the winter. With ordinarily fair appliances, the Melon is easily grown—the great point is to get a good variety to begin with. The essentials are a vigorous constitution, a fruitful habit, and good flavour, but it is not often these qualities are combined. When they are, the variety should be taken care of. Many Melons are excellent and high flavoured, which are otherwise worthless for general culture. Gilbert's Victory of Bath and Easton Castle Melons are two excellent kinds as regards appearance, size, and flavour, but they are not prolific. We have constantly grown the Colston Basset ever since it was sent out, testing the new introductions in the meantime as they came out, but none have approached the Colston Basset for general excellence. When it was sent out some years ago, Mr. David Thomson wrote thus of it in a contemporary:—"Were I restricted to one variety I should make choice of it." It has more good qualities than any other I have ever grown." This opinion of it induced me to plant it extensively the following season, and I can say that the character which Mr. Thomson gave it holds good still. It has a good constitution, is an exceedingly free bearer, handsome, well flavoured, and a good keeper. I planted it alternately with Gilbert's Victory of Bath and Easton Castle last summer, and found that it just bore three fruits to one of the other two, and kept its foliage better. The only variety with which I ever could compare it was one called Anstin's Incomparable, which I grew for ten years or more, till it refused to thrive with me. The next best was Queen Emma, a kind belonging to the white-fleshed, yellow-skinned, oblong type, for the stock was not pure. It was an excellent Melon if not permitted to bear too soon, and its constitution was so good that as soon as one crop finished swelling it made a second growth, and set a second crop freely, and sometimes a third. All Melons will do this, I am aware, less or more, according to culture and soil, but few are so generally vigorous and fertile at the same time as the Colston Basset, which shows and sets freely when a foot high, but of course it is not advisable to crop any Melon so soon, except for an early fruit or two. The constant obstacles with which Melon growers meet, and which plague the inexperienced more particularly, are weakly-constituted varieties, and the difficulty of getting a good set of fruit. Many an amateur who superintends his own garden has abandoned Melon culture because he could not succeed in getting more than one or two fruits for his pains all

the summer. It may be stated without hesitation, I think, that the Melons of the present day are not a whit better in flavour than those of twenty or thirty years ago. This is my experience; at least; and, notwithstanding all the new kinds which are continually making their appearance, it is only now and then one gets a variety which deserves perpetuating. The Melon season may be said to extend from the middle of May until the end of November, or to about six months. Melons ripened before the middle of May are expensive productions and inferior in flavour, and the same may be said of those ripened after the end of October or beginning of November. In order to prolong the season to the end of the latter month, the plan is to grow good keeping kinds that will last for a month after they are ripe. I have kept Colston Basset, and some others, for nearly that period in November. In the south and in favoured localities Melons may be had till Christmas, but I am speaking of what is practical generally. To have Melons in May, sow early varieties in January; push them on in a bottom-heat of from 75° to 80°, with a top-heat about the same—70° at night and 80° by day, for example—and keep the plants near the light, but reduce the temperature without fear, especially at night, in severe or cold dull weather. No healthy growth can take place if the temperature and light are not properly balanced. Naturally, the Melon is of sturdy habit, and the foliage is of a dark green hue; but those marks of good health can hardly be expected to be fully developed in early spring, though they should be aimed at. Early crops are frequently ruined by subjecting the plants to too high a temperature. In warm summer weather, when air can always be admitted freely, the Melon may be subjected advantageously to a very high temperature, both root and top, such as would be fatal to its welfare early in the season. Directions which apply to summer crops are, therefore, inapplicable to early ones. For the latter I have proved most satisfactorily, to myself, at least, that the temperatures given above are high enough, on the average, to produce healthy plants and good fruit before June in the case of early varieties; and, to secure fruit from these as soon as possible, the plan is to plant moderately thick, to top the most advanced plants as soon as they are about 18 inches high or so, in order to get a fruiting lateral or two, and to set the first fruits that show. The other plants need not be pushed so hard, but topped in succession, which will cause the fruit to ripen in rotation, and, of course, the later-topped plants, having most wood, will yield the heaviest crops. From four to six fruits to a plant should be aimed at, and a healthy plant is capable of swelling off that number to a presentable size. The lighter the crop the heavier the individual fruits are, but it is seldom or never that three fruits will weigh in the aggregate as much as six. It is best, therefore to look to quantity as well as size. Presuming the early supply lasts from the middle of May to the middle or end of June, it will be necessary to sow the second crop about the 1st of March. The treatment of successive crops is the same as that of the first, except that higher temperatures may be afforded, but 80° in the bed should never be exceeded by fire-heat, and hot pipes should be dispensed with whenever the natural heat economised will sustain it at that figure itself, and 90° should be the maximum for the top, unless hurrying is necessary. Sowings may be continued till the beginning of July or later, according to circumstances, in order to carry the supply into November or December. Much, of course, depends upon variety, mode of culture, soil, &c., and the prospect of getting two or more crops from the same plants; but most growers sow periodically to prevent mishaps, as the seed does not cost much, and the plants are there if wanted. As regards general treatment, much depends on whether the plants are grown on a hot-bed, under a frame, or in a house heated with hot water. In the former case much less watering and damping is needed, but generally speaking it will suffice to say that next to attention is the matter of temperature; as before pointed out, the maintenance of a genial temperature—neither too dry nor yet too moist—and judicious watering at the root are the chief points. While the plants are growing freely, and when the bed is well filled with roots, water should be supplied in abundance, and thin mulchings or top-dressings of good soil applied as the roots are observed on the surface, as the watering lays them bare and they suffer from drought.

Damping overhead is most needed when much artificial heat is used, but in warm summer weather, when the fires are allowed to go out, copious waterings at the root are more than sufficient for all purposes. Ventilation must be attended to, and hardly too much air can be given consistent with the maintenance of the desired temperature. J. S.

When are Oranges fit to Gather for Dessert (see p. 52).—Having at one time a good collection of Oranges under my management, I found that as soon as they reached a deep yellow colour they were fit to gather; and that by leaving them too long on the trees they got spongy and juiceless. The Oranges grown in the open air abroad are, I believe, at their sweetest and best when they part freely from the stalk, being then quite ripe. Your correspondent likewise wishes to know how long Oranges take to ripen from the time the fruit has set, but this can only be known by registering the temperature of the house in which they are grown. The only Oranges I ever tasted equal to those of foreign growth were fruit of the blood variety ripened on the back wall of a Peach-house, where the temperature was very high in the summer months, but cold after the Oranges ripened in November.—WILLIAM TILLEY, *Welbeck*.

French Mode of Training Vines on Walls.—The following is a French mode of training Vines on walls, and a very good one it is; the walls are trellised with split pieces of Oak which last as long nearly as the walls themselves. The Vines are planted against them some 6 feet or so apart, as there are three tiers of Vines, or cordons as they may be termed. The distance for each Vine to run horizontally is something like 9 feet or so; the horizontal shoots are tied to the first bar or lath, and the rest of the space is left for the summer shoots and fruits, and only one bunch of Grapes is left on each pair of shoots. The shoot that fruits this year does not bear fruit

French mode of training Vines.

next, and so on throughout. It is a simple and quick way of covering a wall, and one which in the southern part of England might be advantageously practised.—CHEVALIER.

Paul's Imperial Crab Apple.—Specimens of this very ornamental fruit were exhibited at South Kensington in September, 1874, by Messrs. Paul & Son, of Cheshunt, and a coloured representation of it was given in the January number of the "Florist." It was raised, we are informed, by Mr. Laing, of Twickenham, and is an accidental cross between the Red Astrachan Apple and the Siberian Crab. Its handsome foliage and vigorous habit, coupled with its brilliantly-tinted fruit, have gained for it general favour. The fruit almost declares its parentage, so vividly is it coloured, while the Astrachan Apple blood gives it the quality of being the earliest-ripening of the Crabs. It makes a handsome standard or free pyramidal bush.

Few and Good.—There is much less seeking after mere novelty in fruits in France than in England or Germany, and in France also it is rare that old vegetables are sent out with new names, or that seedsman affix their own names to old kinds. In a German report on the fruit crops, we learn that at Angers, in one of the largest fruit-tree nurseries in France, the following seven sorts only are raised in large quantities:—Williams's Bon Chrétien, Duchesse d'Angoulême, Easter Beurré, Louise Bonne, Beurré d'Amabilis, Beurré Diel, and Beurré d'Arenburg. On an average, from 30,000 to 40,000 trees of each of the two first are sold every year, and about 20,000 of the other five put together. Even the best of the new varieties find scarcely any sale.

Wheeler's Russet Apple.—This is one of the most useful and delicious of dessert Apples from this time until May. Though small in size, and somewhat uninviting in appearance, it has a firm white crisp flesh that is juicy, brisk, and in every way excellent; the tree, being one of moderate growth, is well adapted for small gardens, and it bears abundantly every season.—A.

THE LIBRARY.

ORNAMENTAL CONIFERS, RHODODENDRONS, AND OTHER HARDY SHRUBS.*

This forms one of a series of practical and thoroughly useful "handy books" issued by Messrs. Blackwood. It is exactly what it professes to be—a manual for the amateur and the practical gardener, containing, as it does, selections of the best Conifers and flowering plants of that beautiful group known as American plants, together with many hints and suggestions respecting their propagation and culture. It is a book that will fill a void in many an amateur's library, and, as Mr. Fraser describes his plants according to the way in which they succeed in a latitude as far north as Edinburgh, little doubt, either as to hardiness or utility, need be entertained. Classified lists of select varieties are given where requisite. Taken as a whole, we can confidently recommend this little manual to all who wish to possess a good account of the best and most useful Conifers and American plants now in cultivation. The following extract will serve to show the way in which our author treats his subject:

Erica (the Heath).

Compared with the many hundreds of species and varieties of this brilliant genus, for which we are indebted to the Cape of Good Hope, and which all require greenhouse culture in this country, the European sorts, well known as hardy Heaths, occupy but an insignificant position. They form, nevertheless, a surpassingly beautiful and interesting group of dwarf, free-flowering, evergreen shrubs, easily managed, and worthy of far more attention than has hitherto been bestowed upon them. Of the few species from which the now numerous varieties in cultivation have sprung, the mountains and moorlands of our own country have contributed some of the finest, and they are found in more or less abundance in almost every country in Europe. Growing with the greatest luxuriance in sandy peat, which for the most part forms their natural soil, there are, at the same time, few loams in which they will not succeed, if rich in vegetable matter and free from chalk or lime; while the worst for the purpose may be adapted for their wants by the application of a moderate quantity of peat or leaf-soil, and even a liberal allowance of well-rotted manure, which they all appreciate very much. Several of the showiest sorts—such as the varieties of *herbacea*, *mediterranea*, and *australis*—which flower in the order indicated from February till April, are valuable for winter or spring gardening, and have recently been used with the most admirable results, their neat habit of growth, fresh green foliage, and profusion of bright-coloured flowers, giving a gaiety and effect which no other plants could at that season, and contrasting admirably with the early bulbs with which they are associated. The other sorts—varieties of *tetralix*, *cinerea*, and *vulgaris*—are in perfection from May to September, the one succeeding the other, when *vagas* begins to develop itself, and continues till late in autumn. The smaller-growing sorts make neat edgings to beds or borders, as they may be kept trimmed and neat without disparagement to their flowering. The best way, however, of exhibiting their beauty to its fullest extent is that of grouping them in beds by themselves; and when carefully arranged, according to habit and colour of flowers, nothing can be more attractive. To keep them in health and vigour, it is necessary that they should be lifted every four or five years, and either replaced with young plants, which are easily obtained from layers, or sinking the old plants deep enough to cover the bare stems, which render them so unsightly. This can be done with perfect safety as the young shoots root freely in a few months immediately below the surface. The operation of transplanting may be safely performed at any time between September and April; we prefer, however, the months of February and March, if the weather is open and the ground in good working order, as on the whole the best for the purpose. Most of the sorts are then at rest, and the work is completed before growth commences. Of a large list of species and varieties, the following are the finest and most distinct:

E. australis.—This pretty species is found wild in Spain and Portugal, and was first introduced to this country in 1769. It is a close bushy shrub of about 4 feet high, producing its purplish-red flowers in abundance during the summer months. It thrives best in a sheltered situation.

E. ciliaris, indigenous to Portugal, the south of England, and some parts of Ireland, is a neat dwarf species from 9 to 12 inches in

height. It produces its pale red flowers in terminal racemes from June to July. It is one of the finest of the hardy Heaths.

E. cinerea.—This species is found in great abundance in many of the northern countries of Europe, and all over Britain, rarely rising above a foot from the ground. The flowers are reddish-purple, changing to blue, and begin to expand early in June.

E. c. alba.—Occasionally found in the natural habitats of the species, from which it only differs in having pure white flowers.

E. c. atropurpurea.—In this variety the flowers are deep rosy-purple.

E. c. bicolor.—In this variety the flowers are pale purple, darker at the point.

E. c. coccinea.—Flowers bright red.

E. c. monstrosa.—A curious variety with monstrous flowers.

E. c. pallida.—Flowers bluish.

E. c. purpurea.—Flowers light purple.

E. c. rosea.—Flowers bright rose, a very distinct and beautiful variety.

E. c. spicata.—A light pink variety, the flowers produced in spikes.

E. herbacea, indigenous to a wide area in central Europe, and in some localities in North Wales, is one of the finest of our hardy Heaths. It produces its lovely pale red blossoms from the beginning of March, and in some seasons much earlier, till the beginning of April; it is a magnificent spring bedding-plant, and as it may be clipped freely without damage, it is valuable as an edging in flower gardens. It grows about a foot high.

E. h. carnea.—According to some botanists, this is the type of the species, from which it only differs in having bright red or flesh-coloured flowers; it is also a fine bedding or edging plant.

E. mediterranea.—so named from being found abundantly in the countries bordering the Mediterranean Sea. It is also found in several districts in Ireland. In habit of growth and general appearance it resembles the preceding, which, as has been suggested, is probably only a form of this species. Its flowers are pale red, the anthers of a darker colour, and very prominent, and usually in perfection in April.

E. n. alba.—The flowers of this fine variety are pure white.

E. n. carnea.—Flowers flesh-colour.

E. n. glauca.—In this variety the foliage is glaucous, the flowers similar in colour to the species.

E. n. nana.—A very dwarf form, of a neat, round, bushy habit, well adapted for a small bed, or for edging in miniature flower gardens.

E. n. stricta.—A very distinct variety, with a close upright habit of growth.

E. n. rubra.—In this variety the flowers are of a deeper red than those of the species.

E. Mackaiana.—This species is indigenous to the Continent, and is also found in Connemara, Ireland. It has broad ovate leaves, silvery on the under surface, possibly a variety of *tetralix*; it grows about a foot high. The flowers are pale red, expanding in July and August. It is a remarkably showy plant.

E. multiflora.—Indigenous to the south of France, where it grows to the height of about 2 feet. It is a very distinct and showy species, producing its pale red flowers in great abundance, generally from August to September. It grows very freely, but requires a sheltered situation.

E. stricta, a native of the mountains of Italy, is a very distinct and handsome species, growing to heights of from 3 to 6 feet. In this country it is rarely found so high, nor does it flower so freely as some of the other species and varieties. Its foliage, for which alone it is worth cultivating, is of a beautiful warm green tint, very delicate and abundant. The flowers are purplish-red, and produced in terminal clusters. It frequently suffers damage from our spring frosts, but always recovers in summer.

E. s. minima.—A very dwarf variety, and in point of foliage one of the most elegant of the Heath tribe.

E. Tetralix.—This beautiful species is found wild in all the northern countries of Europe, and very abundantly on the moors and heaths of Britain, growing to heights of from 1 to 2 feet. It is readily distinguished by its ciliated leaves, arranged in four whorls round the stems. The flowers are in terminal racemes, of a delicate pink colour, and generally in perfection from July to August.

E. T. rubra.—In this variety the flowers are of a much deeper red than those of the species.

E. T. alba.—A beautiful variety with white flowers, very showy and desirable.

E. vagans.—This species is found wild in the south of France, in some parts of Ireland, and very abundantly on the moorlands of Cornwall. It grows from 6 inches to 1 foot high, forming a neat compact little bush. The flowers are pale purplish-red, produced in great abundance along the branches. They are generally in per-

* "Handy Book of Ornamental Conifers, and of Rhododendrons and other American Flowering Shrubs." By Hugh Fraser. W. Blackwood & Sons, Edinburgh and London.

fection in August and September. It is an exceedingly showy plant invaluable for bedding and margins to clumps of the larger peat-soil shrubs, and forms a neat close edging for flower gardens.

E. v. alba.—Has pure white flowers, and is somewhat dwarfer than the species.

E. v. alba nana.—A very dwarf form of the preceding.

E. v. carnea.—The flowers of this variety are of a deep red or flesh colour.

E. v. rubra.—A very distinct variety with bright pink flowers.

E. vulgaris (*Calluna vulgaris*).—This is the common Heather or Ling of our moors, a plant so well known as to need no description. It is only noticed here as an introduction to an enumeration of its numerous varieties—most of which are so very beautiful that they should never be overlooked in forming a collection of hardy Heaths. They are all sports from the species, and have been found from time to time either associated with it in a wild state or in cultivation in gardens.

E. v. alba has white flowers, which it produces very abundantly.

E. v. alportii.—A strong-growing variety, producing large spikes of deep red flowers. It is a singularly beautiful plant.

E. v. aurea, or ignea.—A very distinct variety with golden variegated foliage.

E. v. argentea.—In this variety the leaves and branches are freely variegated with a silvery tint.

E. v. coccinea.—Flowers very dark red.

E. v. decumbens.—So named from its peculiarly spreading, prostrate habit of growth. Flower purplish-red.

E. v. dumosa.—This variety has a very dense, bushy habit of growth. Flowers light purplish-red.

E. v. flore pleno has a robust habit of growth, and double flowers of a pale purplish-red colour. It is a fine showy plant.

E. v. pygmaea.—A curious little plant, forming a neat, round, cushion-like bush, with short, rigid branches, and small flowers, usually produced very sparingly.

E. v. pumila.—Of a dwarf, compact habit, but otherwise like the species.

E. v. Hammondii.—A robust variety, bearing long spikes of snowy-white flowers; it is one of the most beautiful of the tribe, and ought to be very extensively cultivated.

E. v. rigida.—Branches, short and rigid; flowers pale purplish-red; a very distinct variety.

E. v. Searleii.—A neat compact plant with white flowers, which it produces in great abundance; one of the best of the hardy Heaths.

E. v. tomentosa.—This form occurs in great abundance in the southern counties of England, and differs from the species in its leaves and branches being covered with a minute down. The flowers are light purplish-red, and produced very abundantly in long spikes.

THE KITCHEN GARDEN.

SNOW'S WINTER BROCCOLI.

As Broccoli or Cauliflowers of some kind are expected to be ready at all seasons, it is especially important that the supply should not fail during the winter months, as then the loss of so important a vegetable is much more felt than when a greater variety is in season. I find the early winter supply is most effectually met by late planted successional crops of Walcheren and Veitch's Autumn Giant Cauliflowers. With timely attention to protecting the heads by tying up the leaves and packing dry Fern fronds amongst the rows, a regular and satisfactory supply of these may be kept up in ordinary seasons until near Christmas. On the first indications of severe frost we lift the remnant of these crops and plant them thickly in brick-pits thoroughly protected from frost. The first month or six weeks of the year is the season for proving which sorts are really Winter Broccoli, and few things with which I am acquainted are more vexatious than growing several highly reputed sorts of early and late Broccoli, and after looking in vain for the early sorts to come in, when there is a dearth of vegetables, to at last find both early and late kinds coming in together. After trying most of the early kinds, both new and old, I am confident that we cut more heads off Snow's Early Winter than all others put together. If one could depend upon getting this sort true no other would be needed, as it is of so thoroughly "self-protecting" a character that the heads, when fit for cutting, will withstand with impunity a frost that will destroy most other kinds. The object at which we aim is not the production of gigantic heads,

or a great quantity at any one time, but a constant succession of firm close Broccoli of medium size. We make small sowings during March, April, and May, and as soon as the plants are large enough, prick them out into nursery beds, and finally plant in open quarters or borders as the ground becomes cleared of early crops of Peas, Potatoes, &c. We have quite given up digging or forking the ground before planting this or any kind of Broccoli; for, if the soil is thoroughly manured and winter-cultivated for the preceding crop, the solidity acquired is beneficial rather than otherwise to the Broccoli. On soils in this condition the drought of summer has less influence, and the growth of the plants is more sturdy and robust than it otherwise would be, and, consequently, they are better able to withstand the inclemency of winter; their heads, too, are more solid and compact than those of plants grown on loose soil. If the weather is very dry at planting-time, we never wait for rain, but draw deep drills, at distances to suit the variety, and thoroughly soak them with water. We lift carefully and re-plant immediately, and after a good soaking of water, draw the dusty soil from between the rows, over the drill, and the plants grow away with scarcely any check. Frequent surface stirrings are beneficial in keeping down weeds, and in maintaining a loose surface.

JAMES GROOM.

Henham.

TRIAL OF CELERIES AT CHISWICK.*

FORTY-SEVEN reputed varieties were received for trial at Chiswick this year, and of these twenty-three were red and twenty-four white. These, by the detection of numerous synonyms, were reduced by the fruit and vegetable committee to twenty, viz., seven red varieties and thirteen white, which have been decided to be distinct. The seed was sown early in March in heat, and the plants pricked off and planted out early in June in single trenches, and treated after the ordinary manner. The plants were frequently examined by the committee whilst growing, and again when fully grown, and a portion of each sort was left to test their capabilities of standing the winter. The season of 1874 was a particularly favourable one for the growth of Celeries, so that the trial was a satisfactory one.

1.—Red Varieties.

1. **Manchester Red** (syns., Laing's Mammoth, Radford's Pink, Sulham Prize Pink, Hooley's Conqueror Prize, True Manchester, and Giant Red).—Plant of strong and vigorous growth, attaining an average height of 3 feet 4 inches; leaflets, broad green; heads, compact, average girth, 12 inches; the outer leaf-stalks are moderately broad, slightly shaded with red; heart, very solid; the stalks, broad, thick, and fleshy, blanching for about 12 inches; a very excellent sort, stands the winter well. This is the largest variety.

2. **Ivery's Nonsuch** (syns., Violet de Tours, Osborn's Select Red, London Market Red).—Plant of strong and vigorous growth and habit, average height, 3 feet; the leaflets are broad, deep green, the pinnæ more widely situate than in other varieties; heads, compact, average girth, 12 inches; the outer leaf-stalks flat, of a deep rosy colour; hearts very solid, blanching for about 13 inches; stalks very solid, broad, thick, and crisp, and of a fine nutty flavour. A very excellent sort, and one of the best to stand the winter.

3. **Kimberley's Red** (syns., Improved Solid Red, Stuart & Meix's Solid Red).—Plant of regular but somewhat spreading habit of growth; height, 2 feet 6 inches; leaflets, broad, deep green; heads, compact; average girth, 11 inches; the outer leaflets narrow, rounded, and slender, of a deep rosy-red colour; hearts very solid, blanching for about 12 inches; the stalks broad, thick, and crisp, of a fine nutty flavour.

4. **Carter's Incomparable Crimson** (syns., Carter's Incomparable Dwarf Crimson, Hood's Dwarf Red).—Plant of close compact growth; height, 2 feet 6 inches; leaflets, rather broad, pale green; heads, very compact; average girth, 11 inches; outer leaflets, narrow, deep rosy-pink; hearts, very solid, blanching for about 11 inches; the stalks, thick and fleshy, and of fine quality. This is the dwarfest red Celerie, and a good hardy variety to stand the winter.

5. **Webster's No. 1.** (syn., Webster's No. 4).—Plant of somewhat slender growth; height, 2 feet 10 inches; leaflets, broad with short petioles, giving it a bushy compact appearance; heads compact, average girth 10½ inches; outer leaf-stalks, slender and narrow; heart, solid, blanching for about 12 inches; the stalks, solid, thick, very crisp, and of good quality.

* The seeds for this trial were presented by Messrs. Carter & Co.; Barr & Sugden; Minier, Nash, & Nash; Harrison & Sons; Osborn & Sons; Stuart & Meix; Veitch & Sons; Yilmorin & Co; Mr. Samuel Simpson, Mr. R. Dean, and Mr. A. Parsons.

6. Leicester Red (syns., Major Clarke's Solid Red, Turnmess Red, Ramsay's Solid Red).—Plant of erect compact growth, presenting a very uniform appearance when growing; height, 3 feet; leaflets, rather small, deeply serrated, of a shining green colour, with a sort of silvery shade; heads, very round and compact; average girth, 12 inches; the outer leaf-stalks are rather narrow or rounded, of a clear rosy-pink colour; hearts, very solid, blanching well for about 12 inches, the inner stalks broad and thick, very crisp, and of a fine nutty flavour. One peculiarity of this Celery is, that of the core rising about 2 inches in the heart, as if it were to run to seed. This core portion is by many considered the best part. This variety, from its close compact growth blanches easily, and is the best Celery for autumn or early winter use, but it does not stand the winter so well.

7. Wright's Improved Grove Red.—Plant of the same appearance as Leicester Red, but somewhat dwarfier; the heads are also larger, being 18 inches in circumference; hearts, large, very solid, and good; this is an excellent sort.

3.—White Varieties.

8. Grove White.—Plant of strong and robust growth; height, 2 feet 9 inches. This is an exact counterpart of the Grove Red, but white, and possessed of the same excellent qualities. Does not stand the winter so well as other sorts.

9. Incomparable Dwarf White (syns., Plein Blanc Court Hatif, Sandringham, Doan's Compact White).—Plant of very dwarf and compact growth; height, about 24 inches; leaflets, small, pale green; heads, very compact, average girth about 10 inches; outer leaf-stalks, broad and deeply ribbed; hearts, solid, blanching about 10 inches, and of a pure white; the stalks, broad, thick, fleshy, crisp, and of fine quality. This is one of the best sorts, its close dwarf growth renders it easy to blanch with remarkably little earthing-up. It is good for early use, and also stands the winter well.

10. Plein Blanc.—Plant of dwarf compact habit; height, 24 inches. This is much of the same character as the preceding, but smaller and inferior. It is useful for an early supply.

11. A. Couper.—Plant, small; height, about 24 inches; leaflets, small; heads, small, outer leaf-stalks, very narrow. This is not of much use only for very early work, the small heart blanching very quickly. It soon runs to seed.

12. Turc Grand.—Plant of robust growth; height, 2 feet 6 inches; leaflets, large, broad deep green, outer leaf-stalks broad, much ribbed; heart, small. It may be useful for an early supply, but soon runs to seed.

13. Seymour's White (syns., Goodwin's White, Northumberland Champion White).—Plant of somewhat spreading habit of growth; height, 3 feet; heads, large, 12 inches in girth; outer leaf-stalks, broad, very deeply ribbed; hearts, solid, blanching to nearly 14 inches; the stalks, broad, thick, and fleshy. This is the largest-growing white Celery, and apt to become pithy if very strongly grown.

14. Prizetaker White (syn., Veitch's Silver White).—Plant of somewhat slender growth; height, 3 feet; leaflets, small, deep green, sharply serrated; heads, large, girth 11 inches; outer leaf-stalks, narrow; hearts, somewhat loose, blanching to about 12 inches; the stalks rather soft, but of fine flavour; rather tender.

15. Dixon's Mammoth White.—Plant of close compact robust growth; height, 2 feet 3 inches; leaflets, broad; heads, large; girth, 14 inches; outer leaf-stalks, very broad, about 2 inches; hearts, very large, blanching about 11 inches, somewhat soft, but excellent. It stands the winter well.

16. Great Eastern.—Plant of loose spreading habit, so much so that it is difficult to keep the heads together, and much addicted to throwing-up side shoots; height, 2 feet 9 inches; leaflets, small, pointed, very pale green; heads, small, girth 10 inches; hearts, loose and small. A very worthless sort, and decays early.

17. Haywood's White Queen (syn., Stuart & Mein's Giant White; Goodall's Flat-stalked; Webster's White).—Plant, of robust growth; leaves, spreading; height, 2 feet 9 inches; heads, large, 13 inches in girth; outer leaf-stalks, very broad (about 2 inches), much ribbed, and coarse; hearts, solid blanching in about 14 inches; the stalks very large, broad, thick, and fleshy; but without much flavour. An excellent sort to stand the winter.

18. Veitch's Solid White (syn., Dabesbury).—Plant, of close compact growth; height, 2 feet 6 inches; leaflets, broad, very deeply toothed or serrated, giving it a distinct appearance; heads, compact, girth 11 inches; outer leaf-stalks rather broad, deeply ribbed, pale green; hearts, very firm and solid, blanching from about 12 inches; the stalks broad, thick, crisp, and tender. A very excellent variety, and stands the winter well.

19. Boston Market.—Plant, dwarf, from 18 to 20 inches high; leaflets, small pointed and sharply serrated. This variety is not used to produce a single head, as the ordinary Celeries, but having the

peculiarity of forming a number of side shoots or small heads which are blanched. It is sited for early work, and it begins to run to seed almost as soon as planted out.

20. Frise, Curled or Garnishing.—Plant of loose growth; height, about 2 feet; leaves, very pale green, and deeply cut or curled almost like Parsley. It is very ornamental. The leaves may be used for garnishing, but it is of no other use. It is very tender, and runs early to seed.

21. Turnip-rooted (syns., Celeri navet; Rave; Rave d'Erfurt; Soup Celery).—This is quite a distinct vegetable, the plant forming a large bulb at the base of leaf-stalks like a Turnip. This bulb is used in soups, much in the same way as Turnips, and not the leaf-stalks as in other Celeries, and requires no blanching. It is not much cultivated in this country.

A. F. BARRON.

DIGGING.

For this purpose, the best tools, no matter what may be their first cost, are the cheapest in the long run. As regards spades and forks, one made of the best steel will last as long, or longer, than two of the common, clumsy, soft implements usually sold by country ironmongers; but even this difference, although important, is small in comparison with the increased quantity and quality of the work done by a man furnished with the improved tool. I have sometimes met with workmen who were opposed to any change being made in the way of implements; and in this matter there is an immense amount of latent conservatism in most districts; but a small amount of perseverance, accompanied by a practical demonstration of the superiority of the improved tools, is generally sufficient to convert the most stubborn stickler for old-fashioned modes of doing work. I do not know any single operation in gardening so illustrative of personal character as digging. I never yet knew an idle careless man make a good digger, nor a man who could dig well, and put his heart into his work, who did not prove a useful handy man at any other work to which he might be put, with a small amount of training. No young gardener, who wishes to rise, ought to despise the spade, as its proper use, either by himself or others, has more influence upon his future career than any other tool with which I am acquainted. Digging is even now, in many places often imperfectly done. Yet there is no work that is more important. In digging or trenching in autumn and winter, the ground can be scarcely thrown up too roughly. As large a surface as possible should be exposed to the action of the atmosphere; no time should be wasted in attempting to chop and cut it to pieces, as the weather will do that better than any workman can, however careful he may be. The great point is to work the soil up deeply and roughly, and then in frosty weather, if possible, to take a pick and pick it over so as to loosen up the frozen crust and let in the air still deeper. On no account, however, should snow be turned into the ground, nor yet in trenching should frozen soil be deeply buried, as, when thus turned down, it is a long time before it thaws, and for a long time after it remains wet and sodden. As spring comes round we can no longer count upon frost as an ameliorator of the soil; therefore, in all digging which it may be necessary then to do the soil must be thoroughly broken up with the spade, especially where land is constantly under crops. In some soils, too, dug deeply after February there is often a difficulty in securing the necessary firmness. If too much air is let into such as are naturally porous, plants may suffer from drought, even though the season may not be dry. In short, though digging may seem a simple operation, very much depends upon its being done at a right time as well as in a right manner, and the right time depends in a great measure upon the character of the soil and sub-soil, and upon the nature of the succeeding crop.

E. HOBDAY.

Russian Mode of Forcing Asparagus.—This, according to a writer in the "Almanack du Jardinier," is very successfully done as follows:—Towards the close of September well-established Asparagus beds are covered with well-rotted manure or leaf mould 14 inches deep, the mould extending 1½ feet beyond the edge of the bed. When the moment for beginning to force arrives—October, November, December, or later still—a layer of fresh manure, ready to ferment, 28 or 30 inches thick, is spread over the entire surface of the first stratum, and the whole covered with matting. Three weeks afterwards the growers cut fine Asparagus from 6 to 8 inches long. To get at the Asparagus, the beds are uncovered over lengths sufficient to supply the quantity required. When the cutting is taken, the plants are covered again exactly as in the first instance; namely, with 14 inches of spent manure or leaf mould, and an upper layer of fermenting material some 30 inches thick. Asparagus grown in this way is said to be excellent and eatable throughout its whole length. Such quantities are gathered that it is exported from Moscow, where it is grown as above described, to all parts of the Russian Empire.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 19TH.

At this meeting, Messrs. Veitch & Sons staged an attractive collection of new and rare Orchids, Palms, Bromeliads, and Cyclamens. Mr. Green, of Reigate, furnished a choice selection of new or interesting succulents; and an interesting collection of late Pears came from the Society's garden at Chiswick.

First-class Certificates.—These were awarded to the following: **Dendrobium teretifolium** (Denning).—A very singular Australian species, popularly known as the Cobweb Dendrobe. It has thick aerial roots, woody, zigzag pseudo-bulbs, and from five to seven-flowered spikes of whitish blossoms, the linear segments of which remind one of those of *Oncidium phymatocilium*. The lip is curiously curled, or revolute, and terminated at the apex by a slender tail. The leaves are from 6 to 9 inches in length, and of a glaucous green colour, thong-like, or terete, and hence the specific name. It had been flowered in a cool temperature, and bore forty spikes, on which there were about 200 flowers. As shown by Mr. Denning, this plant is certainly by no means unattractive. It was figured many years ago in the "Botanical Magazine," v. 79, t. 4, 711, having then flowered in Messrs. Loddige's collection.

Mesembryanthemum truncatellum (Green).—This is a curious and interesting species from the Cape of Good Hope, and one which rarely bears more than four thick rounded leaves. The specimen shown was not in flower, but in the "Botanical Magazine" for 1874, t. 6, 077, it is represented as bearing bright yellow-rayed flowers nearly 2 inches across.

Chicory or Witloof (Carter).—This is the Witloof or White Leaf which is grown in French and Belgian gardens as a salad vegetable; its flavour is delicately bitter and superior to that of either Endive or Dandelion. It is in reality a large, close-growing variety of common Chicory. A figure and description of it will be found in THE GARDEN, Vol. VII., p. 331.

Orchids.—Of these, Messrs. Veitch & Sons had a fine collection, in which we noticed several flowering plants of *Odontoglossum Roezlii*, including white, pink-spotted, and purple-blotched varieties; *O. Pescatorei*, with a twelve-flowered spike; pink and white forms of *O. Rossii majus*, both forms bearing four-flowered spikes of large blossoms of excellent substance. In all, four forms of this plant were shown. The free-blooming *Oncidium cheirophorum* was represented by two healthy and floriferous little specimens; and a fine vigorous plant of *Angraecum sesquipedale* bore three spikes, on each of which there were 12 flowers. This is the largest-flowered of all Orchids, and has a spur fully 13 inches in length. A fine plant of *Odontoglossum Hallii* bore a twelve or fourteen-flowered spike of yellow and white, chocolate-spotted blossoms. *Masdevallia tovarensis* was represented by the specimen which we alluded to in our "Notes" the other day (see p. 26) as being furnished with seventy flowers and buds. Among Lady's-slippers we remarked *Cypripedium argus*, which, to the foliage of *C. barbatum* adds flowers on very long scapes; also a plant of the brown varnished *C. villosum*, bearing seven fine flowers; *C. Schlimmii album*, having four spikes, the flowers on which had less rose in them than in the normal form; two hybrid varieties were likewise staged by Messrs. Veitch, namely, *C. Crossianum*, a hybrid raised by Mr. Cross, gardener at Melchet Court, between *C. insigne* and *C. venustum*. Its flowers are yellowish-brown; the oval, dorsal sepal being green dotted with brown, and tipped with white. The other, *C. tessellatum*, is a hybrid, raised by Messrs. Veitch & Sons, between *C. concolor* and *C. barbatum*; it has purplish speckled flowers, about the size of those of *C. concolor*, with a curious flattened lip, and it bears two flowers on a scape; the leaves are like those of *C. concolor*, but broader and darker as regards the markings. Plants of *Lycaste Skinneri* and *Cattleya Trianae* completed the group, to which it was recommended a silver medal should be given. Mr. Hill, gardener to Sir W. Marriott, Bart., Down House, Blandford, sent a very fine plant of the old *Cattleya bulbosa*, bearing in all fifteen bright lilac purple-tipped flowers. Mr. Burnley Hume, Hill House, Winterton, contributed a fresh healthy specimen of the new *Masdevallia Davisii*, on which there were ten rich yellow flowers. This is a finer species than we had at first imagined, it would prove one which well deserves culture, being very floriferous and showy. Mr. Green had a group of *Masdevallias*, including a good plant of *M. polytricha* and two forms of *M. melanopus*.

Miscellaneous Subjects.—Messrs. Veitch staged plants of *Nepenthes philippensis*, a graceful-looking crisped species in the way of *N. pectinata*, but a stronger grower. A collection of hybrid *Amnylium* of the *A. pardina* and *A. Leopoldii* sections was shown; also specimens of the old blue-flowered *Eranthem pulchellum*; a pan of plants of the brilliant scarlet *Aphelandra aurantiaca* Roezlii; and *Tillandsia Lindenii*, a fine specimen, with a strong spike of bright blue Iris-like flowers, and three other spikes pushing up from the elegant rosette of slender arching leaves. Associated with these, we also noticed *T. Zahnii* bearing a spike of bright yellow flowers, each tuft being subtended by crimson-stained bracts. This plant has somewhat the habit of *Lindleyi*, but is of a much nobler habit, and, apart from its attractive inflorescence, it deserves culture as a fine-foliaged plant. Mr. Chambers, of Mortlake Nursery, Isleworth, contributed six seedling varieties of *Hoya carnosae*, including *H. carnosae picta* and *H. C. variegata*. Mr. Green, of the Botanic Nursery, Holmsdale Road, Reigate, sent a choice and interesting group of succulents, several of which were new and unnamed; among these we remarked a new dark-leaved *Aloe* from Magdala, *Decalobona elegans*

("Botanical Magazine," t. 6, 115), *Mesembryanthemum truncatellum*, and one or two other highly interesting kinds; also *LOBELIA subulata*, a kind with finely-cut leaves, and furnished with panicles of white flowers. In habit and general appearance this closely resembles some of the Saxifragas. Messrs. Stewart & Mein, Kelso, sent a fine plant of the old *Rhipsalis pachyptera*, 3 feet in height. This plant has large rounded phylloids similar to those of *Opuntia*, but thinner in texture, their margins being fringed with golden-yellow buds and white myrtle-like flowers.

Fruits.—In the competition, which took place on this occasion, for Mr. William Paul's special prize, offered for the best bunch of Waltham Cross Grapes, Mr. J. Douglas, of Loxford, was first with a good cluster, the berries in which were very fine, well coloured, and remarkably fresh for the season. Mr. J. W. Chard, Clarendon Park, Salisbury, was second with a much smaller bunch. Mr. Chambers contributed a box of Blenheim Orange Apples, in excellent condition; and a collection of dessert Pears, of excellent quality, came from the Society's garden at Chiswick. Amongst these we noticed samples of Winter Nélis, Passe Colmar, Glou Morceau, Beurré Sterckmans, Belle après Noël, and Beurré d'Espérance. M. Cox sent specimens of the Redleaf Russet Apple, a kind which resembles the Royal Russet in form, and one which is rich and good in flavour. Mr. W. Taylor, gardener to the Marquis of Bath, at Longleat, showed a fresh and handsome dish of the Orangefield Tomato.

Vegetables.—Messrs. Carter & Co. sent a sample of Porter's Excelsior Potato, and also specimens of Witloof, which, blanched, forms a most excellent salad vegetable. Messrs. Stuart & Mein furnished specimens of their strain of Chilian Beet, including pink-white, crimson-orange, and yellow-stemmed varieties; also their Proliferous Green Curled Borecole. Mr. Walker, of Thame, showed three fine bulbs of selected white Spanish Onion; also his Long Keeping, which varied from the white Spanish one in having a brown skin.

Royal Horticultural Society's Schedule for 1876.—This differs materially from its predecessors as regards the number of exhibitions, which are limited to four, viz. the spring flower show in March, the great plant and fruit show for two days in June, the show of cut Roses, Fuchsias, succulents &c., in July, and the customary fruit and *Chrysanthemum* show in November. The lists of prizes at these shows differ but little from those issued in previous years, but there are one or two noteworthy alterations. Thus, at the March show, the old class for hardy plants in pots is eliminated, and in place thereof good prizes are offered for fifty hardy spring flowers and shrubs in pots unforced. Another class is introduced for thirty spring flowers and shrubs forced. In the schedule for the June show the prizes for hardy plants are withdrawn, a matter to be regretted, as these have invariably proved most attractive. It is gratifying, however, to find that the class for twelve *Dracaenas* originally cut out has been reinstated. The list for July presents no new features, but it is satisfactory to observe that the class for bedding succulents has been retained. The most gratifying feature of the November fruit show is the fact that fruit grown abroad and in the Channel Islands, has been assigned a class to itself. A new class is introduced for twelve berry-bearing plants in pots, an interesting display of which may be expected.—D.

NOTES AND QUESTIONS—VARIOUS.

Chrysanthemum virginale.—This is the name of the white *Anemone*-flowered *Chrysanthemum* figured in THE GARDEN (p. 33). I have grown it for many years; it is the latest white variety, and was sent out in 1870 by Mr. J. SALTER. It is a valuable kind on account of its lateness, as it is always in bloom and quite fresh at Christmas.—T. DAVIS, Park Nursery, Plumstead Common.

Pitcher Plant "Sports."—We have an old plant of *Nepenthes distillatoria* here which has thrown out a young shoot near its base, that bears pitchers like those of *N. Rafflesiana*, whilst on the other parts of the plant the pitchers are those of *N. distillatoria*. I have hitherto considered the two kinds distinct, but the circumstance just recorded would lead to the belief that one is merely a sport from the other. *N. distillatoria* is said to have been introduced from China, and *N. Rafflesiana* from Singapore.—W. H.

London Pride as an Edging to Winter Beds.—This is one of the best plants with which to edge winter beds that I know of. It takes the place of *Berberis* in summer bedding, and is thoroughly hardy and easy to increase. It is well adapted for rough rock-work or for naturalisation in shrubberies and woods. When well established, clumps of it form quite a cloud of delicately-tinted blossoms in May. Its neat rosettes bloom freely in spring, and furnish them one of our prettiest flowers.—J. GROOM.

Cattell's Eclipse Potato.—This received a first-class certificate at the Chiswick Potato trial two years ago. It is a good late kind, and deserves extensive cultivation for spring consumption. The tubers are long and flat, and somewhat fluke-like. The skin is rough and netted; the flesh white, soft and mealy, and well flavoured. It is one of the best for ripening, and for that reason is useful to cultivate for the latest consumption.—D.

Corners of Box Edging.—No greater eyesore can exist in a kitchen garden edged with Box than trodden-down corners. For this, the best remedy is to drive good strong stakes, at least 2 feet long, into the ground in a sloping direction, until they just cover the edging. These are not easily removed, and it is surprising how soon passers-by learn to avoid them; the corners thus protected grow as freely as any other part of the edging.—J. GROOM, Zenham.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

WINTER GARDENS IN GREENHOUSES.

AMONGST the multitude of glass structures annually erected in this country, a great many are wholly or inadequately provided with heating apparatus. These occur chiefly in villa gardens, and, as a rule, present a somewhat forlorn appearance in winter. This need not, however, be the case, as, by a judicious selection of shrubs and plants, they might easily be made to assume a cheerful aspect; many shrubs, although commonly grown out-of-doors, are all the better for the protection which a glass-roof affords. The golden variegated *Euonymus*, *Laurustinus*, Sweet Bay, Myrtle, *Skimmia japonica*, berry-bearing *Aucubas*, and some Conifers, look well and succeed admirably even in pots, in which they may be kept for several years in good condition. If plunged up to their rims in a cool situation during summer they require no other attention beyond copious waterings in dry weather. Some pretty hanging baskets may be made with variegated *Ivies*, some of the evergreen *Sedums*, and the variegated *Periwinkle*, which, under such circumstances, has a light and elegant appearance. I have a large specimen of it at the present time, which, owing to its distinct and constant variegation, always looks fresh and cheerful; baskets, filled with such plants, should in the summer time be suspended in some cool airy place, and a little manure-water should occasionally be given them. Among flowering shrubs we have *Deutzias*, *Spiræas*, *Rhododendrons*, *Kalmias*, *Laurustinus*, *Daphne Cneorum*, Chinese *Azaleas*, and many others. These, in an improved climate, under glass, will flower earlier and in greater perfection than in the open air. They need not be annually shifted and potted; on the contrary, I have grown *Deutzias* for several years in succession in the same pots, and kept them in good condition by the aid of weak stimulants applied during the growing season. *Polyanthuses*, of which many fine varieties can now be had, are all the better for a little shelter, as is also *Primula japonica*. A few potsful of *Neapolitan Violets*, *Lilies of the Valley*, *Forget-me-nots*, *Heartsease*, and similar plants will suffice to keep a little glass-house gay and interesting; and if in early spring, after all danger from frost is over, a few *Cinerarias*, Chinese *Primulas*, *Cytisus*, and other showy-flowering plants which at that season of the year are within the reach of everybody are indulged in, a veritable little Eden may be created in what was formerly, comparatively speaking, a desert. A covering of mats laid on nightly will keep all safe from spring frosts. Many Ferns, too, would succeed admirably in such houses. Among *Scolopendriums* alone, there are numerous singular and beautiful varieties, and *Cyrtomium falcatum*, *Lastrea opaca*, and *Onychium japonicum* may be instanced as peculiarly adapted for such purposes. The size, form, and general arrangement of the plants in such places will, of course, depend upon the taste of the grower, and the interior shape and fittings of the house. Supposing it to be a lean-to, which is generally the case in villa gardens, there will probably be a level front stage, and either another occupying the back part of the house, or, as is oftentimes the case, open space from the path to the wall. The front shelf may be filled with the smaller kinds of bushy plants, including Ferns, arranging them with due regard to contrast, and bringing them down gradually from the front sashes towards the path, the whole to be edged by a row or two of *Primroses*, *Violets*, and similar plants of dwarf habit; if there be no back stage, which for our purpose would be preferable, the wall should be wired or latticed and covered with some evergreen Tea and *Noisette* *Roses* with good high stems in pots. These will furnish a profusion of flowers some time before they can be obtained outside. In summer they can be untied and moved out of doors to make new growth. I have seen some very fine *Roses* produced in this way. A few tall *Rhododendrons*, Conifers, *Bays*, and similar plants should be placed near the *Roses* in

such a way as to cover their bare stems; in front of these other plants should be placed according to their heights, so that the whole may form an interesting bank of verdure. Here and there a strong post should be driven into the soil to serve as a support for a piece of board or bracket on which a flowering plant may be placed, taking care that the stand is sufficiently low to admit of the pot being effectually concealed by the surrounding foliage. In this way excellent effects may be produced, examples of which are not uncommon on the Continent. There banks of evergreens often exist, among which flowering plants are interspersed in the manner just described. A broad border of *Selaginella* forms the edging, amongst which are plunged *Daffodils*, *Squills*, *Primroses*, *Hyacinths*, dwarf Ferns, and similar plants, the whole presenting an unstudied and natural appearance. One advantage belonging to this style of arrangement is the greater variety which it affords, and the ability to make more of one's blooming plants than otherwise could be done. In these remarks, I have only named such plants as are easily cultivated, and which may be readily procured. To these I would recommend attention to be paid at first; but the collection may be gradually extended, so as to include some of the rarer kinds. Many who possess a small greenhouse would be glad to devote a little time to its decoration; but where the plants usually grown in pots in such houses are kept, they are debarred from doing this, owing to the constant attention which they require. They would like to see their glass-house furnished; but they are only able to deal with soft-wooded plants, and the expense of firing and labour, under such circumstances, is more than they can afford. To cultivators, placed under such conditions, I would therefore say, Give the system to which I allude a trial. JOHN CORNHILL.

Byfleet.

PRUNING FOR A CROP.

THE object of pruning is undoubtedly to increase the fertility of fruit trees; yet, in many instances, that object is entirely defeated by the very means that are supposed to be best calculated to produce good results. One of the chief causes that tend to failure is the too strict adherence to orthodox rules, without studying their effect on individual varieties, viz., making the form of tree and specimen of training of primary importance, and rendering the fruit-producing qualities subservient to the form of the tree. It is a very pretty addition to a garden to have rows of trees the very reflex of each other as regards symmetry, &c., whether pyramidal, horizontal, or any of the numerous devices into which a tree can be trained. But while some kinds will conform to this, and still maintain their fertility, others resent such treatment, and produce little else but leaves and useless wood. If we take the *Vine* as an instance of forced fruits, and one which, under any circumstances, must be badly used to make it unfruitful, we shall not find the same mode of pruning the best for all kinds; for, although *Hamburgs*, *Sweetwaters*, and many varieties, will show fruit at every bud if the wood be well ripened, thus enabling them to be pruned as close as walking sticks, yet other varieties—of which the *Barbarossa* is a type—will produce scarcely any bunches, if close pruned, for several years. But if young rods be annually led up to replace worn-out ones, the produce will equal, if not excel, the most prolific of other kinds. For open-air culture of *Vines* on walls, I am decidedly in favour of a modified form of the long-rod system of training; and new vigour may be infused into old *Vines* by gradually replacing the old rods with young ones. As regards the cultivation of stone fruits on walls, I prefer the fan system of training to all others, for many reasons, not the least of which is that it admits of a constant succession of young bearing wood being introduced without necessitating the removal of any of the main branches. For, although *Apricots*, *Cherries*, and *Plums* will bear freely on spurs, the fruit is not so fine as on the young wood, neither does it receive the full benefit of the wall, either when in blossom or ripening. *Peaches* and *Morello Cherries* are usually trained so as to depend entirely on the preceding year's wood; and I find the same mode of training may be adopted with advantage for many other kinds. Fruit borne on long spurs away from the wall is in but little better position to that borne on

standards. The horizontal form is generally adopted for Pears, either as a wall, tree, or espalier, but requires great care in pruning, or the centre of the tree will produce little save breast-wood, at least with the majority of sorts. Young bearing wood cannot be trained between the principal branches, so as to receive the full benefit of light and air, and the outline of the tree is entirely destroyed, if straight lines be in the least departed from. Pyramidal and bush trees admit of great latitude as regards the retaining of young fruitful shoots, and are therefore preferable. Moderately strong straight growths are essential in forming the main branches in all forms of training; but anyone conversant with fruit culture must be aware that it is on the small well-matured spray-like growths that fruit-buds are most abundant: and when the form of training does not admit of these being retained, I consider that it is opposed to the real object for which the fruit tree should be grown.

JAMES GROOM.

Henham.

CHRYSANTHEMUMS FOR FURNISHING.

THOUGH the Chrysanthemum is not a flower which one cares to use much for bouquets, yet it is one of the most generally useful that we possess for other decorative purposes, wherever display is an object—coming in as it does when most other flowers are scarce. There are many Chrysanthemums now, the flowers of which are really beautiful, and indeed but little inferior to those of the Camellia. Let me state, therefore, for the benefit of the uninitiated in its culture, that it is easily propagated by division of the roots, and by means of layers and cuttings. By division is the best plan, where a stock of good bushy plants and plenty of tolerably good flowers are wanted without much trouble. I have seen as good a display of flowers upon plants of this kind as anyone could desire, either for conservatory decoration or for cutting. When Chrysanthemums have to be propagated in this way, save the old stools, keeping them, after being cut down, in as cold quarters as possible till spring; for it does not do to force growth early in the season. About the beginning of April shake out the stools, and divide them into two, three, or four pieces, according to their size and the size of the specimens desired, and pot in well-drained 9, 10, or 12 in. pots, as may be needful, using good substantial loam mixed with a little cow manure, if procurable, and leaf-mould or peat; but let it be loose and rich. After potting, set the plants in a cool frame, if available, or, if not, all closely together in some warm sheltered corner out-doors, and protect them from frost, when required, by some temporary covering. When they begin to grow freely, plunge the pots to the rim in a bed of ashes, in the ground in some sheltered situation, and be sure to water them freely, using very weak limpid manure frequently. By-and-by the roots will push through the bottom of the pot into the soil, to prevent which lift the pots clean out of the ground once every fortnight. If the shoots seem to be too thick they may be thinned out, and to preserve the foliage intact, do not spill any manure-water on the plants in watering; in fact, do not water over the foliage at any time, but use the spout of the watering pot without a rose, and water abundantly, never allowing the plants to flag while they are growing, or stunted growth and a premature development of inferior flowers will be the result. Plants propagated by division need not have their shoots topped, but may be allowed to grow on uninterruptedly; and, if all has gone on fairly, they should be good bushy specimens, well furnished with flower-buds, by October. Before they get top-heavy, or are in danger of being blown about by wind, they should be supported by putting a small stake to each shoot. The plants should be housed before the buds suffer from frost, though a few degrees will not injure them. If flowers be not wanted till late in the season, they are better left out-of-doors as long as possible. When they are taken in, let it be to one of the coolest houses, from which they can be introduced to the greenhouse or conservatory, as desired; but when under glass they must have light and air in abundance, and not be allowed to suffer from want of water at the root, otherwise mildew (the worst enemy of the Chrysanthemum) will appear, and will soon destroy both flowers and foliage. When this disease is noticed, sulphur dust-

ings must be at once applied, and a little heat to dry the air will also help to check its progress. Chrysanthemums do not bear forcing well, and should not need pushing if the plants be well grown and matured. A temperature of from 45° to 50° suits them well, and will bring the flowers out in proper form. Another way of growing plants by division is to plant them in the open border about 3 feet asunder, and take them up with balls and put them into pots in October. By far the most vigorous plants are got up in this way, but they suffer considerably in the lifting. When grown for the market they are sometimes planted out in this way, and, instead of moving the plants, a temporary glass structure is placed over them during the winter. Exhibitors maintain that Chrysanthemums raised from cuttings produce the finest flowers; but their superiority is probably due to the extra attention which the plants receive in other respects when grown as specimens. Cuttings of them should be put in in February or March, and the young shoots that spring from the old stools should be used for the purpose, cutting them off at a joint, and about 2 in. long. They will be found to strike readily in a temperature of from 60° to 70°, or in an ordinary cutting frame, if inserted in shallow boxes of sand and leaf-mould, or in pots like other cuttings; but they should be removed from the warm frame, to an ordinary greenhouse temperature as soon as struck, as they dislike fire-heat as much as Calceolarias. When hardened off a little they should be potted, one or two together, in 4 in. pots, have their tops pinched, and be placed in the greenhouse again, or a cool pit, placing the pots closely together to prevent too much evaporation and consequent drought about the roots. In April they may be finally shifted, using pots in size proportionate to the specimens desired. At this stage the shoots should be pegged down to the soil to form the base of the future plant. When they have grown a little they will need another pegging before the pot is covered, and another pinching of the tops, performed so as to secure a well-balanced specimen; but all pinching should be discontinued before the middle of June, and the shoots allowed to extend as fast as they will. After this watering and similar matters must be attended to as before directed. S.

BOUGAINVILLEA SPECTABILIS IN INDIA.

WITH reference to the note (see p. 83) on the flowering of a Bougainvillea eighteen months old, I may mention that a plant of that age would, in the open air, be much larger at Bangalore, and at the present time would be showing a few of its lovely mauve or Peach-coloured bracts that are so admirably set off by little flowers of the proper complementary colour. The following brief description of its growth and habit at Bangalore and Madras—one being a dry and the other a moist climate—may lead cultivators of this beautiful plant to come to some definite conclusion as to the best mode of treatment for it here. At Bangalore rain seldom falls from the middle of December to the middle of April, and throughout February, when the Bougainvillea is at its brightest, the days are warm, and the north-east wind often blows with considerable force, but the nights are cool and still. The means for that month of the corrected readings of the thermometer for the three years 1871, 1872, and 1873, recorded at the Civil Hospital Observatory—which, though protected from the sun, is free to every breeze, and is 3,000 feet above the level of the sea—are as follows:—maximum, 84°; minimum, 61°; and the mean temperature, similarly calculated, 72°·5, which corresponds almost exactly with the mean annual; the mean humidity for February (100 being maximum) is 59, while for March it is only 49; the corresponding means for the whole year were 82°·33, 64·00, and 72°·47; the maximum during any one day of that period being 95, and the minimum 54. This grand climber flowers most luxuriantly at Bangalore and other places in the Mysore country at an elevation above mean sea-level of from 2,000 to 3,000 feet. It grows without the least care or attention in the ordinary red soil, and, notwithstanding a hot sun, high dry wind, and driving dust, it is now exhibiting, at every turn, magnificent masses of its rich inflorescence, which is so abundant as to throw the true foliage completely into the shade. The effect of this on a specimen some 35 ft. high, bathing in the sunlight, is almost indescribable. At

Madras, where the heat is greater, and the atmosphere is charged with much more moisture, the *Bougainvillea* does not flower. It makes sturdy enough growth in the ordinary blackish soil; but under such conditions, it persistently refuses to flower, notwithstanding all the efforts made to induce it to do so, by pruning and manuring it, or by letting it have its own way. Without seeing the plant in question and its surroundings, it is difficult to say what should be done to it in its present stage. The temperature of the house is not given, nor the hygrometric state of the atmosphere. If it be at all like that of Madras, the reason of its refusal to flower seems capable of explanation; and it would be reasonable to endeavour to imitate, to some extent, the warm dry climate of Bangalore. The growth may have been forced too much in ungenial soil; and it might be necessary to pinch it in a little, though this should be avoided if possible, and to give the roots more room than a 14-in. pot will admit of. Probably if it were merely transplanted into a prepared bed of rich red loam, opened with good old manure and a little coarse sand, and watered gently so as to keep the soil moist, it would respond well to the treatment; and if by some arrangements of the pipes the bed could at the same time be slightly warmed, and the young plants be given as much air and sun as this uncertain climate will permit, the growth would possibly be so decided as to induce it to put forth some inflorescence during the hot weather of the coming July. By analogous treatment, taking the difference of climate into consideration, a very well-rooted layer, about 3 ft. in height, succeeded wonderfully. It was planted against a gable end in the Lál Bágh in July, 1872. By February, 1873, it had made a good spreading growth, and then put forth a few bracts at the ends of the shoots; the same treatment was continued, and by the succeeding February it not only covered the gable end, and began to overlap the roof of the summer house, which is 20 ft. from the ground, but came out in abundant inflorescence. It was transplanted into a bed such as is described above, carefully watered, and trained against the wall, which was exposed to the full blaze of the sun till 3 p.m. Pinching and pruning were not allowed, with this exception, that any foreright shoot that could not be laid properly in the desired direction was cut out. Under such treatment, the most satisfactory results were obtained, for the plant, while it made the most vigorous and rapid growth, was in the highest state of health, and the inflorescence appeared to me to be of a deeper and more beautiful colour than if it had been left to itself. J. P.

Genera Cinnabrina for Winter-table Decoration.—This will endure the changeable temperature of a dining-room or hall, better than any fine-foliated plant with which I am acquainted. I prefer the following treatment to that of growing a number of plants in one pot, a plan which has been recommended. As soon as the stems are decayed, shake the plants out of their pots, place the bulbs in a pan filled with peat and silver sand; and when the young shoots are 2 in. high, re-pot singly in 48-sized pots, using a mixture of loam, peat, silver sand, and well-decomposed sheep-droppings. While they are in active growth, I water freely with weak liquid manure, made from sheep-droppings, and continue to do so until the flowers appear; after which I use nothing but soft water. Under this treatment, from three bulbs broken up into small pieces, I had four dozen fine plants, well furnished with foliage. Young plants with a single stem, flowered in small pots, I find to be much more effective than when they are allowed to branch.—J. M' A., *Clyde House, Dublin.*

Begonia Frœbelii.—This new species of a genus, now becoming yearly more popular, is not only a really splendid acquisition, but is also a very distinct plant. Like that of B. Veitchii, its foliage is all radical, and is clothed with a plush-like tomentum, especially on its under surface. The flower scapes are very stout, much branched, and of reddish-purple colour, becoming more vivid near the summit, where the branches each terminate in from three to four deep vermilion-coloured flowers, perianth, germen, and peduncle being of nearly the same tint, though the seed vessel assumes a greenish hue after the flower has fallen. The stamens of the sterile flowers are remarkable for having linear anthers, and the stigmas are of an unusual form. It is a native of Ecuador, and, being found at a considerable elevation, there is good reason for believing that it will prove quite hardy in England.—W. THOMPSON, *Ipsoviech.*

NOTES OF THE WEEK.

— WE have recently tasted some of the sweet Capsicums "Pimientos dulces," familiar to few in this country, but much liked in various parts of Spain. They have a very agreeable and distinct flavour, with barely a trace of the pungency of the Capsicum. The sample we tasted was a preserved one; this variety would seem to be well worth a place in English gardens.

— THE recently-issued schedule of prizes offered by the Royal Horticultural Society shows that the number of exhibitions for this year has been cut down to four, among which no mention is made of a provincial show. The amount of prize money to be awarded by the Society is about £1,115, and special prizes are offered by Mr. Bull, Messrs. Veitch & Sons, Carter & Co., Sutton & Sons, and by Mr. Monro, the total amount being about £358.

— A GERMAN correspondent of ours has purchased a little valley in the Central Alps with a view to cultivate Alpine plants on an extensive scale for purposes of observation. This reminds us of the lovely Alpine gardens that might be made in many stony wastes and rocky knolls in various hilly parts of England. Our Augsburg friend proposes to give us in due time an account of his mountain garden.

— MESSRS. WERKS, of Chelsea, have, for their handiwork shown at the Cologne Exhibition, received one of those very ugly and inartistic "diplomas," which German lithographers alone know how to produce, and, in addition, a massive gold medal and £50, as a reward for their skill and enterprise.

— IN a quiet little garden, beneath the shadow of Peterborough Cathedral, the winter Heliotrope (*Tussilago fragrans*) is now blooming freely, and is forming large patches close to a sunny wall. In the same little garden we saw, last spring, a large breadth of the lovely blue Apennine Anemone (*A. apennina*), which then looked as though it had been long established in that little nook.

— THE declared value of Potatoes imported into the United Kingdom last year was over one million and seventy-one thousand pounds. This may serve to show how much room we have for improvement in this and many other directions. Even the common Horseradish is now imported in quantities from the Continent. Why we should pay millions annually for products that might easily be grown in our own country is a question that will some day have to be answered.

— THE opening of the new aquarium at Westminster, which took place on Saturday last, has some interest for horticulturists from the predominance given in it to floral decoration and from its connection with proposed great flower shows. Nothing could surpass the good taste and abundance of the floral display made by Mr. Wills, who causes many to wonder where he finds his seemingly inexhaustible supplies of forced Lilies of the Valley and other choice flowers of the season. The Lilies dotted all over the beds and borders as if in their native woods formed the largest and finest display of forced blossoms we have seen.

— LAST week the additional improvements on Clapham Common were completed, and the Metropolitan Board of Works, who rescued this suburban land from speculative builders, by purchasing the manorial rights at a cost of £17,000, will not enclose any portion of the common, but preserve it as an open park for the public. The gravel and other pits have been filled in. The Mound, and the Long, Windmill, and Island ponds will be kept as ornamental water. The handsome Chestnut trees will not be disturbed, nor the "Nine Elms." A long avenue of trees has been planted by the road-sides. The digging of turf and gravel and cutting of furze will be prohibited. The common rights of the ratepayers to the pasturage of cattle are not interfered with, and sports and pastimes are permitted; but many of the objectionable innovations which existed will be suppressed.

— M. LEMOINE announces two double varieties of tuberous-rooted Begonias, for distribution during the present year, namely, B. Gloire de Nancy, the habit of growth and foliage of which resemble those of B. boliviensis, the central or male flower of each fascicle of three being fully 2 in. in diameter, and as double as a Camellia-flowered Balsam, the colour being a rich vermilion-scarlet. The other, B. Lemoine, is of more dwarf habit something approaching that of B. Sedeni, the flowers being borne on much longer peduncles. The flowers measure fully 2½ in. across, are very double, and of a vivid orange-scarlet colour, flushed with vermilion. Both are said to be very attractive plants for indoor decorative purposes, being as easily propagated and grown as the single varieties. It is interesting to note that in all the double-flowered Begonias the duplication is confined to the central or male flower of each fascicle, the stamens of which are transformed into petals, while the female flowers retain their normal form and arrangement of parts.

ARISTOLOCHIAS.

THESE free-growing twiners, remarkable for the grotesque appearance of their flowers, come mostly from the hot, damp regions of the Western Hemisphere, and, therefore, are particularly suited for clothing pillars or rafters in warm stoves. They may also be easily grown in the shape of trained specimens if required, a mode of treatment by which their singular flowers can be more easily examined than they otherwise could be. They may be readily struck from cuttings made from half-ripened shoots, taken off with a heel. This is necessary, as, if strong, succulent shoots be used, they are liable to damp off, unless the base of the cutting consists of a portion of the more solid wood, formed at its junction with the mature shoot from which it has sprung with sufficient heat. They may be struck at any time of the year, but they are generally in the most suitable condition about the end of March; put them singly in small pots, with a little drainage in the bottom, on which is placed a mixture of half-sifted peat and sand, with a little clean sand on the surface; place them under a propagating glass, and keep the soil moist, as succulent cuttings, such as those of Aristolochias, require a good deal of moisture, otherwise they are likely to flag, which has the effect of seriously retarding the formation of roots; let them be in a temperature of 70°, and shade closely from the sun. They will root in a few weeks, when they should be at once transferred to 6-in. pots; being mostly strong growers, they will succeed in almost any description of good soil, sufficiently porous to allow the large quantity of water they need to pass freely through it, yet good loam is preferable to peat, as in it they do not run so much to leaf, and form flowers more freely. For this first potting, sift the loam and add one-sixth of leaf-mould and a moderate quantity of sand. The plants should now be kept in a temperature of 75° during the night, with 10° higher during the daytime, and a little air on when the weather is sunny; a slight shade will be required when it is bright, using the syringe freely in the afternoons. By mid-summer the roots will have filled the pots, they should then be moved into others 3 in. larger; use similar proportions of loam, leaf-mould, and sand, but do not now sift the loam, merely breaking it by hand; press the compost firmly in the pots, and pinch out the points of the shoots, so as to induce them to throw out several breaks. Treat them through the summer as to heat and shade as already recommended, giving more air as the season advances; when the growth requires it, place in the pots several lat sticks, and round these wind the shoots, but do not allow them to twine to the sticks or each other, or they will cling so fast as to render them liable to be injured when removed. At the end of August cease shading, and also the use of the syringe, giving more air to discourage further growth and ripen up the wood. Keep them through the winter in a moderately light position in a temperature of 68° at night, with a few degrees more during the daytime, but do not allow the soil to ever become so dry as in the case of subjects that produce smaller leaves of a harder texture. By the beginning of March raise the night temperature 5° and 10° with sun-heat during the day, at the same time moving the plants into their blooming pots; these should be 15 in. in diameter, with a couple of inches of crocks in the bottom, covered with fibrous material to prevent the soil being washed down by the large quantities of water which they will want almost daily throughout the growing season. At this potting use the soil in a more lumpy state than formerly, add one-fifth of rotten manure and leaf-mould in equal proportions, and a fair amount of sand. Use the potting lath freely, so as to make the whole moderately solid. The plants should now be placed where they are intended to bloom; if to cover a pillar or rafter, they should at once be trained in such a position. There is no place that they can occupy with more advantage than running lengthways over a pathway in the stove; so placed they economise space that is seldom filled, and are in a good position for their flowers being seen to advantage. Such a situation gives an excellent opportunity for a free use of the syringe, so as to get the water to the leaves on all sides. This is necessary, otherwise red spider is sure to become troublesome. There is nothing better to train the shoots to than thin strings placed 6 in. apart, on each of which allow a single shoot to twine. As

the days lengthen, raise the night temperature to 70° or 75°, according to the state of the weather, with 10° more during the day. As the pots get filled with roots, an abundant supply of water will be required. They will now grow apace, and, by the middle of June, will most likely show their flowers, which are produced from the axils of the leaves over a considerable extent of the growing shoots. The plants may either be allowed to go on flowering through the summer where they are growing, or, if desired, the string may be cut, and the shoots wound round several sticks, inserted inside the rim of the pot, or a wide trellis may be used on which to train them. In this way, if wanted, they can be placed for several weeks, whilst the weather is hot, in the conservatory—first preparing them for the change by putting them at the coolest end of the stove, where they will receive more air than where they have been growing. Whilst in a cooler house, keep them well off the openings through which air is admitted; otherwise a check may be given to the advancing flowers that may cause them to fall off before opening. When the blooming is over, remove them back to the stove, placing them at the coolest end, and admitting sufficient air to ripen up the wood, and discourage further growth by giving no more water than is needed to prevent the leaves flagging. Winter in a similar temperature to that before advised, and by the end of February cut the shoots back to within about a yard or 4 ft. of the base of the plant; give a little more heat, and, when the young growth are a few inches in length, turn the plants out of the pots, and remove as much of the old soil as can be got away without injuring the roots; place them in pots 3 in. larger than those they occupied, and treat them in every way through the spring and autumn as recommended for the season previous. Cut them back freely each spring to within a few joints from where they were shortened to the preceding spring, and partially remove the soil at potting-time; they will not need larger pots, but should, through the early part of summer, be freely supplied with manure-water; in this way the plant will last for years. When required to cover a considerable space they may be planted out, but even in this case they should not have too much root-room, or there is no keeping the larger-growing varieties within bounds without having to use the knife so as to seriously interfere with their flowering. The following are all fine kinds which differ considerably in their strength of growth, but all thrive in similar soil, and in other respects require the same treatment:

A. ornithocephala.—This is a native of Brazil; its flowers somewhat resemble a bird's head in shape, and have a pale yellow ground, covered with a network of blackish purple; a very handsome sort, and one which blooms in June and following months; suitable for either pot specimens or rafters.

A. Gigas.—A very strong-growing species, from Guatemala, with a good deal of the flower of a palish purple; blooms in July and August; only suitable for a pillar or rafter.

A. galeata.—A free-growing species from Bogota, with cream-coloured flowers, covered with purple veins.

A. floribunda.—This is a native of Northern Brazil, from the Amazon district; it is a plant of medium growth, producing a profusion of flowers—in colour, a combination of yellow and reddish purple; it is very suitable for growing as a trained pot specimen, not being too strong and rampant in growth. It is not yet much known, and from the locality it is introduced from may very likely do with less heat than the other species, which would make it doubly valuable as a decorative plant.

Insects.—Aristolochias are not so much troubled with insects as many other stove plants, except red spider, which in hot summer weather will soon injure the leaves and make them unsightly if the plants are not regularly and freely syringed. Brown scale and mealy bug will sometimes make their appearance, but can be removed by sponging and syringing. The yearly heading down also gives an excellent opportunity for washing the stems with a strong solution of insecticide when at rest.

T. BAINES.

The Harbinger Wallflower.—Plants from seeds of this sown in February, and grown on in pots through the summer, will, by the end of September, be full of flower-buds, and may be had in bloom all through the winter. The colour of the flowers is a fine lively red.—RICHARD NISBET, *Ascacby Park*.

THE FLOWER GARDEN.

THE PRIMROSES.

By J. C. NIVEN, Botanic Garden, Hull. Illustrated by F. W. BURBIDGE.

THERE is a charm about a bank of Primroses which no other flower possesses, possibly on account of early associations, and rarely do we find the Primrose unaccompanied by its modest companion, the Violet, whose deep-blue flowers peeping from beneath the foliage every here and there, set off the pure sulphur yellow of the Primrose to increased advantage. But the genus, the principal species of which we purpose passing in descriptive review, appeals to more than early associations. What a wealth of florist industry has in years gone by been devoted to the culture of the Auricula, in its green and grey-edged, as well as Alpine, forms! What extraordinary mixtures of soils are recorded as necessary to form the compost for its proper culture! It is true a lull in the florist's zeal has been for some years manifest as regards the cultivation of this plant; but the mantle of the old veteran, Dr. Horner, appears to have fallen on his son, who, from the heights of Kirby Malzeard, has raised his beacon fire, and issued the watchword of "onward progress." The revival of Auricula culture is sure to extend its influence to its relation the Polyanthus, which, doubtless, after years of neglect—sufficient to make the old standard flowers things of the past—will once again become popular. Nor do these two exhaust the florist's domain; has he not manipulated the old China Primrose from a pale flower deep-notched in every lobe to a glowing crimson, befringed and befrilled with charming irregularity? Nay, more, he has altered the very foliage in shape so much that were the long pinnate-leaved form, now so popular under the title of Fern-leaved—a fresh introduction from the east, it would, doubtless, lay claim to specific individuality. Then, have we not amongst them veritable gems of Alpine beauty, varying in colour and stature from the yellow giant of the Himalayan Mountains and its imperial relative on the mountains of Java, to the happily named *P. minima* of the snow-line of our Swiss Alps, or the bright-eyed Primrose of our Scottish hills, *P. scotica*? Where all are so lovely, it would be invidious to make distinctions. Nor is there a single species that is not worthy of a corner on the sunny slopes of the rock-garden; and some are so amenable to cultivation that they will find themselves perfectly at home in the front ranks of the flower border, or even beside the margins of woodland walks. In dealing, from a descriptive point of view, with a genus consisting of nearly 100 species and well-defined varieties, apart from those that have been originated by the hand of the florist, I am sure that it will be at once admitted that it is desirable to divide them into groups or sections.

- Group I.—Primroses, including our Primrose, Oxlip, Cowslip, and Polyanthus.
- II.—Auriculas, which will include all those that in form of leaf, flower, and habit of growth, have an affinity to the well-known Auricula.
- III.—The Farinose Section, which includes all those whose leaves are covered with a mealy substance, and which produce comparatively small flowers.
- IV.—The Oval-leaved Section, containing a limited number of small, but charming plants, with oval leaves.
- V.—The Denticulate Section, with long leaves, toothed at the margin, and producing dense heads of lavender-coloured flowers.
- VI.—The Giant Section, with long green leaves, tall farinaceous peduncles, and yellow flowers (*P. Parryi* excepted.)
- VII.—The Verticillate Section, to include all those whose flowers are arranged in verticils, or tiers one above another.

Section I.—Primroses.

P. vulgaris.—This is the now recognised botanical name of our old familiar friend, the Primrose; occasionally it may be met with in books under Allioni's specific title of *P. acutilis*. Its home may be said to be in Eastern Europe, and mainly also in our own British Isles. Any description of it, therefore, will be unnecessary, beyond the passing note that its flowers, if carefully examined, will be found

very frequently to originate from an undeveloped stem, so that the name *acutilis* was not by any means inappropriate. As regards colour, besides the true typical sulphur-yellow, we have mauve in almost every tint, occurring in what may be called a wild state; but wherever I have seen this digression at all pronounced in character I have, with tolerable certainty, traced its origin to some garden source—that is, to hybridity with some of our cultivated garden forms, and usually found that where they occurred there had been a garden in olden time, if not at the place itself, at least in the immediate neighbourhood. Besides these variations in colour, we have many double varieties, such as double yellow, double white, double purple, and double crimson, the latter the rarest of the lot in cultivation. I might here remark that these charming forms that were

Common Primrose (*P. vulgaris*).

went to abound in cottage gardens some years ago are neither as plentiful nor as vigorous in growth as they used to be. I have a sort of suspicion that the two or three consecutive dry seasons, which we had some years ago, and the more efficient drainage of the ground in connection with sanitary improvements have favoured the ravages of the red spider, than which no greater enemy to Primrose culture exists, and that these may in some measure account for their comparative scarceness. Besides these variations, we have in *P. vulgaris* var. *speciosa* (long cultivated as *P. altaica*, a perfectly distinct species), a plant possessing larger and coarser leaves, and large, deep mauve-coloured flowers so early in spring as almost to claim its position as one of our mid-winter flowers. Added to this, its leaves are produced so early in autumn

Double Primrose.

Coloured Primrose.

that by the time it blossoms they have acquired full development, and, as will be seen by the accompanying figure, the combination of leaves and flowers has a very pretty effect.

P. veris (the Cowslip), so universal in our English meadows, indulges in but few variations beyond that of the colour deepening from yellow into an orange-red; this, in some localities, is not at all infrequent, and my impression is that in this deep-coloured plant we may look for one of the parents of our garden Polyanthus. This conclusion I have come to from noticing that, in a very few years, the common red Cowslip can be arrived at from the Polyanthus by a sort of retrogressive selection, which decidedly requires less care and art than the more generally practised progressive selection.

P. veris var. *inflata*, though usually given the specific position assigned to it by Lehmann, is, in my opinion, nothing more than a variety with the calyx inflated rather than campanulate. It sometimes goes by the name of *P. macrocalyx*.

P. elatior (the Oxlip of Jacquin, with the aspect and general habit of the Cowslip), has flowers of a pale yellow, intermediate in size between the latter and the Primrose, which, to my mind, unmistakably indicate the hybrid origin of this plant. This matter, as assumed by me, has, I know, been disputed, the arguments against it being chiefly based upon the fact that, though in this country the

Oxlip.

Cowslip.

two species may be often seen flowering side by side, yet it is rare to meet with the intermediate species. This I at once admit; but, seeing that the very last blooms of the Primrose are passing away as the Cowslip comes into flower, and, further, that these latter flowers have all but abortive sexual organs, the rarity of the hybrid may more easily be accounted for than might have been supposed.

P. elatior var. *polyantha*.—Although I have already hinted that the origin of our garden Polyanthus is more traceable to those deep-coloured forms of the Cowslip than to the Oxlip, yet as it is usually recognised in catalogues as a variety of the latter, I will recognise it as such, as I think it not improbable that its true parentage may be traceable to the combined action of all the three named species, and hence its power of variation. Of this we have several double forms, as well as those varieties known by the popular title of "Hose-in-hose," the latter originating from a simple reduplication of the corolla, and we have also a form, though rarely met with, in which the corolla is absent altogether, and the various parts of the flower become metamorphosed into leaves; this, however, is more interesting from a morphological and botanical than from a horticultural point of view.

*P. elatior* var.

Section II.—Auriculas.

P. Auricula, or *Auricula Ursi* of old authors, a name given to it from the supposed resemblance of the leaves to the ear of a bear—a resemblance which, by the way, I have always failed to see—is an

The Auricula.

old-established favourite, and whether in grey or green-edged forms—which are really of garden origin—or in the true Alpine character, which I take to be the specific type, are alike desirable for cultivation.

The variety of colour, and also of the shape and character of the leaves, of a set of seedlings is something astonishing. Some will be smooth-edged and deep shining green, others dusted over like millers, and others, again, crimped along the edge with beautiful regularity. I may mention here as a singular coincidence that three years ago I planted out a lot of seedlings, saved from some selected sorts, in the spring; by the autumn they had become well-established plants, but, strange enough, every one that flowered in the autumn produced either double or semi-double flowers. My readers may guess how very anxiously I looked for the spring flowering, hoping that I had hit on a new strain—the more so as there was a plant of the old double yellow associated with those I saved my seed from; judge of my surprise when I say that in spring there was not even a semi-double one in the lot. Such admirable cultural directions have so recently appeared in your paper from Mr. Horner's pen that I need here do no more than commend this section to the attention of your readers.

P. viscosa, of Allioni, is not uncommon in cultivation under the name of *P. ciliata*, but, as it has the true viscosa character much more developed than the ciliated, I prefer adopting the former name. It is a dwarf, compact plant, with dark green leaves, toothed

The viscid Primrose (*P. viscosa*).

at their margins; the flowers are produced on short scapes, of a rosy-lavender colour, shading to white towards the eye, which is open—the corolla, in fact, assuming the funnel-shaped rather than the salver-shaped character of the old *Auricula*. It flowers in April, and is a native of the Alps and Prances.

P. viscosa var. *intermedia*.—A garden hybrid, in which the parentage of the *Auricula* is readily distinguished by the larger and smoother leaves, and the deep purple colour, with a well-defined white eye. Several other hybrids from the same source are now in cultivation, varying in colour, and notably distinguished from the *Auricula* by the denser character of the plant.

P. viscosa var. *nivea*, or, as it is sometimes called, *nivalis*, is even more dense in habit than the above. The leaves are broadly obovate, distinctly toothed towards the apex, becoming entire

White Alpine Primrose.

towards the base of the spatulate petiole; they are of a light green colour, covered with short villose hairs; the flowers are white, produced in dense clusters on stems usually so short that they appear to nestle in a mass amongst the foliage; they are funnel-shaped, with the marginal line of the corolla prettily undulated. It is a native of Switzerland. This must not be confounded with Fischer's Siberian *P. nivea*, which is a distinct species that I have never seen in cultivation.

P. decora and *pedemontana* are both natives of the Alps; both have their leaves covered with a very short pubescence; in the former they are broadly ovate and distinctly and deeply notched, the terminal lobe being large and pointed; whereas, in the latter, they are almost entire, with the point blunt; both are very dwarf plants, and almost stemless. The colour of the flowers in the former

is lavender, and they are produced in limited numbers on a short scape; in the latter, they combine a deep rosy tint along with the lavender, form massive many-flowered scapes, rising from the centre of the leaves to a height of 4 or 5 in. In cultivation, the former appears a much freer grower than the latter, which, however, is decidedly the showier plant of the two. Both are, however, desirable plants, and admirably adapted for inserting in the crevices of a rockery, where a little root moisture can be obtained in hot summer weather.

P. glaucescens, of Moretti, is synonymous with that frequently cultivated as *P. calycina*; here we have a series of perfectly smooth, entire, broadly ovate, and acuminate leaves of dark green colour, forming a rosetto from whence rises a short scape with five or six handsome funnel-shaped blossoms—remarkable for the extreme irregularity of their outline—their colour being a rosy-lilac. It is a native of the Italian Alps, and blooms with us in June. In ordinary

P. integrifolia.

P. glaucescens.

cultivation it is of very slow growth and a shy flowerer. Closely allied to this species and differing chiefly in the narrower leaves, and the more bluntly pointed calycine segments is the *P. integrifolia* of Jacquin, whose flowers, by the way, are of a dark purple, and much more regular in their outline. It is a native of the Mountains of Austria.

P. marginata, of Willdenow, is a plant well marked by the silvery margin that surrounds its ovately cuneate and sharply serrated leaves, as also by the greyish tint of the young leaves, owing to the presence of an abundance of farinaceous matter. The plant has a strong tendency to acquire a caulescent character, the stem rising well above the ground, and marked by the scars of decayed leaves. The flowers are produced freely in April in umbels elevated on scapes, some 3 or 4 in. long, and are of a lavender colour; it

Laced Primrose (*P. marginata*).

is a native of the Dauphiny and also of the Apennines; and although it may prove hardy in a sheltered corner of the rockery, it is not by any means to be depended upon in an open border. If cultivated close to the glass in a cool greenhouse, it forms a charming plant for spring decoration, and ought to be grown for that purpose much more than it is; it is partial to peat soil, and when it acquires the woody character to which I have alluded, it ought to have its branches cut short and inserted round the margin of a pot, rather than that any attempt should be made to bury the older portion. Under the latter conditions, very frequently decay from below takes place.

P. latifolia, of La Peyrouse, as the name would indicate, has broad somewhat pubescent leaves tapering down into a narrow foot-stalk; it possesses a caulescent character like the last, and is said to have rose-coloured flowers. With me, however, it is a shy grower, and though I have cultivated it for a good number of years, I have

had no opportunity of practically forming an acquaintance with its floral character. It is a native of the Pyrenees.

P. minima is one of Linnaeus's happy specific titles, as it is here applied to the most diminutive of all the Primroses, so far, at least as stature is concerned. The plant consists of a series of

Fairy Primrose (*P. minima*).

compact rosettes of wedge-shaped leaves, sharply notched at the ends into three or five lobes; the flowers are produced singly, almost sessile, large in proportion to the size of the plant, in fact, fully an inch across, of a very red colour. The limb of the corolla is deeply divided into five segments; these, again, are further notched, though not so deeply, and even the margins of these lobes are still more irregularly notched. It is a native of the highest altitudes on the European Alps, where it is found just below the line of perpetual snow. In cultivation it likes a well-drained gritty soil, and perfect firmness and solidity in the mechanical texture, and, above all things, it requires a watchful eye to guard it from slugs, which in a single night will gouge out the flowering core of each of the rosettes in the most deliberate manner possible.

P. Palinuri, of Petagna.—In this species we have an extreme contrast to the preceding, as here we have the giant of the section, a tree-like *Aricula*, and one which possesses at the same time a singu-

P. Palinuri.

lar resemblance in general contour to the arborescent forms of the *Sempervivums*. In Naples, its native country—in fact, I believe it takes its name from a Neapolitan promontory known by the title of *Palinurus*—it acquires the character of quite a diminutive tree; its stem is thick and fleshy, from 1 to 1½ in. in diameter, coarsely marked in the lower portion by the scars of the former foliage, the upper portion being well clothed with fleshy and somewhat leathery leaves, broad towards the apex, and gradually tapering down into a broadly spatulate foot-stalk. The flowers are produced from the apex of a farinaceous peduncle, that is developed from the axil of one of the lower leaves—not from the growing point, as might readily be assumed from the accompanying figure—in considerable numbers, and in varying stages of development, some being quite small buds, while others are fully expanded; the calices in every case are suffused with that mealy matter that we have already recognised as met with in some of our common yellow garden *Auriculas*. This progressive arrangement of floral development appears to harmonise admirably with the arborescent character of the plant. Though quite capable of enduring the severity of our climate with the protection of a cold frame, and possibly in the southern counties without even that, it ought to be looked upon as a plant worthy of a position in a cool house during the winter, where it will have an opportunity of producing and perfecting its early spring blooms,

and as a true arborescent type of the genus *Primula*, it has an interest whose appreciative value must not be weighed in the balance against more popular beauty.

III.—The Farinose Section.

P. farinosa (popularly known as the Bird's-eye Primrose) is one of those plants that gives a special character to the flora of the north part of Yorkshire, where I have seen it so abundant as to impress its charming pink colour on the surface of acres of mountain meadow, and where it might be gathered by handfuls 12 to 15 in. high. Its leaves are obovate and lanceolate, slightly crenulate, covered with resinous farinose matter, especially when young; the scapes vary in height, from 6 to 15 in., crowned with a dozen or more almost sessile flowers, of a lovely pink colour. The limb of the corolla is expanded, flat, and deeply and acutely notched in its segments. Under cultivation, it likes a soil in which peat predominates; but its growth is rendered more vigorous by the presence of a little loam, almost bordering on yellow clay, and some leaf-soil. One great point in its culture, as well as in that of scores of mountain plants, is to give moisture from below, rather than from

Bird's-eye Primrose (*P. farinosa*).

above. With a saturated subsoil, they will stand any amount of the hottest sun; but continuous drenching from the watering-pot causes them to rot off at the root, and this, not unfrequently, just as the plants are coming into bloom. The foliage perishes altogether in winter, when a small egg-shaped bud, with usually a few small offsets adhering to it, forms the winter character of this, and all the species in this section. The offsets, if removed just as growth has commenced in March or April, will develop into small flowering plants before autumn. It may also be increased by seeds, which it produces freely. They ought to be sown at once; for, if kept till the following spring, they often remain a twelvemonth in a dormant state.

P. farinosa alba and *acaulis* are two varieties; the former, as the name indicates, has white flowers, and is of exceptional occurrence; in the latter, the flower-stem is absent altogether, and the flowers form a dense mass in the centre of the rosette of leaves; this is an essentially distinct variety, peculiar to one or two localities in the North Riding of Yorkshire, where it was discovered some years ago by Mr. Backhouse.

P. scotica, the Scotch Bird's-eye Primrose, is of much smaller stature than the preceding, rarely exceeding 3 or 4 in.; its leaves

Scotch Bird's-eye Primrose (*P. scotica*).

are broader and more oval, smoother as regards the margin, and rather more densely covered with farinaceous matter; the flowers are smaller, of a deep purple colour, lighted up to intense loveliness

by a bright yellow eye. It is a rare Scotch plant, found only in the wild mountain districts of Sutherlandshire and in the Orkney Islands, and is even more lovely than the previous species, of which, by the way, some botanists maintain that it is only a variety, but surely it possesses ample distinctive character, alike in leaf, stem, and flower to claim a true specific title. It is particularly partial to a firm sandy soil intermingled with peat. It occurs elsewhere in Europe besides Scotland.

P. auriculata, sometimes called *P. magellanica*, bears a slight resemblance to *farinosa*, but it has broader and more undulated

P. longiflora.

P. intermedia.

leaves, and is more vigorous in growth; the flower-stems are about a foot high, and are terminated by a number of almost sessile flowers; the lobes of the corolla are deeply notched, and much more acute; the colour is combined pink and lilac, with a distinct yellowish blotch on the mouth of the tube; it is a free grower, and is a native of Hungary and Austria.

P. intermedia or *davurica*, as it is sometimes called, is a tolerably close relation to the preceding, the leaves are, however, smoother in outline; the scapes are shorter, and the flower-heads are more globose in character; it blooms in May, and will thrive well in any sunny corner of the rockery where a layer of peaty soil of some little depth has been previously made. It is a native of Siberia.

P. longiflora, of Allioni (not *longifolia*, which is a distinct species), brings our *farinosa* section to a close; its leaves are twice the breadth of those of any of the preceding species—broadly ovate and entire, with slight marginal undulations; the stem is about 8 in. high, terminated by a few flowers of an orange-red colour, which are subtended by foliaceous little bracts; the individual flowers are almost sessile, but separated from one another by the length of the tubes; the lobes of the corolla are widely parted, and each individual lobe is sharply bifid; the leaves, to a small extent, and the stem and bracts are covered with white powdery matter. It blooms in May or June, and is a native of the Swiss Alps, but rarely met with in cultivation.

IV.—The Oyal-leaved Section.

P. involucrata, gathered by Captain Munro at a high altitude (11,500 feet) on the Himalayas, where he found it associated with *Cyananthus lobatus*, has leaves in dense masses, the blades being oval and dark green, with a winged margin running down the sides of the

P. involucrata.

petioles; the flower-stems are about 6 inches high, terminated by three or four white, almost circular, blossoms, suffused with the slightest shade of lilac imaginable; at the base of the flowers are

several almost membranous bracts partially united together and reflexed downwards—a peculiarity that I believe belongs to this section alone.

P. involucreta var. **Munroi**, which has more fleshy leaves with emarginate points and larger growth, possibly may be nothing more than a local variation; both are readily propagated by division, numerous off-sets being formed at the base; they are perfectly hardy, and amenable to cultivation in any ordinary garden soil, the chief care necessary being to guard against their being smothered by ranker adjacent vegetation, as they are very diminutive. They flower both in May and in the autumn.

P. sibirica, of Jacquin, from the Altai Mountains, has oval entire leaves, but the pedicels are longer and more slender; nor does the plant form a dense mass as in the preceding species. The scape is 8 inches high, terminated by five or six nodding rosy-pink flowers, produced in April. This plant I have never seen in culti-

Siberian Primrose (*P. sibirica*).

vation, and it evidently possesses a delicate constitution—at least, such I should infer from the figure in the Bot. Mag.

P. norvegica, of Retzius, is the smallest of this group, its slender flower-stem only rising to a height of 2 in., terminated by two or three pretty white flowers tinged with violet; its leaves are oval, light green, and thin in substance, dying off almost before the full development of the flower-stem. It should be grown in pans immersed in water during the growing season, and kept moderately dry when it is at rest. I cultivated it for a few years and bloomed it, but found it a very misly plant to deal with. It blooms in June, and is a native of Norway and Finland. *P. fiamarchica* is a synonym.

V.—The Denticulate Section.

P. capitata.—This, the gem of this section, has narrowish lanceolate leaves, gradually tapering down to the base; the margin is minutely serrated through its entire length; the back of the leaf is silvery-white, owing to a coating of powdery matter, and the same character applies, in a modified degree, to the upper surface as well; it also forms a dense covering on the scape. This, in a vigorous plant, rises to a height of 10 or 12 in., and is terminated by a dense globose group of numerous small dark purple flowers, so closely arranged as to remind one of some of our Alliums. It was found growing by Dr. Hooker at high altitudes at Lachen, a pass between Sikkim and Thibet.

The seeds vegetated freely at Kew, and it was largely distributed, in hopes that some of the recipients might have been successful in seeding it; but, in no instance, I believe, was this success attained, the plants dying off after blooming. By an early removal of the flower-stems, we succeeded in retaining plants alive for three years; but they showed no tendency to increase at the root. I was in hopes that seeds of this lovely plant would have come to hand along with those of *Rheum nobile* and other Sikkim plants that have recently been re-introduced.

P. denticulata, a native of Silhet and Nepal, and various slightly modified forms, enjoying a wide distribution on the Himalayas, was introduced by Captain Madden and Dr. Royle about the same time; the seeds, however, were collected in two different localities, and gave rise to two distinct types of the same plant. One set, raised at Belfast, had the leaf margin recurved, and the whole plant covered with short down; the other, raised in Edinburgh, had smooth leaves, much and roughly corrugated, the margins irregularly serrated, less vigorous in growth than the Belfast one, and more elegant in its capitate masses of delicate pinky-lilac blooms, which are produced so early in the season that they are liable to be nipped by early spring frosts and cutting east winds; though perfectly hardy, it forms a charming addition to the greenhouse and conservatory during the month of March. I believe that the hairy plant is *denticulata* of Wallich, who especially alludes to pink fleshy bract-like processes that surround the dormant bud in its hibernatory

state; these are scarcely noticeable in the smooth plant. The latter, by the way, I believe to be identical with *P. Fortunei*, which was sent out some years ago as a Chinese plant. I cannot lay my hands on any description or figure of it; but my plant, which I got from an

*P. denticulata*.

orthodox source, is, undoubtedly, identical with the smooth-leaved variety of *denticulata*.

P. pulcherrima.—A provisional, but by no means inappropriate, name given to a plant raised by Messrs. Backhouse from seeds sent from the Himalayas as *P. denticulata* nana. Whether it should be recognised as a distinct species, or as an extremely handsome variety of the old species, may be questionable. To my mind, the more regular distribution of the veins, and the finer marginal denticulations of the leaves, as also the wider separation of the lobes of the corolla and the deep and acute notch in each of the lobes, appear to point out specific characters of some value. My impression is that it is a nearer ally of *purpurea* than *denticulata*, and takes a position intermediate between them. Be this as it may, it is a very handsome Primrose, with large, dense globose heads, whose flowers are lavender-coloured, with a suffusion of a pale yellow eye, which encircles the almost closed tube. This, like all the section (*P. capitata* excepted), likes a good stiff loam, moderately enriched with well-decayed manure. Messrs. Backhouse

*P. pulcherrima*.

state that it is perfectly hardy, and that it grows freely with them in either rockery or open border.

P. purpurea affects somewhat higher localities than *denticulata*, namely, the sloping sides of the lofty passes of the Himalayas, in the neighbourhood of Gossanthan, where it is associated with such species as *petiolaris*, *elliptica*, and *Stuarti*. Its leaves are larger and coarser than *denticulata*, with a thick, fleshy, red mid-rib, the margins irregularly denticulated and slightly recurved; its flowers are arranged in flattish globular heads, and are of a light purple colour. It is perfectly hardy, and has the advantage of blooming sufficiently late in the season not to be injured by our spring frosts. Hitherto an exceptionally rare plant, it has been recently raised abundantly from imported seeds, and we may hope to meet with it more frequently than it has been in our gardens and herbaceous borders, where its presence will be highly appreciated.

P. erosa has much the aspect of a diminutive form of *denticulata*; the leaves, which are slightly broader towards the apex, are irregularly sinuate, so irregular that the mind is impressed with the idea that their margins have been eaten away by snails or other undesirable intruders—hence the specific title; the flowers are pale lavender, supported on stems about 6 or 8 inches high. I take it as a matter of course that it is also a Himalayan plant, though I do not find it described in any of the botanical works I have by me.

P. longifolia, of the Hortus Kewensis, produces a mass of smooth light green, lanceolate, blunt-pointed leaves, of a hard consistency; the mid-rib is fleshy and pink-coloured towards the base; the stem is slightly farinose, and rises to a height of 6 inches; it is terminated by a dense cluster of small rosy flowers. Though not as showy as its Himalayan allies, it is interesting as a representative of the same type occurring on the mountains in Greece, and also on the Caucasian range. It is perfectly hardy, and flowers in May.

P. amœna, of Bieberstein, though introduced some fifty years ago, and recorded as a very handsome species, has long since disappeared from cultivation. Its leaves are long, broadly ovate, or, in fact, obovate, owing to the gradual narrowing of the blade towards the base; its flowers are purple and funnel-shaped, the tube being of a

*P. erosa*.*P. amœna*.

length nearly equalling the width of the corolla; the individual flowers are not sessile but supported on short foot-stalks, and, being developed in succession, not simultaneously, the inflorescence assumes a lax character, as compared with the other species, which we have recognised as belonging to this section. It is a native of the Caucasus, and is recorded as flowering in April and May.

VI.—The Giant Section.

P. sikkimensis.—One, and by no means the least valuable, souvenir of Dr. Hooker's botanical sojourn amongst the high mountain passes of the Sikkim Himalayas. This may well be taken as the typical plant of this section, for it is a veritable giant Oxlip. From an underground bud of comparatively small size, with a few radiating roots, reminding one of the North American *Dodecatheons*, rises a number of upright-growing leaves, oblong and obovate in shape, rugose, and twice serrated at the margins, hairless, and of a bright olive-green; from the centre of these rises a somewhat slender scape, to a height

Sikkim Primrose (*P. sikkimensis*).

varying from 12 to 30 in., suffused with sulphur-coloured farinose matter, gradually becoming more dense towards the upper part of the stem. The flowers are pendulous, being supported on slender foot-stalks; the calyx is covered with farinose matter, and the corolla, of a pale sulphur-yellow, is wide, expanded, and campanulate, showing little tendency to contract at the mouth of the tube; the bunches of flower, varying in development, remind one irresistibly of bunches of seals of light-coloured African gold. Added to the beauty of the flowers it has the fragrance of the old familiar Cowslip concentrated in the highest degree. Dr. Hooker describes it as growing so abundantly

as to give its special tint of colour to the Himalayan slopes at altitudes extending to even 17,000 feet. When growing luxuriantly it is the noblest of all the Primulas, but in order to ensure success it must have ample underground moisture and full exposure to the sun. The finest plants cultivated at Kew were grown in a bed devoted to aquatic plants, with a tank below that could ensure complete saturation and a corresponding perfection of drainage when required. I also remember being charmed with a group of it that occupied a projecting little knoll just raised above the water surface at Messrs. Backhouse's nursery when there were but few plants of it in the country. Recent arrivals of seed from Sikkim will render this valuable plant obtainable by all cultivators of Primulas, and to their notice I would specially recommend it.

P. imperialis is, I believe, the only Primula with which we are yet acquainted from the mountains of Java, and it is only known by description. It, however, appears to be equally gigantic in size, with yellow flowers, and certain structural peculiarities that have caused it to be given a distinct generic title. Let us hope we may soon be enabled to form a practical acquaintance with this interesting plant.

P. Stuartii, of Wallich, has been already alluded to as growing abundantly at Gossanthan along with *purpurea* and other species. It forms a noble plant, with somewhat fleshy erect leaves fully 12 inches in length, the margin sharply and minutely serrated; the scape is suffused with sulphury farinose matter, and the flowers are of a full canary yellow disposed horizontally; the lobes of the corolla are broad and emarginate, the length of the tube rather exceeding the width of the flower; the mouth of the tube is contracted. I fear much that there is no living plants of it in the country at the present time, unless, by the way, seeds have arrived along with those of the other Sikkim species previously alluded to. It is more than twenty years since I have seen it growing, and as it was a very shy seeder and did not produce off-sets readily, it appeared to be

Stuart's Primrose (*P. Stuartii*, B. M.).

in a fair way for becoming extinct. Wallich, who had not seen *P. Sikkimensis*, speaks of this species as the most striking of the Himalayan Primulas.

P. luteola is a strong, vigorous-growing species from the Caucasus, with smooth leathery leaves, margined with a series of small serratures, in appearance reminding one of *Senecio Doria* on a small scale; they are 9 to 12 in. long; the scape grows 12 to 15 in. high, is slightly farinose, and terminated by a dense mass of small yellow flowers. Though this has been some time in cultivation and is decidedly a distinct and well-marked species, I am obliged to plead guilty to a total ignorance of its history beyond the fact that I raised it from seeds some years ago obtained from Berlin. Possibly some of your readers may be able to supplement my remarks with some further information respecting it. It is, at any rate, a free and vigorous grower, and rejoices in a good stiff loamy soil subtended by a cool moist clay bottom.

P. Parryi.—One of the few Primulas that we have in cultivation from the New World; it is we believe a native of the extreme northern parts of the Rocky Mountains, and was first introduced some fifteen years ago by Mr. Thompson, of Ipswich. It is a vigorous grower with smooth broadly obovate leaves of a light green colour; the flower-stem, 9 to 12 in. high, is slightly farinose and terminated by a lax group of medium-sized flowers of a purple colour with a yellow centre. Though I possessed one of the original plants of this species, and kept it for six years, I never succeeded in blooming it; judging from descriptions it must be a very handsome and desirable plant for either rock or border culture. It has recently been reintroduced by Messrs.

Backhouse, else I question much whether it had not become altogether extinct; with me it appeared to be a shy grower and decidedly

P. Parryi.

disposed to grow less year by year, although I gave it several changes both of soil and situation.

VII.—The Verticillate Group.

P. cortusoides, of Linnæus, is an old and well-known plant from Siberia; its leaves are nearly as broad as they are long, lobed and cordate, rugose, rising from a scaly underground bud; the stem is smooth rising to a height of 12 to 16 in., sometimes terminated by a lax cluster of charming pink flowers; the lobes of the corolla are somewhat narrow, but when growing freely the first formed axis is supplemented by a second and even a third tier of flowers. It grows well in any garden soil, but, owing to the fact that it dies down below the surface of the ground in winter, it is liable to be destroyed in the operation of digging. It, however, seeds freely and may in

P. cortusoides (B. M.)

this case be readily increased; it flowers in May and a second time in August or September.

P. cortusoides amœna.—One of the most unhappy names ever given to a plant. In the first place, we have already had described a distinct species under the name of *P. amœna*. In the second place, I question very much if it be any variation of *cortusoides*; and being, without exception, one of the finest of all our Primulas, I think it is fully entitled to the honour of a specific distinction. When I saw it bloom for the first time, I christened it *P. macrantha*. Since that, however, I have come across a very brief description of one called *P. Sieboldi*, which, as far as it goes, appears to agree with our plant. Possibly, our friend Mr. Baker, of Kew, might be able to clear up this little difficulty for us, as he has done many others. The plant is distinct from *cortusoides*, especially in its rhizomatous style of growth, in its hairy foliage and stem, in its large pendulous flowers, whose wide expanded limbs are almost campanulate; and in its large calyx. Setting aside all technical description, it is one of the hardiest and most charming of our April and May flowers, varying in colour from pink to crimson, lilac, and white, with a tendency to a toned-down marginal line, and a lighter blotch down the divisional line of each corolline lobe. Thunberg records it as wild in Japan, but rare in its wild state. He, however, says it is largely cultivated; and that, under culture, it assumes many varieties in respect of colour. Possibly the Japanese florists may have manipulated this *Primula*, the same as ours have done the *Fuchsia*, *Geranium*, &c.; but, after

all, there is the distinct rhizomatous growth of the underground stem, which ought at least to have a value in descriptive botany. With me, it has never shown any indication of the verticillate character in the arrangement of the flowers; whereas the true *cortusoides* almost invariably does. Whether the Japanese have brought this plant up to its present state of perfection or not, I would strongly recommend it as an admirable basis for our florists to work upon; and I doubt not that its variations will be, at some future day unlimited.

P. mollis, of Nuttall, is a tender plant from the Bootan range of hills—hills they are called in comparison with the lofty Himalayas, but true mountains they would be were they removed from the immediate neighbourhood of their rivals. This, however, is a singular plant, as there is a certain amount of irregularity in its floral development, which is almost exceptional in the Order Primulaceæ. Its leaves are cordate, and almost palmately-lobed, covered with soft downy hairs, and reflexed at their margins; the flowers are arranged in verticillate, and are of a deep rose colour, the stems reaching a height of 12 to 15 in.; the calyx is intensely crimson, acutely divided, the corolla expands at a slight angle with the tube, and the segments are unequal, hence the irregularity I have already alluded to. Though not sufficiently hardy to stand our climate, it is a very desirable greenhouse plant, flowering abundantly in April, May, and June, after which it should be divided and placed in a close cold frame till it has commenced to grow, when it may again be potted into its flowering pots for the succeeding season.

P. sinensis, of Lindley, is synonymous with *P. prænitenis* of Kerr, as figured in the Bot. Reg. I prefer Lindley's name, as we are all so familiar with its popular title, the Chinese Primrose, which

P. sinensis.

P. sinensis var.

it embodies. So familiar, indeed, are we with the plant, and so thoroughly appreciated is it as one of our most useful winter decorative plants, that any description from me is unnecessary; nay, were I to give one in accordance with the original plant, I fear much whether my readers would recognise in it the compact, fringed, highly-coloured, double, and semi-double plants which, thanks to our horticultural friends, have long since superseded the old type introduced in the year 1821. I may, however, remark that there appears to be a doubt as to whether it is really a wild plant in China; at least, a short time back, there were no specimens from any recorded localities in that country in our herbaria; the supposition was that it was a Siberian plant introduced into China and largely cultivated there. Its tenderness will, I fear, militate against this supposition. The original *P. sinensis*, with its lax growth and verticillate arrangement of flowers, is well represented in the accompanying engraving, as is also the dense form known by the title of *erecta*, in which the verticillate tendency appears to have been entirely overcome.

P. japonica, introduced some years ago by Mr. Bull, is a vigorous-growing plant, with broad obovate and double serrated leaves, fully 12 to 14 in. long, and 4 in. across at the widest part, of a light green colour, with a pinkish mid-rib; from the centre of the large rosette of leaves rises the flowering-stem, producing in succession five or six tiers of flowers, of a deep crimson, and about the same size as those of our *Polyanthus*, but not so contracted at the mouth of the tube. As regards colour, there are many variations, and possibly this may prove a very useful plant for hybridisation. The large summer leaves gradually die away towards winter, leaving a fleshy bud of considerable size, containing, besides the embryonic leaves, the flower-spike, both of which become fully developed in the following spring. It is a handsome plant; but as, long before the top-most flowers are developed, the lower ones have withered away, the supplemental tiers are not of much value; moreover, its beauty is of but short duration. I believe it is hardy, but liable to decay from the excessive damp which frequently characterises our winters. It

seeds freely; but, even if some seeds vegetate the first year, the contents of the seed-pan ought never to be thrown away, as generally the second year produces a more prolific crop than the first. Plants from seed are much more vigorous growers than those produced by a division of the roots; the latter process of increase ought only to

Japan Primrose (*P. japonica*).

be used in the case of some special character as regards colour, that is not likely to be perpetuated by means of the seed.

P. verticillata, of Forskahl, an Arabian traveller and botanist. This is a very distinct species, with smooth, broadly obovate, serrated leaves; the blade decurrent into a tolerably well-defined petiole; the whole slightly diffused with farinose matter, which becomes more developed in the stem, and still more so in the broad foliaceous bracts which immediately subtend the flowers; the bracts decrease in size, and the flowers in number and length of foot-stalks, as the verticils succeed one another, giving the whole plant a pyramidal outline, whose apex, in a fairly vigorously grown specimen, will reach a height of about 12 in. The flowers, which are fragrant, are small, with a well-defined tube of a clear bright yellow colour. Coming, as it does, from the river-sides in the Arabian mountains, as might be naturally expected, it is not hardy, but forms a very pretty plant for greenhouse decoration, under which conditions it blossoms in April or even earlier.

P. verticillata var. abyssinica is a more fully-developed form of the old plant, larger in foliage and flower than the specific type, and far more densely covered with farinaceous matter. As the name indicates, it is a native of the mountains of Abyssinia, where, by the way, we find many of the Arabian plants indigenous.

To the above list might be added many more *Primulas* from the Caucasus, Siberia, and Turkistan, recently discovered and described by Dr. Regel, as also new species from the Alps; in connection with the origin of some of the latter there appears to be a doubt as to whether hybridisation has not performed an important part. Once the typical specific strain is broken, the variations and vagaries, even in a state of Nature, are endless, but as some of them are only known by dried specimens and equally dry descriptions, and others have only recently made their public appearance, I feel that they are better relegated to some future analyst of the genus, when a more perfect knowledge of their general characters under cultivation will have been ascertained. I cannot conclude this article on *Primulas* without expressing a hope that some of your contributors who have become familiar with them in their native habitats will kindly supplement my remarks with some of their own called from Nature's fountain-head. For my part, all I can pretend to do is to record results derived from my own cultural and practical experience, which is what I have done.

Festuca viridis for Edgings.—This is more compact than *F. glauca*, and makes a better permanent edging; its growth is small and neat, and it needs no trimming except cutting the flower-stems once in the summer. The stronger-growing *F. glauca* is admirably suited to form edgings in herbaceous, Rose, American, or wild gardens. Its growth is drooping and dense, and it is a much more appropriate plant for the purposes just named than many plants commonly used in that way.—A. D.

Delphinium formosum useful for Cutting.—This is a valuable plant when cut flowers are in request. It comes true from seed, and if sown early flowers the first year. It is, however, most satisfactory treated as a biennial. If the seed be sown during summer good plants are produced by winter, and if planted out as soon as growth commences in spring they yield a constant succession of their beautiful blue spikes during the whole season.—JAMES GROOM.

PLATE V.

ÆTHIONEMA GRANDIFLORUM.

Drawn by H. HYDE.

THE beautiful *Æthionema* here figured, drawn from a spray gathered in the Wellington Nurseries last summer, offers an opportunity to enumerate the many beautiful species of the genus, only a few of which are yet in cultivation. The subject of our figure is one of the most beautiful rock plants introduced of late years, forming compact bushes a foot high, and thriving on the level ground even in London. The following account includes the plants sometimes called *Iberidella* and *Eunomia*. Although this Cruciferous genus is even now comparatively little known in our gardens, two species, at least, were cultivated in this country about a century ago under the name of *Thlaspi*; but it was not till 1812 that Robert Brown described *Æthionema*, in Aiton's "*Hortus Kewensis*," for the species in question, namely, *Æ. saxatile* and *monospermum*. These are both natives of Europe, and by no means so showy as *Æ. grandiflorum* and several others briefly described below. Subsequent discoveries, chiefly in Asia Minor, Syria, and Persia, have augmented the number of species to about fifty, if we follow Boissier's "*Flora Orientalis*" for the limits of the genus. Several of them have been raised in botanic and private gardens from time to time, but again lost from neglect or unskillfulness; but now that the culture of Alpine plants is better understood, we may expect the really ornamental species to become more widely diffused. *Æ. cepeaefolium* and *Æ. cordifolium*, both very attractive dwarf rock plants, were figured in the "*Botanical Magazine*" a few years ago; and these, together with the subject of our plate, sufficiently illustrate the ornamental character of the larger-flowered species of the genus. The geographical range of the genus is from the Pyrenees to the Western Himalaya. There are, perhaps, half-a-dozen in Europe, including the beautiful *Æ. cepeaefolium*, better known as *Hutchinsia rotundifolia* and *cepeaefolia*. One only reaches India, where it is found at an elevation of from 12,000 to 16,000 feet, and the remainder are natives of the countries indicated above. Nearly all the species are natives of Alpine regions, and grow naturally in stony or rocky places, and many of them are reported from chalky districts. *Æ. pyrenaicum* possesses a striking resemblance in habit, foliage, and mode of growth to *Polygala vulgaris*, and is found associated with such plants as *Osyris alba* and *Passerina dioica*. The perennial species will, therefore, require to be kept tolerably dry at the root; a light soil in a well-drained border, or a place in the rock garden, will best suit them. Old plants should be replaced by young ones as often as convenient. These may be raised from seed or cuttings, which is better done in a cool frame or pit. The annual species, excepting *Æ. Buxbaumii*, are not, so far as we know, in cultivation. In habit and foliage *Æthionemas*, especially the half shrubby species, have very much the aspect of some of the woody *Candytufts*, but the petals are all equal in size. The seed-vessel seems to afford the best character by which the species may be distinguished. This is usually, more or less, broadly winged, as in *Thlaspi* and the Shepherd's Pursue, but the wings are usually concave, not flat, forming a boat-shaped seed-vessel. The margin of the wings, too, is often toothed or fringed. The flower-spikes are usually very dense, and the seed-vessel relatively large, and very much crowded, so that in some species, as *Æ. Buxbaumii*, they bear some resemblance to the catkins of the common Hop. The flowers are usually some tint of red or lilac, or combination of the two. A few species have yellow flowers, and there are white-flowered varieties of several species. About fifty species are known, all natives of the mountains of Europe, Asia Minor, Syria, and Persia.

Section I.

1.—Leaves auricled at the base, or hastate.

† Sub-shrubby Perennials.

1. *Æ. cepeaefolium*. (Bot. Mag., t. 5749, under *Iberidella*; *Hutchinsia rotundifolia*, Hort. Kew., Edition 2, Vol. IV., p. 82).—A densely-tufted, more or less glaucous-green, glabrous herb, with a long perennial tap root, that burrows deeply amongst stones. Stems, 3 to 6 in. long, ascending; leaves, mostly opposite, small, fleshy, one-third to three-quarters of an inch long, those from the root

BUSH ÆTHIONEMA. (Æ GRANDIFLORUM)

broadly obovate or almost orbicular, quite entire, or obscurely toothed, those on the stem sessile, obtuse, or auricled at the base; flowers, half-an-inch in diameter, in cylindrical, crowded, erect racemes, pale lilac with a yellow eye; pedicels, horizontal. A native of the Alps of Europe, where it is widely dispersed, and abundant in many parts of Switzerland. It is found at an elevation ranging from 6,000 to 9,000 feet. This is certainly one of the finest species of the genus. It was first introduced about 1759, and again recently; the plate in the Bot. Mag. appeared in 1859. There is a white-flowered variety of this in Kew Herbarium. As there is another *Æ. rotundifolium*, we adopt here the name of *cepefolium*.

2. *Æ. trinervium*.—Leaves, hard, more or less distinctly three-nerved, oblong or narrowly lanceolate, the lower ones narrowed at the base, upper ones obtusely heart-shaped and stem-clasping. Flowers, rather large, white, seed-vessel oblong linear, rounded or truncate at the top, crowned with the equally long style. Mountains of Persia. There is a variety of this species, called *ovalifolium*, with broader ovate-oblong leaves. It is a native of Armenia.

3. *Æ. sagittatum*.—Leaves, rigid, many-nerved, oblong, or lanceolate, deeply hastate at the base, with acute lobes; flowers, rather large, white; seed-vessel, oblong, narrowed at the base. Persia.

†† Tufted perennials.

Æ. tonus heterophyllum and *cepsitum* are dwarf, densely-tufted Alpine species, with small white or pink flowers. The only Indian species, *Æ. Andersoni*, also belongs to this group. It is a diminutive plant, with white or pink flowers.

4. *Æ. rubescens*.—Leaves, alternate, obovate; flowers, large, rose; seed-vessel, elliptical, tapering at both ends. A native of the Alpine summits of the Sicilian Taurus, &c., at an elevation of 11,800 feet. This is a very showy species, exceedingly like *Æ. rotundifolia*.

5. *Æ. Bourgæi*.—Leaves, opposite, obovate; flowers, large, rose; seed-vessel, oblong-elliptical, rounded at both ends. Found in stony places in the Alpine region of Mount Aklagh, Syria. Differs chiefly from the last in its opposite leaves.

Section II.

1.—Perennial, tufted with slender little stems; leaves, opposite, orbicular, fleshy (*Ennomias* of De Candolle).

6. *Æ. chloræfolium* (Iberis, of Sibthorp & Smith).—Leaves, slightly papillose and scabrid at the margin; flowers, rather large; petals, obovate, rose, much longer than the calyx. A native of Asia Minor.

7. *Æ. oppositifolium*.—Margin of the leaves naked otherwise, very similar to the last. A native of the summit of Mount Lebanon.

8. *Æ. rotundifolium*.—Very near *Æ. oppositifolium*, differing chiefly in the shape of the seed-vessel, and the panicle being free instead of adnate to the seed. A native of stony places in the Western Caucasus. This is quite different from *Iberidella rotundifolia*, described under Section I.

2.—Sub-shrubby perennials.

† Seed-vessel, one-celled and one-seeded.

9. *Æ. thesifolium*.—Stems, tall, slender, and twiggly; leaves, long, narrow, lanceolate, upper ones, acute; flowers in an elongating raceme pink. A native of stony places in the mountains of Pisidia and Cappadocia. This is the only ornamental species of this sub-section. It grows about 18 inches high, has long narrow leaves, and large flesh-coloured flowers, elegantly marked with purple. The other species are:—*Æ. elongatum*, *Szowitzii*, and *stenopterum*, all natives of Persia.

†† Seed-vessel, two-celled; cells, one-seeded.

10. *Æ. grandiflorum*.—Branches, long, slender, simple, about 1 foot high; leaves, oblong-linear, rather obtuse; flowers, purple, as large as those of *Arabis alpina*; petals, four times as long as the sepals. A native of Mount Elburus in North Persia; discovered by Hohenacker in 1843, and subsequently collected by Haussknecht, in Kurdistan, at an elevation of 4,000 feet in 1857.

11. *Æ. pulchellum* (*Æ. cordifolium*, of Botanic Gardens, not of De Candolle).—Similar to the last, of which it was formerly considered a variety; but it is a more diffuse plant, having smaller flowers, the petals being about two-and-a-half times as long as the sepals. A native of Armenia, Pontias, Persia, and Kurdistan.

12. *Æ. membranaceum*.—Stems, erect, simple, about 6 in. high; leaves, oblong-linear, smaller than those of the two preceding. The seed-vessel of these three species is very broadly winged, and the wings are entire, or very slightly toothed, at the margin. A native of Persia; formerly in cultivation in this country, and figured in Sweet's "Flower Garden." It is much less showy than either 10 or 11.

13. *Æ. diastrophis* (*Diastrophis cristata*).—In habit, foliage, and flower, this comes very near to *Æ. pulchellum*, but it differs from that and others of this sub-section in its very long fruiting racemes and small seed-vessel with elegantly toothed wings. It is a native of Russian Armenia, and was in cultivation at Durpat in 1841, and Paris in 1851, as specimens in Kew Herbarium testify.

14. *Æ. armenum*.—This, judging from dried specimens, although smaller-flowered than its immediate allies, must be a very pretty species when growing. It is of dwarfer (3 or 4 in. high), more diffuse habit, with more leafy stems and dense spikes of small purplish-rose flowers; seed-vessel, crenate. It inhabits the mountains of Armenia, Cappadocia, &c., growing in stony places.

15. *Æ. cordifolium*.—Stems, numerous, thick, only a few inches high; leaves, crowded, short, linear-oblong, or linear-obtuse, or somewhat acute; flowers, large, but not equaling those of *Æ. grandiflorum*; seed-vessel, boat-shaped. This handsome species is a native of the chalky summits of the Lebanon and Taurus, and was figured in the Bot. Mag. a few years ago, t. 6952.

16. *Æ. capitatum*.—This species, of about the same stature as the last, but with longer stems and more scattered leaves, is remarkable for its short dense fruiting heads of boat-shaped seed-vessels with entire wings; the flowers are small and inconspicuous. Alpine region of Cappadocia.

17. *Æ. speciosum*.—A densely-tufted species with ovate-oblong leaves, and rather large rose-pink flowers; seed-vessel elegantly toothed, and tinged with purple. A native of Armenia, and not yet introduced. It is described as one of the prettiest of the genus, growing in dense tufts 3 to 4 in. high, and producing a profusion of large flowers. *Æ. lignosum*, *subulatum*, *stylosum*, *lacerum*, and *fimbriatum* belong to the same group. They have rather small flowers, but in all of them the seed-vessel is very elegant. The three last have broad, ovate, or ovate-lanceolate, glaucous, somewhat fleshy, leaves.

††† Seed-vessel, two-celled; cells, one-seeded.

18. *Æ. cordiophyllum*.—Stems, few, rigid, densely leafy; leaves, rigid, quite sessile, deltoid-cordate, the lobes embracing the stem, the lower ones opposite; flowers, rose-pink, of medium size; boat-shaped seed-vessel, toothed. A native of Armenia, &c. This plant grows from 6 to 12 in. high, with leaves very similar to, but smaller than, those of *Polygala cordata*.

19. *Æ. cordatum*.—Stems, few, rigid, densely leafy; leaves, sessile, deltoid-cordate, acute; flowers, rather large, sulphur-yellow. A native of dry, rocky places in the Alpine region of Armenia, Syria, &c. It is similar to the last, but differs in its larger yellow flowers, and less distinctly toothed seed-vessel.

20. *Æ. salmianum*.—This is also a yellow-flowered species, and is very near the last, but it has heteromorphous leaves, and the wings of the seed-vessel are entire. Persia; found growing in stony places in the province of Aderbidjan.

21. *Æ. moricandianum*.—Stems, few, short, and leafy; leaves, all opposite, nearly sessile, ovate, obtuse, the upper ones sometimes cordate at the base; flowers, large, yellow. A native of Mount Caira, where it was discovered by Cinar in 1843. This species comes very near to *Æ. cordatum*, differing in its obtuse leaves, which are all opposite and scarcely cordate, and in its flowers, which are twice as large, equaling those of *Arabis alpina*.

3.—Perennial, but often flowering only once; seed-vessel, two-celled; cells, two and three seeded.

22. *Æ. græcum*.—Stems, numerous, short; leaves, crowded, very small, ovate-oblong; flowers, rather large, similar to those of the European *Æ. saxatile*, but twice as large. A native of the chalky mountains of Greece, &c. There are several others of this group, as *Æ. saxatile*, *gracile*, *ovalifolium*, *monospermum*, and *pyrenaicum*, but none of them are very showy, though all are pretty.

4. ANNUALS.—Seed-vessel, two-celled; cells, two or three-seeded or one-celled and one-seeded; fruiting spikes, very dense, often profliferous from the top.

23. *Æ. cristatum*.—Lower leaves, ovate or oblong petiolate, those on the stem sessile, cordate, and rather acute; flowers, very small rose or white; wings of the densely-crowded seed-vessels deeply jagged and toothed. This species is widely dispersed, from Armenia and Syria to Afghanistan, growing in a great variety of soils and situations. This group, to which *Æ. heterocarpum*, *Buxbaumii* and *campylopterum* belong, is more remarkable for the fruiting spike than the flowers of its species. *Æ. Buxbaumii* was introduced in 1823, and is occasionally seen in botanic gardens.

Taking a selection of the species described above, the following are among the most ornamental.—*Æ. cepefolium*, *cordifolium*, *grandiflorum*, *speciosum*, *moricandianum*, and *cordatum*.

W. B. HEMSLEY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Striking Cuttings.—Amateurs, in their first attempts at propagating, are often at a loss how to proceed. The question is, therefore, frequently asked, "In what condition should the shoots be of which the cuttings are made?" To this question no positive answer can be given, inasmuch as cuttings of one particular kind of plant may strike best in a comparatively soft state, while those of another may require to be made of better-ripened wood. For instance, cuttings of Pelargoniums, although comparatively quick-growing plants, should be made of tolerably well-ripened wood, or they are liable to rot, whereas many plants are indifferent as to whether the wood is soft or hard; but, in the latter case, the after-growth is never so free or rapid as when the cuttings were younger and softer. The necessity of, in all cases, as far as possible, selecting shoots for cuttings in the right condition as to ripeness, will, therefore, be obvious. For all such plants as Fuchsias, Heliotropes, Verbenas, Petunias, Lobelias, Ageratums, and Lantanas, that are usually struck in winter and early in spring, the cuttings should consist of quite young soft shoots, taken off with two or three joints, according to the strength of the individual shoot. In most cases it is best to sever the shoot immediately below a joint, which should form the base of the cutting; although there are some plants, such as Verbenas and Lobelias, that will emit roots freely from any part of the stem. A joint at the bottom is, however, to be preferred. The soft young shoots of Dahlias, for example, taken off when about 6 in. long, with a joint at the base, strike readily. Azaleas, Bourvardias, Acacias, Genistas, Daphnes, and Cassia corymbosa strike best from cuttings made when the wood is about half ripe—that is, when the current year's shoots have attained nearly their full thickness, but are not more than half matured. Hydrangeas and Oleanders root freely, when the shoots are young and comparatively soft, or when the growth is approaching maturity with the buds formed in the autumn. Cuttings of Lasiandras, Kalosanthos, and Pleromas strike readily from half-matured shoots. Amongst plants that require stove-heat in which to grow, such as Allamandas, Aralias, Dipladenias, Jasminums, Bougainvilleas, Euphorbias, Apelandras, Poinsettias, Aristolochias, Passifloras, Clerodendrons, Crotons, Cyanophyllums, Cyrtoceras reflexum, Francisceas, Plumbago rosea, Sericogynis Ghiesbreghtii, and Sphaerogynes, all root freest when made of young shoots from 6 to 8 inches in length taken off with a heel—that is, with the firm portion of the bottom of the shoot, at its juncture with the old wood, attached to them. Many plants, difficult to strike, will root with very few losses in the shape of cuttings taken off in this way, provided they are severed from the plant with a thoroughly sharp knife, that will make a clean cut, without in any way bruising the bark. Tabernamontanas, Stephanotis, Rondeletias, Pentas carnea, Meyenias, Medinillas, Ixoras, Hoyas, Gardenias, Eranthemums, Centradenias, and Æschynanthus readily root from half-ripened shoots. The above are some of the plants grown under glass, in the propagation of which amateurs are most likely to experiment, and with which, after a little practice and observation, they will be most likely to succeed. It is, however, in all cases, necessary to bear in mind that when a cutting is severed from the plant that has produced it, the source from which it hitherto has been sustained is at once cut off, and that, until roots are formed, it is necessary to keep the soil continually moister than would be required in the case of a growing plant of the same species. This holds good with all plants that are not of a very succulent character; these, if the soil be kept wet before the cuttings have become calloused, are liable to rot. In order to diminish the loss by evaporation in cuttings two expedients are resorted to, viz., removal of a portion of the leaves and enclosure of the cuttings under propagation-glasses or close frames, together with shading from sunshine; but, although it is necessary to thus surround cuttings of most plants with a confined moist atmosphere until they have formed roots, care must be taken that the air in which they are confined is not kept too close and moist, or they will damp off. To prevent this the glasses or frames should every day be slightly raised according to the state of the weather and time of the year; in dark dull weather, when the days are short, the lights will bear tilting more than would be advisable when the season is further advanced and when there is more sunlight. As much air may always be safely given to cuttings as they will bear without causing the leaves to flag; this refers to almost all plants that amateurs are likely to attempt propagating. Pelargoniums form an exception, inasmuch as they do best uncovered by glasses or propagating frames. As to temperature it will usually be found that cuttings of all plants require as much heat to induce a free production of roots as that to which they are subject in their native country during the growing season. In the selection of cuttings generally from plants of all descriptions, weak shoots should be avoided; these, even under the best treat-

ment, in the after stages of their existence, can rarely be made to equal such as are stout and freer in growth. The stronger the cutting, as a rule, the stronger the plant. On the other hand, gross over-vigorous shoots should not be chosen, as these are liable to damp off. There is another matter of importance in the propagation of plants of all kinds, and that is, they ought as far as possible to be potted off as soon as they are well rooted, for if numbers of cuttings be struck in one pot or pan, and then allowed to remain for some time after they are rooted, the roots get interlaced to such an extent as to cause serious breakage in getting them asunder; and if allowed to stay long in the cutting-pot, they do not receive sustenance sufficient to keep them in a healthy growing state, consequently they become stunted, the result of which is that a considerable time elapses after they are potted off before they can be induced to grow, and in many cases they can never be got to make good plants.

Greenhouses.

Pelargoniums of both the large-leaved and fancy kinds that had the points of their shoots pinched out some time back, and have since broken, should now receive a shift into pots to suit the size and vigour of the plants. Pelargoniums delight in a good, rich, unctuous loam, that has been cut from an old pasture and laid up for a time so as to destroy the herbage; and, where this can be obtained, there is no difficulty in growing them to perfection. In potting, ram the soil into the pots around the old ball as firmly as possible, using a properly-prepared flat piece of wood for the purpose; and, in doing so, great care must be taken that the tender roots surrounding the ball do not become bruised or injured. In the case of old plants that have been cut back, it often occurs that the young shoots become too crowded to admit of all being retained, and, therefore, any that are weak or can be spared should be cut out to afford the necessary light and room to the others so that they do not become drawn. Any shoots of sufficient length to admit of being trained should be drawn down so as to make the frame of the plant as large as possible. A few pegs made of small galvanised wire answer the purpose admirably, or a strand of matting run round the pot just below the rim for the purpose of threading other pieces through with which to tie down the branches, will answer for all purposes of training at present. See that aphides do not effect a footing on them, or they will soon disfigure the plants and cripple their growth. When potted place them on shelves or in some other favourable position where they can enjoy plenty of light and sunshine. Spot, that fatal enemy to the health of Pelargoniums, is generally brought on through the plants being placed in unsuitable positions, where they get an insufficiency of light and warmth, accompanied by too damp an atmosphere. A temperature of 45° by night should therefore be maintained to do them well, which may be allowed to rise to 55° or so when the days are bright and clear, so that a little air may be admitted. In doing so, at all times avoid cold draughts and cutting winds. Calceolarias, both shrubby and herbaceous, can scarcely have the atmosphere too damp, and it is therefore difficult to treat them in the same house with Pelargoniums and other things requiring a drier atmosphere. Where this cannot be done, place them in positions where they can have the syringe drawn lightly over them without interfering with the other occupants of the house. Herbaceous Calceolarias should never become pot-bound or receive a check in any way. Keep them steadily growing on by shifting into fresh pots as they require it, using a somewhat lighter soil than that advised for Pelargoniums, and potting them less firmly than the latter require. Old plants of the shrubby varieties, such as Kayii and others, taken up and saved from the borders, make very showy useful plants when potted and nursed on through the winter. Almost any damp pit or frame will suit these, and they are sure to be acceptable when laden with their rich heads of bloom. Old plants of Fuchsias should now be placed in any forcing-house at work, or where they can get a gentle moist heat for the purpose of starting them into growth to get a supply of cuttings, and induce the plants to form fine heads for early bloom. Shake out and re-pot the moment they break, and place them in a good light position where they can be well syringed and enjoy a temperature varying from 45° to 55°, according to the state of the weather. Young plants struck in the autumn should be shifted on as they require it, never allowing them to become pot-bound so as to check their growth. Nip out the points of the leading shoots to induce the buds to start regularly up the stems so as to make well-furnished symmetrical plants. Fuchsias delight in good friable loam, well enriched with the refuse from old Mushroom beds, or any cow manure that has been laid up a long time and got well decomposed. A little of either of the above well mixed in with the soil will keep it properly open, and induce them to make a rapid and vigorous growth. Pots of Lilies should at once be overhauled before they advance further into growth, or there will be much difficulty in handling them without break-

ing, either the young shoots or large fleshy roots. Remove as much of the old soil as can be done without breaking or disturbing these, using a sharp-pointed stick for the purpose. The soil above and immediately surrounding the bulbs should be all taken away and renewed. Unless there is a large increase in the number of bulbs, the same sized pots will in most cases be large enough, as they will have nearly all fresh soil to grow in, and auratum appears to do best when somewhat pinched as to pot-room. Drain well, as they take a deal of water when growing freely, and throw a handful of soot amongst the crocks to keep out worms, as these do much damage by getting between the scales of the bulbs. To obviate this, and keep the bulbs sound and clean, scatter some sharp sand over them before covering with soil. Leave 3 inches or so of the pot unfilled that the stems may have some rough lumps of soil placed round them while growing, as these emit roots just above the bulb. In potting, use good rough lumps of loam and fibry peat in about equal proportions, and do not press this in too firmly, as all large fleshy-rooted plants like moderately loose rough soil into which they can penetrate; and the quantity of water that has to be freely used then passes quickly through. Use the soil in a moderately moist state; and after potting, place them where they are not likely to dry, so as to obviate the necessity of having to give water till active growth commences.

Forcing House.

Almost anything in the way of bloom is sure to be acceptable at this early season, and there are many of the hardy early-flowering shrubs that may soon be induced to unfold their buds by introducing them to a gentle moist heat. Among the most effective of these are the early-blooming *Rhododendrons* and *Azaleas*, and a good stock of each of these should be kept up where early flowers are at all in demand, as there are few things that tend to make a house so gay, or that can be used with such good effect. The hardy *Azaleas* exhalo such a sweet perfume that a house can be scarcely overdone with them; and there is nothing more serviceable or acceptable in the cut-flower vase than a few sprigs of these. Small shapely plants of *Berberis Darwinii* and *stenophylla* are valuable for early forcing, and make a fine display when the gracefully-drooping branches are laden with their pretty bell-shaped flowers. Even the *Laurustinus*, when trained so as to form nice heads, either in the bush or standard form, are valuable at this season for decorating large conservatories, halls, &c., where they may be made to do good service, instead of risking their more choice. A very little heat will soon bring on the *Eupatoriums*; and by keeping others as cool as possible, the season of blooming may be greatly prolonged. *E. Weinmannianum*, on account of its nice smooth shiny-looking foliage and strong perfume, is the most desirable variety to grow; and, as it can be had in bloom much earlier than *riparium*, it is sure to become a favourite. These, and the *Spiraea japonica*, while growing and blooming, can scarce have too much water; and the latter may, with advantage, be stood in shallow pans, as their roots absorb a good deal of water when confined in small pots, and if allowed to become dry, the flowers soon suffer. *Solomon's Seal* (*Polygonatum*) is a valuable subject for forcing, especially for cut flowers, as the beauty of any vase is greatly enhanced by adding a few sprays of this, where its delicately-tinted green leaves and snowy white blooms are only rivalled by those of the *Lily of the Valley*. Clumps of the latter should be lifted while the weather is open, so as to be in readiness when wanted. Leaves of these are almost as valuable when forced early as the flowers themselves, as they are sure to be in request for cutting; and, if the clumps contain a fair per-centage of flowering crowns, they had better be left undisturbed, as what there are will bloom better than if torn to pieces to separate them. All plants for forcing should, if possible, be housed, or placed under cover of some kind, as, when that is done, they come slowly on, and require much less forcing. Where this cannot be done with the hardier things, such as *Rhododendrons*, *Kalmias*, &c., the pots should be plunged in leaves, and the stems of the plants protected by thrusting plenty of dry Bracken or litter amongst them. Any deciduous things, such as *Weigelas*, *Lilacs*, *Azaleas*, and such like, together with *Dielytras*, *Lilies of the Valley*, *Spiraeas*, &c., may be placed and be brought forward a stage in any closed shed by giving them a syringing occasionally. Look closely to *Hyacinths*, *Tulips*, and other bulbs in pots that are buried beneath coal ashes or other material, to see that they do not become too forward, or the leaves and embryo blooms will suffer injury. When removing them, see that they are not subjected to light too suddenly, as that is sure to cause the tender, blanched leaves to turn brown at the tips, and thus spoil the appearance of the plants. An inverted pot, placed over each bulb for a few days, or by keeping them close in a frame with a mat over for a short time, will prevent this. Introduce a few at a time into gentle heat as wanted; and if the pots can be plunged so as to keep the soil uniformly moist without having to water, the bulbs will

be all the better for it. A few greenhouse *Azaleas* may now be introduced into gentle heat, selecting any well-known early bloomers for that purpose. Give time, maintain plenty of atmospheric moisture, and force slowly. Take advantage of every gleam of sunshine so as to save fires as much as possible. It is a too common practice to give air too freely when the sun makes its appearance, instead of anticipating its presence by slackening or wholly stopping the fires, and allowing the sun to do their work, which it will in a more satisfactory way. The air of warm houses is being constantly changed through the laps of the glass and other crovices, and therefore but little provision need be made for doing so in any other way at this early season, as it is only a waste, and brings in a lot of cold air that chills the tender leaves of plants subjected to early forcing. As flowers of forced plants open, keep them well up to the light, so as to give substance and render them more enduring.

Hardy and Half-hardy Fernery.

No place is complete without an appendage of this kind, as here many shade and moisture-loving plants can be accommodated and find a suitable home, that could not be successfully treated elsewhere. Where plants of doubtful hardiness are being tried, they should have ample protection afforded them by placing a sufficient quantity of *Coccol fibre*, old tan, sawdust, or perhaps best of all, some fresh dry leaves round them. Over these, some Bracken should be laid to prevent them from blowing away and exposing the plant. The utmost vigilance must be exercised to see that none of the protection afforded becomes displaced by birds in quest of food, or that the plants do not become disturbed or destroyed by rats or mice, that often make sad havoc among them in sharp weather when covered up. Such plants as *Palms*, *Draconea australis*, *Aspidistras*, or others of that class, associate well amongst with only slight protection, such as that mentioned above. In no case, however, should things of doubtful hardiness be experimented on or turned out till the spring of the year, so that they may make and harden their growth in the position allotted them. When the time arrives I hope to touch on a few Ferns and other plants that may be ventured out with tolerable safety. Except for such hardy strong-growing Ferns as *Struthiopteris*, *Lastreas*, *Oncoleas*, *Osmundas*, and others, planting had better be deferred for some time longer, and even with these nothing is gained, as they make but little, if any, root, till they begin to grow. — J. SHEPPARD, *Woolverstone Park*.

Indoor Fruit Department.

Vines.—The past season has not been at all favourable for the ripening of late Grapes. In Durham, the rainfall has been above the average, and outside borders have had too much wet. Where such has been the case, and the borders have only been protected from frost by means of manure, let the latter, if in quantity, be wholly removed; but if only a thin layer, let it be shaken up to dry. Examine also the main drain in front of the border, in order to see that it is in good working order; pinch out all laterals in early houses, so as to avoid overcrowding. Where the fruit is thin and swelling, keep up a brisk heat by day, admitting air cautiously; indeed, in old or wide-glassed houses, little will be required. In houses not so forward, but where young shoots are pushing freely, advance the night temperature to 65°, leaving a little front air when the weather is favourable. Disbud all to one shoot from an eye, leaving the strongest, which invariably furnishes the finest bunches; if very strong, be careful in tying them down, as they will scarcely bear their own weight. Stop them at two or three leaves beyond the fruit. Late houses in which only a few bunches remain should be pruned, cutting and placing the clusters left in bottles of water, so as to allow the house to be cleaned and put in readiness for starting afresh. Where it is intended to bud or graft an old Vine, let it be done near the bottom, and leave the side-shoot, on which the graft or bud is to be put its full length, inserting the eye near its extremity, where it will start quicker than when placed close to the old Vine. Thus managed, the rafter should be refurnished in a season, if all goes well.

Pines.—In houses in which the latter fruit-bearing plants still remain, they had better be got together, or taken to a smaller house where proper attention can be given them. If moved to another house, they must be re-plunged immediately, for, if allowed to stand without bottom-heat at this season, the fruit will cease to swell, and a premature finish will be the result. Have the house for succession plants thoroughly cleaned, if not painted, the bottom-heat looked to, and fresh tan supplied, if necessary, ready to receive the plants from which next winter's fruits are to be cut. Suckers, rooted in 6 and 8-in. pots last September, and subjected to a bottom-heat of 75° or 80° through the winter, will have well filled their pots with roots, and should now be potted into 11-in. pots, with a view to growing

them on briskly for four months. When rested after that for a month or six weeks, they will readily show fruit, and, as a rule, produce the best winter crops, Queens excepted. See that plants in early houses do not suffer from drought; but, if the soil be moist throughout, it is not advisable to use much water until they show fruit. Admit air on all favourable occasions; but shut up early in the afternoon, so as to take advantage of sun-heat. Sprinkle all available surfaces; but avoid the use of the syringe amongst the plants at this dull season. Maintain a night temperature of from 65° to 70°, with a corresponding rise of 10° by day.—J. HUNTER.

Kitchen Garden.

A systematic rotation of crops should, if possible, be adopted in every kitchen garden, especially where manure is scarce, in order that the first or direct supply of it may be given to such vegetables as require the richest food; for this reason, notes as to the cropping of the various quarters each season should be kept on a plan of the garden. The following rotation has answered well on our light soil here, viz., on south borders and in other warm situations. First crop, early Potatoes; second, same season, French Beans; afterwards, Lettuces to stand the winter. Second season, early spring-sown Cauliflower, and then deeply worked and manured for the November sowing of Peas. The open quarters are cropped as follows; first, Potatoes, Broccoli, Celery, Peas, winter Spinach, Carrots, Onions, and Cabbage. Another rotation is Potatoes, Brussels Sprouts, Celery, Parsnips, Scarlet, French, and Broad Beans, Turnips, Savoy, and Broccoli. Occasionally it may be advisable to vary these rotations, but as a rule they may be adopted with safety. Parsnips and Onions require a long season, and the sooner they are sown now, the better, *i.e.*, if the ground be in a fit state for the reception of the seed. Parsnips enjoy deep tith, and if manure be added, it should be placed at the bottom of the trench; sow the hollow-crowned variety in drills 15 inches apart, and cover to the depth of 1 inch. The ground for Onions should be somewhat firm, and if not so naturally, tread or roll it, previous to which apply a surface-dressing of either soot, lime, or wood-ashes, the three mixed together being best; sow the seed also in drills half-an-inch deep and 12 inches asunder, cover by hand, and again tread or roll the ground, in order to ensure the seed being made firm in the soil. The best varieties are Reading, or White Spanish, Blood Red, and James' Keeping. A good breadth of Potatoes may now be planted, selecting the sets from such as have been laid thinly on shelves, or in shallow boxes of soil, to sprout; draw drills for them at least 9 inches deep and 2 feet apart, and set the Potatoes firmly 1 foot from each other in the row. Care should be taken not to break off or injure the sprouts, and not more than two should be left on each set. The best early varieties are the Old Ashleaf, Veitch's Improved Ashleaf, Early Market, and Early American Rose. Jerusalem Artichokes may also now be planted, and as they make a large amount of top growth and shade all the crops near them, it is advisable to grow them in some out-of-the-way corner. Any situation or aspect will suit them, provided the soil be moderately rich. The rows should be at least a yard apart, and the sets 18 inches asunder; they will then grow up strong enough to resist any ordinary gale of wind. Rhubarb plantations should now be manured and dug, and, where necessary, new ones made; for, if left on the same ground too long, it deteriorates both in quality and quantity. The old stools should be split up into single crowns and planted a yard apart, and if not pulled during the summer these will make the finest roots for forcing next winter. For the latter purpose Johnston's St. Martin is the best; and, for out-door growth, Myrati's Victoria. Should the earliest-sown Peas be likely to prove a failure, which often happens, lose no time in sowing again. A week, perhaps, may be gained by sowing in heat on strips of turf and planting them out when a couple of inches high. This mode entails a good deal of labour for very little profit; but, where labour is plentiful, I recommend it to be done as follows:—Cut turfs into convenient lengths, 2 inches thick and 3 or 4 wide, turn the Grass side downwards, and cut a small furrow along the centre; in this sow the Peas and cover them well through the soil, and then move them to a cold pit or frame; plant them out as soon as the roots protrude through the turf, protecting them well with ever-green branches from cutting winds and sharp frosts. Broad Beans may be sown, and treated in a similar manner. Give abundance of air to Lettuce, Endive, and Cauliflower plants in frame, sow a boxful of Early London Cauliflower in heat, to succeed the plants now in frames. Lettuce, Brussels Sprouts, and a first sowing of Celery should also be made forthwith in heat. Keep up successive supplies of Asparagus by making a fresh bed fortnightly. A crop of Radishes may be had by thinly sowing over the Asparagus; and Lettuce and Cauliflower plants can be raised in the same way.—W. WILDSMITH, *Heckfield*.

PRESERVATION OF COLOURED PLATES.

AS, doubtless, our subscribers desire to preserve THE GARDEN coloured plates in as good condition as possible, we venture to offer the following directions for that purpose, furnished by one of our artists, who has paid much attention to the subject, which is one of some importance to all who possess water-coloured drawings or chromo prints, and who wish to preserve them. Exposure to sunlight and damp are the two great sources of decay in coloured plates; if they be placed in the full glare of the sun or in strong reflected light, they will fade in time, the paper become discoloured, and all that gave pleasure to the eye will disappear. This, too, will take place, even when they are "framed and glazed," certain red colours fading first. In order to obviate the evil, all prints should be kept in a drawer or portfolio, or more conveniently in their proper place between the leaves of THE GARDEN, until they can be bound into a volume, taking care to avoid the second source of decay, viz., damp, which is quite as destructive and more insidious than sunlight. It makes its presence known by dulling the brilliancy of the colours and spotting or discolouring the paper, especially at the edges; dark spots become visible in the light parts, and light spots in the dark parts. This evil is much increased by mounting the prints for framing, &c., with bad paste. When the numbers of THE GARDEN are delivered to subscribers, they are, of necessity in a slightly damp condition; therefore the plates should be removed, the body of the work itself should be dried by the fire, or in any convenient manner, and the pictures should be returned to their proper places; do not, however, dry the plates themselves by the fire. When the numbers are not in use, place them in a drawer, or altogether in any dry place at hand, where they will be easy of access for reference. When the volume is returned by the binder, it is usually in a damp state, and if allowed to continue in that condition, fading of the colours will follow. It is well, therefore, to open it, and expose it in several parts to gentle heat, or to place slightly warm blotting paper between the leaves in several places; then close the volume, and place others on it, or use any other means for drying the leaves that may suggest themselves, but do not place the volume near a fire or in the direct rays of the sun. If it be in use, turning the leaves over is the best possible mode of drying them. In framing the plates of THE GARDEN, let the glass be gummed or pasted to the frame, place them in "sunk mounts," hang them out of strong light, and protect them from damp by placing, in addition to the usual precautions, patent painted cloth at the back. Applying varnish or gelatine to the face of the plates is useless. By adopting these precautions water-colour pictures may be preserved from injury, but, besides sunlight and damp, other evils, though of a smaller kind, present themselves. When THE GARDEN is forwarded by post, the coloured plate often gets creased and crumpled. This may be remedied by placing it between one or two sheets of clean damp paper for a short time, and pressing it flat under a weight laid on some protection between it and the print; remove the plate when it has become damp or limp, place it upon two or three sheets of very dry clean paper, face downwards, and put over it two or three other sheets of similar paper, and over all a large book, and more books on that to act as weights. In this way it will become quite flat in two or three hours, or it may be removed from the damp papers and placed at once between the leaves of a large book under a weight. If the edges be slightly torn or frayed, use the scissors very sparingly, or it will not bind up well. H. HYDE.

Dangerous Fungi.—The Agaricus personatus, one of our common so-called edible fungi, formerly sold in Covent Garden Market, and even now exposed for sale in the market of Nottingham under the name of "Blue Hats," has, according to Mr. Berkeley, been supposed to be occasionally dangerous. Mr. W. G. Smith has recently had sent him from Yorkshire (Hovingham) some typical specimens of this fungus, with the information that the "keeper" had gathered a dish of it and cooked it for the table, with the result that soon after taking it the whole party—himself, family, and friends—were seized with vomiting and pain in the pit of the stomach. From this it would seem that the fungus is really at times dangerous, and should be eaten with caution. Mr. Berkeley has since confirmed this. He states that some years ago the late Professor Henslow sent a quantity of Mushrooms, consisting entirely of this species, which formed part of a basketful of which some persons in Cambridge had partaken, and had died in consequence. As A. personatus has not only the reputation of being wholesome, but is sold in some of our markets, it was supposed that some deleterious species had been mixed with the others, and had proved fatal. It would seem, however, he says, from this additional information, that he was wrong. It is, however, pretty certain that species which are in general wholesome occasionally contain such a portion of their peculiar alkaloid as to be dangerous.—"Florist."

THE FRUIT GARDEN.

CLEARING VINES OF MEALY BUG.

WHEN Vines are leafless and at rest is the best time for this kind of work. In the first place, every crack or crevice in the walls must be stopped, either with mortar or cement—the latter is best; then they should be washed over with lime-wash, made rather thick. All painted surfaces, such as rafters, sash-bars, sills, doors, &c. should also be well scrubbed with a brush, using a strong solution of soft soap or Gishurst Compound for the purpose. About 8 ounces, dissolved in a gallon of water, and used when warm, will destroy any insect with which the solution comes in contact. The Vines should then have all loose bark removed, and be washed in the same way, avoiding doing any injury to the buds. If the lights can be taken off and the house thoroughly painted, all the better, as the insects often hide themselves in cracks between the lights and rafters, where they may be overlooked or where, at least, it is difficult to reach them. Where this cannot be done, or where the roof is a fixture, every crack should either be filled up with putty, or Gishurst Compound Paste should be rubbed into every place where the brush and solution could not penetrate. The Vines should then be painted with the following mixture:—Dissolve 1 pound of Gishurst Compound in 2 gallons of water; then add 2 pounds of sulphur, and sufficient lime and soot to bring the mixture to the consistency of thin paint, making the colour light or dark by adding lime or soot as desired. When cleaning and painting the Vines, the earth for some distance round the stems should be removed down to the roots, in order to destroy any insects that may have buried themselves round the stem underground. It will be advisable also to remove 6 in. of the soil from the inside borders, and to substitute good fresh loam. This I should do even if a few roots had to be sacrificed. If when the Vines are started a hot-bed of leaves and dung could be made on the inside borders and occasionally turned over, it would have a beneficial influence upon the Vines, and at the same time tend to keep down insects. Even after all this has been done, and well done too, it is just possible that eggs or larvæ may have been left somewhere; in fact, when once established, it is a rare occurrence for one dressing to destroy every insect, but by care and watchfulness during the following spring they may be entirely got rid of. Even up to the time when the Grapes are fit for thinning, a daily examination should be made from the ground up to the top of the house. About 11 o'clock in the morning, the insects, if any be present, will generally be found on the main-stems, within a few feet of the ground, in which a few eggs or larvæ may have been left. A few minutes each day devoted to looking over a large house are sufficient; and, when once a Vinery is cleared of this pest, particular care should be taken not again to allow it a footing, as it is impossible for Vines or Peaches to be infested with it, without the appearance of the fruit being spoiled. It is useless, however, to attempt remedial measures, unless plants suspected to be infested with mealy bug can be kept out of the houses devoted to fruit culture. H.

Gros Colman Grape.—There has been a good deal of inquiry lately concerning the keeping and other qualities of this Grape. I saw it lately at Drumlanrig Castle in the most perfect condition—superb examples both in bunch and berry; the flavour, too, was excellent. Mr. Thomson considers it one of the very best late Grapes we have. The Vines at Drumlanrig are marvels of vigour. Though only making a start—all having been re-planted since the Phylloxera attacked the former ones—they were heavily cropped, nearly 6 ft. of young wood having been left at pruning time; and we believe some of the bunches sent to dessert from supernumeraries weighed 12 lbs. The Gros Colman seemed to run from 3 to 5 lbs., but some of the finest bunches had been sent away, before I saw them, for a special occasion.—S. W.

Charles Downing on the Yellow and Green Newtown Pippin Apples.—I can only say in my young days—some fifty or sixty years ago—these Apples were always considered as two distinct kinds. As to their origin and history none has been given that I am aware of, except that the Newtown Pippin is said to have originated in Newtown, Long Island, but whether a chance seedling, or raised

by some person, is not stated. Cox, in his work on Fruits, states that one is a variety (seedling) of the other. The Fall Pippin, Rhode Island Greening, Tompkins County King, and many other kinds, have no origin assigned them, but does this prove that there are no such varieties? The yellow Newtown Pippin is the Albenmarle Pippin of Virginia. It is said that the bark and growth of the two kinds are alike, which is true when young, but with age, the yellow variety makes a much larger and more spreading tree than the green kinds. The fruit of the yellow variety is yellow soon after being gathered, while the green is always green until spring, when it changes to a greenish-yellow; the yellow has a shade of brownish-red, and sometimes spots or blotches of red on the sunny side; the green seldom or never has any red on it; the form of the yellow kind is oblate, oblique, slightly conical, while the green sort is oblate, slightly conical, and in well-grown specimens regular, but in smaller ones more or less angular; the flesh of the yellow kind is quite firm, breaking, juicy, rich and aromatic, while that of the green sort is crisp, or brittle, tender, very juicy, rich and aromatic. As to the two varieties being found on the same tree, it reminds me of a remark made by a celebrated pomologist, viz, that he could select twelve Apples from a Rhode Island Greening, which any fruit committee would decide to be twelve different kinds, so you may select both yellow and green Newtown Pippins from the same tree, but the general crop of the yellow variety will be yellow, and so of the green. I doubt if the matter will ever be settled to the satisfaction of all.

Wire Strainers.—The accompanying illustration represents a neat and useful mode of straining galvanised wires on walls by means of screws and nuts, the fittings connected with which can be readily fixed by any ordinary workman. It is used by Messrs. Reynolds and Co., of Soho Square. The most convenient distances for fixing wires on brick walls are found to be 6, 9, or 12 in. apart.

Mode of Straining Wires on Walls.

The terminal holdfasts are driven into a cross joint at the end of a brick, and where 6 or 12 in. spaces are adopted, they form a vertical line from top to bottom of the wall; but if the space chosen be 9 in., the holdfasts must be placed half a brick in or out of a vertical line. The eyes through which the wires run should be driven into cross joints about 10 ft. apart. The Radaisseur or strainer is attached to one of the terminal holdfasts by a small bolt and nut supplied with it. Where straining screws of this kind are adopted, the best plan is to use one at each terminal holdfast.—H. S.

Frost in Valleys.—More than thirty years ago we urged the importance of not planting tender fruit trees, such as the Peach, at the bottom of valleys, where the cold air settles, and where the warmth in summer and autumn promotes a more succulent and tender growth than elsewhere. But it appears that even now some are slow to believe it. It appears that some have attributed the greater cold indicated in valleys to the variation in thermometers. Ten thermometers were accordingly procured. On low ground they went down to 9° below zero; on being removed only 11 feet higher to a small ridge, all rose to 8°. Higher points showed greater differences. We have known Peach buds to be wholly destroyed at the bottom of a hollow; while 60 ft. higher, and out of the lake of cold air, the trees bloomed profusely.—“The Cultivator.”

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Autumn-Fruiting Raspberries.—I am desirous of purchasing some autumn-fruiting Raspberries, and row write in the hope that amongst your numerous readers I may hear of some one able to supply me with them. I have tried several nurseries, but without success.—T. J. CARTER, Rackham, The Grove, Catton, near Norwich.

Cox's Orange Pippin in Devon.—We have recently seen some beautiful specimens of this Apple, grown by Mr. Garland, of Kilmington. Some of them measure 10 in. round. These fine fruit, however, have now lost their high flavour, and, probably could not, in keeping, compete with smaller fruit of the same kind from midland localities. Of these a few specimens are yet obtainable in the market.

ORCHARDS AND THEIR CULTURE.

By an orchard I mean an enclosure entirely devoted to the culture of the larger fruits, such as the Apple, Plum, Pear, Cherry, and occasionally the Medlar, Mulberry, and Quince. The three latter, however, are grown more for ornament and curiosity than for use, and, where they are required, one or two of each sort will be found sufficient for even a large establishment. The Cherry is rarely a profitable orchard crop in woodland districts, on account of the prevalence of small birds, which destroy the produce; but a judicious selection of the hardier Plums may be rendered sources of remuneration. In most gardens of importance, many of our best Pears are either cultivated as wall trees or as pyramids, and undergo a regular system of summer and winter pruning; but many of the finest-flavoured Pears are found to succeed quite as well in the form of standards or ordinary orchard trees. Selecting trees for an orchard is a matter that requires careful consideration, and the site should be such as possesses a suitable soil and climate. Where the fruit is grown for market (and supposing we are planting 500 Apples, instead of planting 100 sorts, all of different growth and coming in at different periods) I would plant 50 or 100 of a sort well known to succeed in that particular locality. When they are grown for private consumption the selection should be made with a view of prolonging the season as much as possible. Some of those Apples found to succeed in the northern counties and north of the Tweed do not succeed so well south of the Trent, and the same is the case with regard to Pears. Some that succeed as standards, and are considered valuable for their richness of flavour in the north, are comparatively useless in the south, but our southern neighbours have a corresponding advantage, for in the north many of the valuable fruits that are so popular in the south do not come to perfection. Most of our Plums will succeed as standards in ordinary localities and situations; in fact, where the common Gooseberry will thrive and bear fruit, there will the Plum prosper, and an orchard will not be complete without several Cherries of the Mayduke, Bigarreau, and Morello section, if there be any chance of their escaping the ravages of the birds. The first consideration in the formation of an orchard is to properly prepare the ground. I would here advise the inexperienced planter to provide in the first place against excess of moisture, for no good fruit culture can be carried out where stagnation exists. I must not here confound mere retentiveness in a surface-soil with a wet and sour subsoil. The draining of the one, and the mere improvement of the mechanical texture of the other, are, of course, two operations essentially different. When drains are necessary, they should seldom be less than $3\frac{1}{2}$ or 4 ft. deep, with provision for their proper discharge. Where there is the choice of situation, the site should be a gentle slope to the south-west; and the soil, when one of that character can be secured, should be a deep loam, rather tenacious, resting on a dry subsoil—if strong, all the better. We cannot always command situations suited to individual wants, but unfavourable ones may be somewhat improved. Locality has much to do with the success of the fruit crop, and over this we have little or no control. It may be asked what has made Hereford and Devon such fruit-growing districts? It cannot be soil alone, it cannot be in the planting or after-culture, but it must be atmospheric influence. The fact of the matter is that whatever efforts may have been made in other counties—and doubtless many have been made both by the present and past generations—yet these two counties, Hereford and Devon, still stand unrivalled for fruits. With regard to the improvement of any given situation, we all know that thorough drainage in wet localities will accomplish wonders. Whatever be the character of the soil, it will be essential to trench it deeply, and to work into it at the same time a quantity of strong farm-yard manure. In planting, avoid that higgledy-piggledy, off-hand style too often met with in orchards attached to country houses. If an orchard be worth planting at all it should be done well, especially at the commencement. The trees should be planted in rows, abutting north-east and south-west, or north and south, so that the sun may shine between the rows during the warmest portion of the day. Unless it was desirable to keep the Pears as pyramids, and let them undergo a regular system of summer

and winter pruning, we should plant all standards on straight stems, 5 or 6 ft. high. The distance to plant them apart should be 10 ft. row from row, and 10 ft. asunder in the rows. In the course of twelve or fifteen years, if the soil be good and the trees have prospered, they will almost touch each other, when every alternate row may be removed. If it be in contemplation to form a fresh orchard, every tree that has to be removed should be properly root-pruned during the winter previous to removal, and then they will move with perfect safety, and soon come into bearing condition in their new quarters. In three or four years more every alternate tree may be removed, leaving the permanent trees 20 feet from each other every way. By this time they should be well-developed trees, with the branches spreading in all directions, and nearly occupying all the ground. Where the land is at all inclined to be wet, the trees should be planted on slightly-raised mounds; but if the drainage be made good, or the soil be of a light character, this will be unnecessary. At the time of planting it would be of great benefit to give each tree two barrow-loads of fresh soil, say the parings from the sides of lanes, or anything that is fresh and full of fibre. This is much better than placing rotten manure in contact with the roots, for it encourages the emission of young fibres, and produces a better quality of wood. For two or three years after planting half of the space between each row may be cropped with Potatoes, dwarf Kidney Beans, or Spinach, but it must be a crop that does not root deeply. After that the whole of the ground should be left uncropped. In the course of a few years the ground may be sown with grass seeds, but the trees should have a good start at first. For a year or two they will require mulching with rotten manure, which should be occasionally renewed. During the first year after planting give the trees plenty of water, and pour it over the mulching material. Respecting the time for planting fruit trees there is but one opinion. The best time in the whole year for planting all trees that shed their leaves in winter, whether fruit-bearing or otherwise, is from the end of October to the end of November. They may, in fact, be planted with success from October to the beginning of March, but they are best planted as soon after the leaves change colour as possible. The chief reason why planting should be performed as early after the leaves turn yellow as possible is that the earth is then warm. Fifteen inches below the surface it will be found to be 8° or 10° warmer in October than it is in January or February, so that the mutilated roots are, comparatively speaking, placed in a gentle bottom-heat, which rapidly promotes the growth of fresh fibres before the earth gets cooled down by frost. By early autumn-planting the trees are, to a great extent, established before the dry winds of spring set in, and are capable of breaking into vegetation with greater vigour than those planted later in the season. When planting, choose a dry time for the purpose, if possible. Care must be taken to spread the roots out in all directions, and in as straight lines as possible. In neighbourhoods where rabbits and hares abound they are almost sure to bark the trees in hard weather. To prevent this they are sometimes painted with various compositions, but whatever is applied in a liquid state must be renewed once or twice during the winter, or it will lose its effect. The best and most effectual remedy, however, is to wrap a piece of galvanised wire netting loosely round the stem of each tree to a height of 3 ft., a plan which will effectually prevent injury from ground game, and the wire will last many years.

Q. R.

THE ROOF TREE AT KNEBWORTH.

“Read the Rede of this Old Roof Tree,
Here be trust fast. Opinion Free,
Knightly Right Hand. Christian knee,
Worth in all. Wit in some.
Laughter open. Slander dumb.
Hearth where rooted friendships grow,
Safe as altar even to foe.
And the sparks that upwards go,
When the hearth-flame dies below,
If thy sap in them may be
Fear no winter, Old Roof Tree.”

—LORD LYTON.

THE INDOOR GARDEN.

CUTTING BACK CAMELLIAS.

CAMELLIAS which have been allowed to grow for many years without pruning or training, often require to be cut back freely. Plants needing this treatment are seldom in a robust state of health, and the few flowers which they produce not only lack size and fullness, but generally decay and drop prematurely, an evil which does not apply to old plants only, but also to comparatively young ones. When such plants are furnished with plenty of strong active roots, their long leafless branches should be cut back to about half their length as soon as they have done blooming; but it must be borne in mind that to cut plants down when the roots have not power to produce growth quickly is productive of more harm than good. In the case of tall plants, the first thing needful is to have plenty of roots, and, where these do not exist, re-potting should take place without disturbing the top, until the roots have been got into a healthy growing state. Where the roots are good, even old plants may be cut well in; but in general it is safest to cut back part of the branches one year and the remainder the following season. After Camellias have been cut down they should be placed in a temperature of 60°, in order to induce them to start again into growth. The atmosphere should be kept moist, and the tops of the plants should be syringed at least twice daily. When the young shoots have grown 2 or 3 inches in length, the plants may be removed into a light airy house where the air is not saturated with moisture; but while breaking it is of much importance to have the wood constantly moist; and in cases in which it is very old and hard, a little Sphagnum or other kind of Moss thinly spread out and tied round the branches facilitates the production of fresh buds. Plants which fail to perfect buds or blooms should be cut down at once, and placed under growing conditions such as those just described; and if all goes on well the young wood formed now will bear blooms about this time next year or probably earlier. Camellias which are planted out are not in general so leggy as those in pots; but even these, if large and bare, may be cut down prior to being started into growth, and if they can have a little more warmth than is given to conservatory inmates generally for a month or two, all the better. The growths will be found to need tender treatment for a time, and to be shaded from strong sunshine, but when hardened off a little the more light they get the better. Frequent syringings during the hot summer weather serve to keep down red spider and other insects.

J. MUR.

LEAN-TO GREENHOUSES, HEATED BY FLUES.

My small suburban garden has not the open space necessary for a span-roofed greenhouse, without sacrificing many well-established fruit trees and shrubs, while there is ample room in a sunny corner for a lean-to house; but the account given of such structures in your last number (see p. 60) makes me hesitate about erecting one for general use, although the back wall for it, facing W.S.W., is already built, and a flue inserted about 8 ft. from the north end of the wall. Do you consider the circumstances justify the erection of a lean-to? If so, I should be glad of any suggestions tending to mitigate the inherent defects of this form of house and the liability of the flue to crack. Would it be better to build right in the corner and have one end of the house brick, or build more in the middle, so as to have glass at both ends?—S. [If "S." has no place to which he can remove his fruit trees and shrubs that occupy the site which he would devote to his span-roofed greenhouse, and he values them more than what he intends growing in his proposed house, there is then no resource except putting up a lean-to house. Could not a span-roofed house be built with one end abutting on the wall against which he proposes to erect the lean-to house? The importance of securing the greatest possible amount of light for both plants and fruits grown under glass cannot be over-rated, and therefore unless the existing wall be a divisional one that cannot be touched, might it not be lowered so as to form one side of the span-roofed house? If neither of these suggestions can be carried out, "S." need not, however, despair of succeeding with a lean-to, although flowering-plants grown in this description of house are seldom or never so satisfactory as in a span-roofed one. By all means keep as far away as possible from the corner mentioned, and if possible have glass at both ends. As to flues, instead of being built in

the ordinary way with the bricks on edge, you should have them laid flat; in this way the flue is not quite so soon warm, but it retains the heat absorbed by it correspondingly longer, and is much less likely to leak; let it be at least 9 in. wide inside and 1 ft. or more deep, according to the width of the house; the larger the flue the more heat it will give off, diminishing the necessity for making it over-hot, and consequently reducing the quantity of fuel required. See that good mortar is used in its construction, and that the bricks are well laid; bed the covers in hair mortar, and lay a strip of hoop iron, 1 in. wide, across under each joint of the covers. This will keep the mortar from dropping out, and prevent the escape of smoke. Build the furnace altogether outside the house, and make it large enough to hold a good body of fuel, so as to last for eight or ten hours without attention; for a small house, 16 in. deep by 12 in. wide and 20 in. in length will not be too large. Sink it low enough, so that the flue may rise a little as it enters the house, and continue to do so all the way round until it enters the chimney-shaft. Do not let the flue dip at any point; if it cross a path or doorway, let it be got over by means of steps. A flue with a dip rarely draws well. The internal arrangement of stages will depend upon the size and description of plants to be grown on them.

T. BAINES.

Myosotis dissitiflora Indoors.—This beautiful Forget-me-not promises to bloom early this year, as its minute buds are already becoming apparent. Should the weather remain open, I anticipate that we shall have it in good bloom by the end of February. For pot-culture it is best to lift and pot up the plants just before the buds begin to expand, as if kept long under glass before blooming, they are subject to two evils—damping-off and greenfly. Plants lifted and placed in an airy house push rapidly into flower, and remain objects of beauty for several weeks. I am surprised that this pretty flower is not largely grown for the London market, and especially for window-boxes. A carpet of it for boxes of white or red *Hyacinthus* or *Tulips* would greatly enhance their beauty.—A.D.

Culture of Ixoras.—Judging by the description given by "J. P." (see p. 66) of the way in which *Ixoras* grow in the open air at Bangalore, it might be supposed by those who have not had practical experience in their cultivation under glass, that the amount of humidity in both soil and atmosphere which I recommend is unnecessary. There are, however, some conditions under which a plant may exist, even in its native habitat, that would often be found anything but advisable to imitate in artificial cultivation, under which these and similar plants must be considered to be in this country. When the atmosphere of the house in which they are grown is kept dry, the flowers and leaves are always small and puny.—T. BAINES.

Orchids in Bloom at the Victoria Nursery.—The following Orchids are now in flower here, viz:—*Cattleya Trianae* striata and other varieties, *C. Chocoensis*, *C. Warewiczii* delicata and aurantiaca, and *C. Russelliana*; *Calogyne cristata*; *Calanthe Turneri*, and the white and yellow-eyed varieties of *vestita*, and *C. Veitchii*; *Cypripedium Bullenii*, *C. barbatum*, *C. Harrisianum*, *C. Dayanum*, and *C. villosum*; *Colax jugosus*; *Dendrobium nobile*, *D. crassinode*, and *D. japonicum*; *Helcia sanguinolenta*; *Lælia albida*; *Lycaste Skinneri*, *L. delicatissima*, *L. rosea*, and *L. grandiflora*; *Miltonia cuneata*; *Masdevallia ignea*, *M. polysticha*, and *M. Lindeni*; *Odontoglossum blandum*, *O. cariniferum*, *O. membranaceum*, and *O. stellatum*.—B. S. WILLIAMS.

Hepaticas in Pots.—For the next few weeks, no one who has to furnish a supply of cut flowers, or who wishes to have pretty flowers for house or window decoration, should be without a few strong plants of diverse kinds of Hepatica in bloom. Among small hardy early spring flowers, few make up so prettily for button-holes, or for small bouquets; and along with them may be used a few blooms of Queen Victoria Violets to give perfume. Strong established plants, in pots, will flower earlier than similar plants in the open border; and, at a time when all kinds of flowers are scarce, it is well to have some under glass, as they are thus kept from rain and frost, and preserve their freshness and beauty for a long time. Hepaticas are impatient of frequent removal, and when once established in 6-in. or 7-in. pots, they should be occasionally top-dressed; but not too often re-potted; the greatest check, however, is given when a plant has so increased in size as to render division necessary, but if such plants be not required to make stock for sale, it is best to divide sparingly, say into three or four divisions, and these if re-potted at once soon become re-established. Small plants should be potted into 60-sized pots, and in these they may remain the first year, plunged in ashes in a shady situation for the summer. The next year they may be shifted into pots a size larger, and so on until a size sufficiently large for them is reached. If kept cool, free from weeds and worms, and liberally supplied with water, so that plenty

of foliage is formed, a fine head of bloom will be the result. The most suitable sorts are the Single White, Blue and Red, the Double Red and Blue, and the well-known pale blue Angulosa.—A. D.

Thunbergia, Harrissii.—This, though seldom seen in cultivation, is nevertheless, when well grown, one of our best flowering evergreen stone climbers. It is by no means difficult to manage, and when in bloom at this time of the year, besides being ornamental in the house in which it is grown, it assists in filling the cut-flower basket. Its greatest enemy is red spider, but with proper drainage and liberal supplies of water when growing, both at the root and in the shape of daily syringings, this can be easily kept in check. Like most other climbers, it grows best when planted out in a well-drained border, consisting of rough fibry loam, leaf-mould, and a little sand and charcoal, all well mixed together. The back wall of our plant-stove is faced with soil kept up by wire net-work, and covered with *Lycopodium denticulatum*, and on the top, within 6 inches of the glass, we planted the *Thunbergia* and several other creepers, and trained them to wires that run across the house. Thus treated they have grown well, and several of them, such as *Ipomoea Horsfallii*, *Euphorbia Jacquiniflora*, are now in flower. The creeping Fern, *Lygodium scandens*, runs up the wires, and when carefully trained, we can easily cut from it long pieces which, drooping gracefully from *épergnes*, have a pretty appearance.—A. H., *Thoresby Park*.

Culture for Transport.—M. Rivière, in Algeria, is growing Palms and other tropical plants in very small pots, to secure economy in transport. The pots are not more than a few inches—3 to 5—across, and, in some cases, the diameter of the base of the stem of the plant is nearly as great as that of the pot. The pots are plunged in the open ground, which is constantly moistened by small rivulets. The roots enter the earth through the bases of the pots, but these are removed from time to time, to prevent their rooting too strongly in it. The method reminds us of a similar one pursued in the Mauritius, where young Palms and like plants are raised in pots formed of pieces of Bamboo stem. In these, we have received consignments of valuable plants from the Mauritius, with scarcely any loss.

Want of Chlorophyl in Seedlings from Variegated Plants.—M. Lemoine states that "out of some 3,000 seedlings of *Phormium Colensoi*, all of which came up yellow, only about 100 remained alive, and that he expects these will soon wither away and die." On the other hand, M. Rongier says, that although all his seedlings of this Flax are also yellow, yet some of them seem healthy and look as if they would live; but, as far as his experience hitherto goes, they have little or no chance of doing so. I may add that similar results have occurred in the case of seedlings from the variegated *Fatsia japonica* (more commonly known as *Aralia Sieboldii*), the *Acer Negundo fraxinifolium variegatum*, the *Mesembryanthemum cordifolium variegatum*, the beautifully variegated bedding *Tropaeolum* named *Minnie Warren*, and several varieties of variegated-leaved Holly. The seedlings of all these come up either creamy-yellow or white, and perish after attaining their second or third leaf beyond the seed-leaf. Is it not therefore surprising that the seed should germinate at all?—W. E. GUMBERTON, *Belgrove, Queens-town*.

Flowering Bougainvillea spectabilis.—Mr. Spelman asks (see p. 83) :—"How can I induce this *Bougainvillea* to produce its mauve-coloured bracts?" This has puzzled many cultivators of this plant. In a warm conservatory here, I planted it out in a border, and it grew vigorously every year, but never flowered. I had it at last carefully lifted, with as many roots as possible, and re-planted in a narrow border, with nearly a foot of broken brick-bats for drainage. It grew very weakly in the summer, but was assisted with some weak manure water until the autumn, when water was withheld at the roots all through the winter months, until nearly all its leaves dropped off. In March, its roots were well watered again, and its branches frequently syringed, and in June I was rewarded by seeing wreaths of its mauve-coloured bracts on every young shoot. It has flowered well every year since, under the same treatment, until last year, when it only flowered sparsely. *B. spectabilis* does not flower freely when grown in pots, although *B. glabra* will.—WILLIAM TILBERRY, *Welbeck*.

Eranthemum pulchellum in a dwarf state.—I find this old-fashioned stove plant to be very useful in a dwarf state. To secure it in this condition, we strike the flowering points from old plants, in the way we propagate Poinsettias, rather late in the summer, and they furnish pretty heads of bloom when not more than 6 in. in height.—J. GROOM.

Grafting Periwinkles on the Oleander.—According to the "Revue Horticole," M. Landotte, an artist at La Mucette, conceived the idea of grafting different varieties of Periwinkle on the Oleander, and successfully accomplished it. This is, however, not so surprising as it appears at first, for both genera belong to the Apocynæ etc. It is even probable that the pretty *Vinea rosea* from Madagascar would succeed on the Oleander.

THE KITCHEN GARDEN.

MR. CARRUTHERS' REPORT ON THE POTATO DISEASE.

The Royal Agricultural Society deserve thanks for the practical steps they have taken to elucidate the mystery of the Potato disease, but, as many predicted, the experiments now recorded by Mr. Carruthers confirm nothing so certainly as the opinion entertained by all Potato-growers from the beginning, that the disease is caused by excessive wet. In the history of fungology the discovery of the "resting spore" may be a great thing, and the discoverer may deserve a somewhat less reward than the raisers of Paterson's Victoria Potato, York Regent, or the Old Fluke, for example, if those men are most deserving who confer the most practical good on the greatest number of their fellow-creatures. But, assuming the history of the fungus to be correct, and that it is as subtle as it is said to be, to talk of stamping the "spores" out of existence by burning the haulm of a crop spread piecemeal over the length of the land is about as reasonable as trying to stop the tide with a pitchfork. According to the scientists, a single spore set at liberty in a shower of rain would people a county at least with its progeny in a marvellously short period; it would therefore be a "vigorous and universal attempt" indeed, enforced ten thousand times more strictly than any vaccination or "school-board" decree, that would succeed in destroying the "spores" on every Potato patch throughout the kingdom, more especially seeing that the disease is in progress among late and early Potatoes from Midsummer to November. The silk-worm disease—quoted by Mr. Carruthers—is hardly a parallel, but the Vine mildew (*Oidium Tuckeri*), when the seasons favour its development, is just about as destructive as the Potato disease. As a matter of fact, our position now, with regard to disease, is as helpless as ever it was, notwithstanding all that has been done and written on the subject; perhaps the hopelessness of contending against the *Peronospora* has been more clearly demonstrated, if anything, of late years. To realise our true position fully is the first duty in the presence of the enemy. Mr. Carruthers suggests growing the Potato most extensively where the rainfall is the least. This is, undoubtedly, good advice; but the Potato is a paying crop, and farmers will go on cultivating it, notwithstanding the rainfall, whenever they can calculate upon an average return, taking one year with another. They can help themselves, however, by planting only on well-drained land, and, where practicable, in shallow soils. Though the results may not be always uniform, I believe it is generally admitted that the least disease is always found on the driest knolls in a field of Potatoes, more particularly when the subsoil is rocky or gravelly, and crops up to within 9 in. or 1 ft. of the surface. On such positions, too, the Potato stems are more woody and better matured, and after rain both they and the ground are soon dried by the sun and air. S. W.

Asparagus for Decoration.—Perhaps some of your readers may not be aware what fine subjects well-grown *Asparagus* makes for the table or other kinds of decoration, but I can assure them that it is well worth a trial. I grow a quantity every year, and find it excellent, whether berried or not. And, besides, by my plan an early cutting of "grass" is obtained, which, in itself, pays for any trouble that may be expended upon it. My plan (which, doubtless, can be much improved on) is as follows:—In January, I place a quantity of strong roots in pots just large enough to hold them, 48's and 32's being the general sizes used. The crowns of the plants are about half an inch below the surface of the soil, which is composed of sandy loam and rotten cowdung in equal parts, and a little sharp sand. When potted the plants are thoroughly watered, and placed on the front stage of a warm house, the crown of each plant being covered with a large 60-sized pot, and the soil is not allowed to become dry. Immediately the plants have got shoots 1 in. long, weak liquid manure is applied, and as soon as they reach the length of 3 in. in the pots are removed for two days, and the *Asparagus* is cut, leaving only one shoot, which should be either the strongest, or else a comparatively weak one, as large or small plants may be desired. As soon as the foliage begins to open fairly, the plants should be placed in a cooler part of the house to harden off a little; and from thence may be taken indoors as required. Another batch is also brought on in cold frames to succeed the first lot; and a third batch is retarded as much as possible to come in very late. During growth, liquid manure must be plentifully supplied; and it is also necessary to affix a light Hazel rod, to support the stem while growing. Every one who has seen my plants in use under the gas has been pleased with them. *Convover's Colossal* is the variety used; and, by liberal treatment, the foliage

is of a bright rich green, while the plants form a cone of foliage from the table to the top of their height; and, when laden with berries, they are really beautiful.—W. J. MAY.

Potatoes from 1 lb. of Seed.—Mr. Ford (see p. 533, Vol. VIII.) states that he had 2 lbs. of seed of each variety of Potatoes furnished by Messrs. Hooper, and that he picked from them those that would cut into most sets. Now Messrs. Hooper distinctly state that the quantity should be 1 lb., which was weighed at, and sent out from, their establishment. Therefore I consider Mr. Ford's statement at variance with Messrs. Hooper's arrangement. I had 1 lb. of each variety from Messrs. Hooper—four small tubers to each pound. Snowflake only cut into thirty-three sets, Eureka into thirty-five, and some of those were very small. I entered for the Hooper competition, but afterwards withdrew. Many gardeners, I imagine, would be glad to have Mr. Ford's make-shift system as regards manure, it being nearly as much as I can afford per half-acre, without the guano. Manure proves to be neither necessary nor beneficial, however, for the Potato crop, as it only tends to increase disease, and those that remain sound are not so good in flavour as others grown on poor soil. Messrs. Hooper, I think, did well to offer such liberal prizes, but they would, I think, have done better had the prizes been awarded according to the space of ground occupied.—W. DIVERS.

Heeling-in Broccoli.—This practice is not adopted by our large market gardeners; and yet their crops are not more injured by frost than those in private gardens. It is, indeed, exceedingly doubtful, when severe winters occur, whether any process of laying possesses any mitigating effects. Fortunately, severe injury to the Broccoli crop is the exception rather than the rule, and is quite as likely to be the consequence of imperfectly-ripened stems as of hard weather. The immense breadth of Broccoli grown for the London markets renders any process of heeling-in almost impossible. A few hundreds of plants might be so managed; but when hundreds of thousands are in question, the case is different. A neighbour of mine was engaged last spring in cutting, and sending to market for a large London firm, a huge piece of Broccoli grown in Kent; and the consignments averaged 12,000 heads per day for twenty days. Deducting some that were too much blown, and a piece left for seed, it is probable that there was a quarter of million plants in the piece; and as remarked, there was scarcely a failure anywhere. There is just now to be seen, near the Shepperton station, on the Thames Valley Railway, a splendid breadth of Broccoli, consisting of about 18 acres. Such extents as these show that market growers cannot afford to "heel in" their crops of this esculent; and yet they are in every way excellent, and failures seldom occur.—A. D.

Snow's Winter Broccoli.—I have been cutting Walcheren and Veitch's Giant Cauliflowers for the last month, but neither of these can be compared with Snow's Winter Broccoli at this time of the year. I make it a rule to keep planting out Cauliflowers up till late in September as chance crops. I go over them once a week, and all that have a flower the size of a half-crown—if the weather be likely to be frosty—are taken up and placed in frames. Should this be neglected, one night's frost of a few degrees will spoil them; but Snow's Broccoli is partly self-protecting, and much harder than Cauliflowers. I have tried most other kinds of Broccoli, but none come up to Snow's. The great point is to get it true. I have had seed of it from many, but it has been Snow's in name only. Just a word as to the difference of two plots planted with Broccoli from the same seed-bed, sown on the first week in March; the one plot from which I have been cutting was planted between early Potatoes; this ground was trenched two spades deep, and the sub-soil was loosened; rotten manure was placed at the bottom and also on the second spit. In fact, it was a piece of ground that was well prepared for Potatoes; it, therefore, answered for Broccoli with no further cultivation, and they did well, and came in some time before Christmas. The other plot of ground was dug one spade deep, using plenty of manure and a coat of soil, but the plants are small, and, as yet, but few of them are fit for use. In fact, the one plot is worth three of the other. So much for cultivation?—JOHN TAYLOR, *Hardwicks Grange*.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Welch's Giant Brussels Sprouts.—This is one of the best varieties which I have grown. Its Sprouts are not too large, but of a full medium size, and closely set on the stalks. The plants are very hardy and productive.—RICHARD NISBET, *Awarbury Park*.

Germination within the Fruit.—“D. D.” (see p. 66) asks if this is a common occurrence. A few years ago I saved some Cucumbers for seed; after they were cut, I left them in the frame for several days to ripen, and, when opened, I found that several seeds had commenced to vegetate, and, in a short time, had the fruit been split open, the seed-leaves would have been perfect. This I attribute to the heat in the frame acting on the juice contained in the fruit, which, becoming warm, had started the seed into growth.—W. DIVERS, *Wotton*.

TREES AND SHRUBS.

BERRY-BEARING AUCUBAS.

ALLOW me to thank Dr. Denny for his useful hint respecting grafting the male Aucuba on the female plant for the purpose of facilitating the production of berries. Like all really useful suggestions and processes of whatever kind, this has simplicity to recommend it, and the fact that the plan has not become general in nurseries is possibly because it has not been before thought of. I for one shall certainly graft some on the first opportunity. Would Dr. Denny kindly say what month he chooses for the operation? A large bush of the old female Aucuba, growing in a rather moist, shaded position here, was full of open blossoms one warm day in June last year, and the thought occurred to me, what a fine sight this plant would be at some future time if all those blossoms could be fertilized. While regretting my inability to do this from want of pollen, a forlorn hope presented itself. Some three years before, amongst a large consignment of evergreens, a dozen small seedling plants of Aucuba had been received, which had been planted in an unfrequented part of the grounds. Search was made for them, when they were found in the same diminutive state in which they had been received, some of them nearly eaten up by rabbits. Fortunately, two proved to be male plants, and had a few very doubtful-looking blooms on them; these blooms were secured by cutting off the little spikes entire, and it was only the work of a few minutes to touch over with them the female blossoms of the large plant. This was persevered in even after the pollen must have been exhausted, and it must be confessed, with but very faint hope of success. For months the embryo fruits remained stationary the size of Radish seeds, but did not drop off, which furnished a ray of hope. Now, however, we have the satisfaction of seeing that the experiment has taken effect, there being some scores of berries, still green, but the size of half-grown Cherries, which will, no doubt, ripen in due time. The small amount of pollen which will fertilise a multitude of blossoms seems marvellous, when both sorts of flowers are in the proper stage of maturity and the weather favourable.

Canford.

W. D.

All of us must feel indebted to Dr. Denny for relating his experience with the two sexes of the Aucuba; the following may be interesting to some of your readers. I have, in a small garden, six female Aucubas; two of these stood side by side, the branches meeting. Last spring, I placed between these a small male pot plant, having three or four flower sprays, and raised fairly above the female plant; the result is that the two, between which the male plant was placed, are crowded with berries; two others, in opposite directions, each about 6 feet distant, have a fair sprinkling; while the remaining two, of much larger size, and distant 10 and 15 feet respectively, have each a few single berries here and there. At the time of trying this experiment, I had doubts of a successful result, as the male plant, having been under glass, was considerably in advance of the females; indeed, the bloom of the former was fast withering when that of the latter began to open.—G. G., *Notts*.

Olives in the South of Ireland.—A good many years ago I recollect, says a correspondent of the “Gardeners Record,” seeing a magnificent specimen of *Olea paniculata* at Sheldon Abbey, Co. Wicklow, and if still living (which I have little doubt it is) I have no hesitation in saying that it has not an equal in the three kingdoms. *O. sativa* is also quite hardy, and well deserving of cultivation; and then we have *O. fragrans*, the dwarfest growing, and, at the same time, the most interesting of them all. I am unable to say whether it is sufficiently hardy to stand in the open border, but I have little doubt that it is; at all events, it succeeds perfectly without the slightest protection against a south wall. The flowers are yellow (all the other species being white-flowered), and delightfully fragrant, a few blossoms being sufficient to scent a large room. It certainly should find a place wherever rare and beautiful shrubs are valued. All the species like an open well-drained soil, which may consist of equal parts loam and peat. They may be propagated by cuttings of the ripened shoots in spring, inserting them in sharp sand; keep them in a close frame or pit, and place a hand-light or bell-glass over them.

Dryness at the Root in Winter.—A writer in “Moore's Rural” commenting on Mr. Groom's note in THE GARDEN, on the evil effects of over-drying plants in winter, says—“We can add, from personal observation, that injury to garden trees from excessive cold is more frequent during our American winters, when the ground is excessively dry, than when it is moist. This may indicate that the roots of trees absorb some moisture, though only slowly during winter, and thus supply the loss by evaporation from the trunk and branches; or it may be only a result of the ice in the soil, forming a covering and protection to tree roots from the severity of cold. Ice

never becomes colder than 32° Fah., while a cold atmosphere may sink far below zero. A thickness of ice on the surface of the ground may protect the roots from injury just as Esquimaux and other far northern races are kept warm in winter in huts of snow. Beneath the frozen surface there is probably also some action, though very slight, of the roots, even in winter. There must be some evaporation from the bodies, branches and twigs of trees, even in winter, and, unless this loss of moisture is somewhat supplied, trees would die and wither. With Evergreens, evaporation of moisture during winter must be very considerable, and require a large amount of moisture to prevent injury.

The True Jute Plant.—There appears to be considerable confusion as to the plant from which the substance so extensively used in the arts under the name of Jute is really derived. On investigation, however, it appears that the crude Jute comes from two species of *Corchorus*, namely *C. capsularis* and *C. olitorius*, grown principally in Bengal. Plants popularly known as Jute, however, growing in the Madras Presidency, are the *Hibiscus cannabinus* and *Crotalaria juncea*; and their fibre is not the true Jute, though hitherto considered such.

NEW PLANTS, &c.

Blanfordia flammea var. princeps.—A showy Liliaceous plant from New South Wales, having grassy foliage and erect spikes of large pendent infundibuliform flowers, elegantly six-lobed at the mouth. The flowers are very attractive in colour, being crimson-scarlet suffused with rose, and the divisions of the perianth being golden-yellow. It well deserves culture as one of the best forms of a showy group. It was introduced by Mr. W. Bull in 1873, and has repeatedly been exhibited and admired at the Metropolitan Exhibitions. "Botanical Magazine," t. 6209.

Calathea leucostachys.—This is a showy species, having oblong deep green leaves, purple beneath; it bears an erect scape of white flowers, sheltered by large revolute bracts, white above and yellow behind. The inflorescence, at first sight, reminds one of that of a *Curcuma*; and, if freely produced, we may hope to have a race of *Marantas* with beautiful flowers, as well as with fine foliage. This plant first flowered in Messrs. Veitch's establishment, in October, 1874, the plant having been sent from Costa Rica, by the late Mr. Endres. "Botanical Magazine," t. 6205.

Diurus alba.—A pretty little terrestrial Orchid, from New South Wales, where Dr. Hooker tells us the meadows are enamelled with beautiful terrestrial Orchids during the spring and summer months, thirty or forty species being found in a very limited area. The present species has a broad ovate rosy-white dorsal sepal, the lateral ones being green, striped with a chocolate line down the centre, the ovate unguiculate petals white, suffused with rose, and having a purple streak or blotch on the claw, the lip rhomboidal, of a delicate rosy colour, edged with white, and having a golden-yellow crimson-dotted crest. The foliage is Grass-like, and the tubers lobed. "Botanical Magazine," t. 6201.

Pernettya Pentlandii.—A small-growing evergreen shrub, a native of the Andes from Venezuela to Chili, ascending to near the limits of perpetual snow, and varying much in habit and flower. It has branching stems, clothed rather densely with ovate serrate leaves of white axillary *Arbutus*-like flowers, being succeeded by deep bluish-purple berries, about half-an-inch in diameter, the persistent five-lobed calyx being also fleshy, and of a glossy purple colour. This plant was raised from seeds sent to Mr. Anderson Henry from Quito, by the late Dr. Jameson. It fruits in November, and is perfectly hardy at Hay Lodge, Edinburgh. "Botanical Magazine," t. 6204.

Androsace sarmentosa.—A dwarf-tufted Alpine from the Himalayas, and growing in the Ramaon territory at elevations varying from 11,000 to 12,000 feet. It is said to be very nearly related to *A. lanuginosa*; the latter is, however, a more silvery plant—indeed, nearly white—and there are other details of habit which serve to distinguish them as garden plants. The leaves of our present plant are oblong lance-shaped, ciliate, and it has the habit of throwing out little plants at the apex of slender pink stems in a way analogous to the Strawberry or some viviparous *Saxifraga*. The flowers are bright rose-lilac, as large as a threepenny-piece, having a white eye. They are borne in trusses of ten to twenty flowers on an erect Primula-like scape, and the whole inflorescence at first sight closely resembles that of a bright, rosy, white-eyed bedding *Verbena*. It has bloomed in April with J. Anderson Henry, Esq., at Hay Lodge, Trinity, Edinburgh, and is said to be propagated with great ease by its runners which hang over the sides of the pot in profusion. "Botanical Magazine," t. 6210.

SNAILS AND HOW TO DESTROY THEM.

With thrips, red spider, and similar pests, a few of us have had to deal; but all who have a garden, or who have ever grown a Cabbage or a Cauliflower, have had to contend with snails. Dryness favours the movements of most vegetable-destroyers, but the opposite holds good in the case of snails, whose greatest depredations are committed during damp weather, and in early spring. The damage sustained by seedling Cabbage, Cauliflower, and Lettuce plants, through their ravages, is incalculable; and it is not the seed-bed alone that suffers, for, even after the plants are established in their permanent quarters, they are often eaten over near the surface of the ground and destroyed. In the case of kitchen garden crops, a sprinkling of newly-slaked lime over the parts most frequented by them forms one of the greatest obstacles that can be put in their way; but even this is ineffectual as regards annihilation. Lime should not be applied when rain is falling, as, in that case, its effects are then quickly lost. The best time to use it is in the cool of the evening, when the snails are busy at their work of destruction, and when the ground is moderately moist on the surface, or in the morning before the sun shines strongly. Hand-picking is a sure but slow plan of destroying them, and if resorted to it must be done early in the morning before they have got under cover. They dislike a sharp rough surface, and good often results from laying down a small circle of ashes or sand about 3 in. from the stems of the plants which we wish to protect. Lime may be laid down in this way, but it loses its power as soon as it becomes damp, and must often be renewed. Earthenware protectors made in the form of an 8 in. flower-pot, without the bottom, may be had, and one of these put over each plant when planted out cuts off all interference from snails until the plant has grown out of their reach. This plan is somewhat expensive at first, but cheap in the end, as the pots not only shut out snails, but if the days be hot or the nights very cold, they form an excellent protection to the plants when newly planted. Allowing decayed leaves to lie about the ground is sure to encourage snails. Their depredations, too, are not confined to culinary vegetables alone; on the contrary, there is scarcely a plant, either Alpine or exotic, with which they will not meddle. They are particularly fond of the young shoots of *Lapagerias*. Strong stems of these coming away from the root are often eaten through in one night. I have seen many attempts to prevent this happening fail until the base of the stem was encircled with zinc, or little zinc troughs holding water, a plan easily adopted, and always successful. The zinc should be about 3 in. broad, and its length in accordance with the size of the stem to be enclosed. *Dracenas* often suffer from snails eating out their tender centre leaves, and I lately saw a large *Brugmansia* with its leaves completely perforated through the same cause. Under glass they should be prevented from spreading by hand-picking, a plan which also applies to frames on hot-beds in which they congregate. They are also always to be found in abundance in Strawberry plantations, and if the season is wet when the fruit is ripening, they destroy large portions of it. Short Grass and other material laid around the plants to keep the fruit clean give them protection. J. MITT.

HEATING WITH SMALL CONNECTING PIPES.

As I see that in a recent number (see p. 60), Mr. Baines has given some hints with regard to the heating of houses, will he be so kind as to give me an answer to the following question:—Is it necessary that the connecting pipes from the boiler to the large pipes in the houses should be of the same diameter as these pipes themselves? The fact is simply this, some houses were built for me in my garden about four years ago, and a circular boiler was placed in a corner about 10 ft. below the level of the houses in question. This boiler has to warm a small stove nearest it, a pit also close to it, a large greenhouse, and a small cool plant house. The pipes in the houses are 4 in. ones, and the connecting pipes from the boiler only 2 in. ones. My gardener has complained to me each winter that he is never able to obtain an uniform heat as he wants it in each house, that in spite of the valves the heat will occasionally cool off in the one house and sometimes in another one. He attributes this to the connecting pipes not being of the same diameter as the others. I should

very much like to know whether this is the cause or not. I ought to add that the smaller connecting pipes are brought up a few feet above the boiler, and that they then run along near the back of the greenhouse under a perforated tile.

W. B. N.

Boenocks.

[It is always difficult to hit upon the exact cause of the unsatisfactory working of a heating apparatus without seeing it, especially when there may be several causes that would have the effect complained of. "W. B. N." does not state the size of boiler employed, nor does he give the dimensions of the houses to be heated by it, and above all, he gives the quantity of piping in each house, or the different levels (if there be any) of the pipes used—all matters having an important bearing upon the subject. In the arrangement of pipes I always avoid so great a difference in the size of the connections betwixt the boiler and the pipes absolutely inside the house as that which exists in the case of "W. B. N.'s" pipes, although the work may not be unsatisfactory where there are not many houses to be warmed by one boiler, or where more work is not required of it than it is well capable of performing. Unless the boiler is very small or the piping insufficient in quantity, I should scarcely think that, in this case, the inefficient working is attributable to the smallness of the connections. "W. B. N." states that sometimes one house and sometimes another gets too cold. This is, I presume, before morning, when the fire has burnt down, after being made up the night before; or, is it that the water does not circulate sometimes in one house and sometimes in another, the valves, of course, being open? If the former, I should suppose the furnace does not hold enough fuel to last throughout the night, or the piping is not sufficient in quantity; if the latter, the irregularity of the circulation is no uncommon occurrence, even where the pipes in the several houses are, as they always should be, as near of an uniform level as possible—that is, not considerably higher in one house than another. I have heated ten or twelve houses attached to one boiler, with not more than a few inches difference in the level of the pipes in the whole, and it often happened that when the valves of any of the houses in which the heat was not regularly on, were opened a little to let the water go round, it would not at first move without opening the valve almost to its fullest extent. This necessitated the man in charge staying a short time to see that the water did circulate, after which he closed the valves to the point necessary to give the heat wanted; these, of course, were houses that were merely required to be kept a little above freezing. The cause was not, as might be supposed, an accumulation of air in the pipes, but through the water running freely through the pipes it was regularly on. I have seen the same thing occur in a single house, where a flow and return pipe from the boiler entered at the middle of one end, branching right and left down each side, both exactly on a level. I had valves at each side close to the point where the pipes entered, and whichever valve was opened first the water would flow on that side so much more freely than on the other as to make the pipes doubly hot on that side; and this would continue, if we did not regulate it by slightly closing the first-opened valve even when the water was got up to nearly the boiling point. This is, however, an exceptional case, owing to the level of the pipes being so evenly balanced; and I simply mention it to show that from slight causes often arise considerable results. In "W. B. N.'s" case, if it be the coal plant-house and the green-house and Vinery that fluctuate as regards heat, the remedy will lie in a very careful handling of the valves, regulating them so as to cause the water to flow equally in all the houses just named.—T. BAINES.]

Influence of Pine Trees on Temperature.—Our greatest regret regarding Pines is, that we cannot get enough of them, or set them fast enough. We would have a line of them on the northerly side of every orchard we cared to cultivate, and on every barren or unsightly knoll, and in every spot on the farm where they would protect the fields from the fierce winds and storms of winter. There is scarcely a farm upon any sandy plain or exposed hillside that could not be made to produce more and better crops if one-eighth of the land now cultivated were judiciously planted with evergreen trees. They break the force of violent winds in summer, when the tender crops are growing, and in winter when the fields are bare. Pines seem to increase the temperature of the surrounding atmosphere. Let one try the experiment some cold, windy day, of standing for a short time on the northern and then on the southern side of a Pine grove. The difference in the climate is often as great as between March and May. The north winds, as they come down over the snow-covered hills, are checked in their course by the millions of fine, narrow leaves which hold the air stationary, like the double walls of an ice chest. It is not always the coldest air that is the hardest to bear. We all know how much colder it seems to ride against, than with the wind, on a cold day. Cold air in motion

takes the heat rapidly from everything with which it comes in contact. The heat our animals and our plants thrive in so well comes from the sun, and we should endeavour to save it as much as is within our power by protecting our stables and our fields from the fierce winds which, when unobstructed, carry away this heat and disperse it so rapidly. To this end Pines, or other evergreen trees may be planted on the exposed sides of fields or buildings with marked effect and great advantage.—"Cultivator."

The Baobab or Monkey Fruit Tree is well known from descriptions as one of the giants of the vegetable world. It rears its trunk 30 or 40 feet high, with a diameter of from 3 or 4 feet in young plants to 20 or 30 feet in the older trees. . . . They have been measured of as great a size as over 100 feet in circumference; the thickest trunk I have ever seen was 66 feet in circumference, and was clean and unbroken, without a crack on its smooth bark. The leaves and flowers are produced during the rainy season, and are succeeded by the long pendent Gourd-like fruits, like hanging notes of admiration. . . . Millions of these trees cover the whole of Angola, as they do in fact the whole of tropical Africa, sufficient to supply an incalculable amount of paper material for years.—J. J. MONTEIRO.

The Eucalyptus as an Insectifuge.—We extract the following passages from a letter recently received from Mr. C. Ballet, of Troyes, and recommend our readers to try the experiment for themselves when the season arrives.—"Lately my brother-in-law, Captain Mignard, being very much disturbed in his sleep by mosquitoes, took it into his head to place a young plant of Eucalyptus in his bed-room over night. From that moment the insects disappeared, and he slept in comfort. I have been following his example with the same result. Should this really prove generally efficacious our southern provinces will be freed of one scourge. People will use young plants of Eucalyptus instead of mosquito curtains."—"Illustration Horticole."

The Common Broom as a Fibre Plant.—The common Broom (*Spartium junceum*) is described by some as furnishing a fibre equal, and in some respects superior, to that of Hemp and Flax. In view of the great extent to which this plant occurs wild in Europe, and the ease with which it is cultivated, such an application, not indeed new, but only more recently revived, promises important results. Its fibre can be very minutely divided; and as it retains heat, it can supply the place of wool. It receives the most delicate dyes as well as an animal fibre, and successfully resists the action of acids and salt water without undergoing any change or losing its tenacity. Its strength is one-third greater than that of Hemp, while it is thirteen per cent. lighter.

The Smilax as a Window Plant.—The *Myrsiphyllum asparagoides*, commonly known as Smilax, is one of the prettiest little climbing plants with which I am acquainted. There are no large and showy leaves or gaudy-coloured flowers to attract attention, but everything about the plant, from its long, slender, Grass-like stem to its small, delicate, fragrant, white flowers, is the very perfection of grace and neatness. The roots, being small, require but little pot-room or soil, and the vines shoot up rapidly, clinging to any slight support given in the form of twine, wire, or trellis. Plants are easily procured from seed, or they can be had very cheaply of almost any florist. I do not think the merits of this neat little climbing plant are as fully appreciated as they deserve by those who take delight in cultivating window plants, as it is especially adapted to this purpose. While a majority of plants of a similar habit become large, coarse, and cumbersome when fully developed, this Smilax never reaches such a stage, but is always light and graceful, no matter how strong and vigorous the growth. It is extensively cultivated by our florists, the gentler sex being their principal customers, for Smilax enters largely into those "little nothings" which add so much to the grace and beauty of the final touches of a lady's toilet. Although the vine appears to be very delicate and fragile, it is quite the reverse, for the stems are almost as tough as wire, and the leaves remain fresh, without wilting, a long time after the twigs are separated from the parent plant, even in a warm and dry atmosphere, hence the special adaptability to the purpose named.—E. S. FULLER, in "Moore's Rural."

The Agricultural Holdings Act.—This Act is not of that permissive character generally supposed. It affects all yearly tenancies if proper steps be not taken to prevent its application. On the 4th of February next it will come into operation, and all landowners, therefore, who have not yet thought much about it will do well to consider it without delay, while time still remains for taking such steps as may be advisable. The Act does not apply to Scotland or Ireland at all; it does not apply to any holdings which are neither agricultural nor pastoral, and it has no concern with plots of ground less than 2 acres in extent. Tenancies for fixed terms, under written agreements, and already existing, stand in just the same

position as if the statute had never passed; but every new lease made after the 4th of next February will be the subject to the provisions of the Agricultural Holdings Act, unless the landlord and his tenant make a special contract in writing, which will, of course, usually be embodied as a clause in the lease, to the effect that the Act is not to apply. There are, however, in England a great many holdings which are held from year to year, or at will. In such cases if the proprietors, or, for that matter, the tenants, desire to be on the same footing as formerly, without allowing the recent statute to change their relations, then one of the parties must give notice in writing to the other before the 14th of next April, that he wishes the existing tenancy to remain unaffected by this Act. But to make clear beyond question that the principle of freedom of contract is to be everywhere respected, there is a clause, the 46th, which expressly declares that nothing in the Act shall prevent landlords and tenants from making whatever agreements they think fit, or shall interfere with such agreements. No landowner, therefore, who objects to the measure, and desires to keep out of its provisions, need be touched by it at all, if he only instruct his lawyers to draw up his leases carefully.

Some Uses of Chestnuts.—Young or ripe, new or dry, raw or cooked, reduced into flour, prepared in fried cakes, or made into soup, Chestnuts furnish a wholesome food, agreeable to the taste and easy of digestion. If boiled in water with Fennel, they do not produce flatulency. For keeping, they are either dried in ovens or in the sun, and packed away with leaves in a barrel. Our foreign imports of Chestnuts have been declining; they have ranged from 65,000 bushels to 25,000 bushels. Chestnut flour, so unknown to us in England (although there is no reason why this should be), is the staple food of many Italian peasants, with which they make their polenta, preferring it to Maize, as being more nutritious. The cost per head for this kind of food is from 3d. to 4d. per day. The Chestnut is also used whole for soup, while in some districts the flour is baked like oat-cake. A quantity of Chestnut leaves is collected from the trees, the meal being mixed with water and the leaves placed on a hot iron plate to receive the dough. It is then covered with another layer of leaves, and a hot iron placed over the whole. Infants even participate in the advantages of Chestnut meal, and are said to thrive remarkably well on food made from it. There can be no reason why Chestnuts should not be more used in this country.

Making Coffee.—The art of making coffee seems to be almost lost. We will tell the reason; it is neither bought properly, nor properly prepared for table. Here is a receipt which was in common use with our mothers and grandmothers, and will never fail to produce good coffee. First, find a housekeeper who has been so brought up that she knows good raw coffee when she sees it; next, let her buy good coffee, not send an order to the grocer for it, but personally examine and buy the coffee; next, let the coffee be roasted as often as once a week under the personal superintendence of this housekeeper. She certainly should personally see that whoever roasts it does it gradually and thoroughly, to do which she should know the colour and perfume of properly roasted coffee. The roasted beans should then be put into glass jars, tightly stopped. Then, about fifteen minutes, and not longer, before the coffee is needed, the beans should be taken out and ground, and the grist go directly from the mill into the coffee-pot, otherwise some of the much-prized aroma and flavour will pass off. Thus made, in almost any sort of pot, coffee will surely be good—as good as it used to be when our mothers made it, for this was their receipt. As to buying ground coffee, or even roasted coffee in the bean which lies open to the air, or even grinding up a lot of coffee at home and keeping it in a big box, which may be open or may be shut, and then expecting good coffee, why, to say the least of it, one might as well look for sun-beams from Cucumbers!

Boiled Celery.—Take four or five roots of Celery, which have been very carefully washed and trimmed, boil them in well-salted water for nearly half-an-hour. Drain them, place them on a hot dish, and pour good melted butter or a white sauce flavoured with a little powdered mace over them. Celery au Gratin.—Boil some Celery in well-salted water for half-an-hour, drain it, and place it in a hot dish, cover it with white sauce, and sprinkle over it grated cheese, one half the quantity of which may be Parmesan. Brown with a salamander.

OBITUARY.

Monsieur Jean-Laurent Jamin.—We regret to announce the death, in his eighty-third year, of this distinguished French horticulturist, which took place at Bourg-la-Reine, on the 13th inst. He was well known in England, and his ability as a horticulturist widely recognised in France. His nurseries are now carried on by his son, M. Ferdinand Jamin, one of the most able and best informed pomologists in France.

OPENING OF THE WESTMINSTER AQUARIUM.

This was opened by the Duke of Edinburgh last Saturday. Its main body consists of a large promenade or conservatory, wherein plants are grouped in excellent taste, the sides being occupied by rock-bound tanks, while above them the surrounding gallery is devoted to pictures and works of art. The building is 600 ft. in length, the conservatory or promenade being 340 ft. by 160 ft. and there is an entrance hall 136 ft. by 80 ft. with other accessories. The roof of the principal avenue is of iron and glass, and is glazed on the principle patented by Mr. Rendle, no putty being used, or metal exposed to the weather. Only flat glass has been used, the easy curves being the result of a succession of planes at angles corresponding with the successive radii. The total weight of glass employed was fifty tons, the measurement being 60,000 square feet. There were only two skilled workmen employed to fix the glass; they had only four labourers to assist them, and yet the work was all accomplished within a space of ten weeks. The tanks are 260 ft. by 53 ft., and will contain 800,000 gallons of water, which by a system of oxygenising will be preserved in a state of purity for an indefinite period. On the occasion of the opening 20,000 plants were employed for decorative purposes. These were disposed in groups along the sides of the hall, and the beds surrounding the fount were carpeted with *Lycopodium denticulatum*, in which were plunged irregular groups of Hyacinths, Tulips, Primulas, Cyclamens, and Lilies of the Valley in profusion; the taller plants, dotted about in other places, consisted of *Dracænas*, *Musas*, *Alcoasias*, *Richardias*, *Pandanus*, *Palms*, &c. At the front of the orchestra was a fringe of *Isolepis gracilis* and Ferns. From the galleries were suspended hanging baskets, filled principally with *Palms* and fringed with *Ivies* and *Vineas*. On the conclusion of the ceremonial, H.R.H. the Duke of Edinburgh sent for Mr. Wills, and expressed to him his great satisfaction with the floral decorations.

Trees for Portland Place.—At a meeting of the Marylebone Vestry on the 28th ult., it was resolved on the motion of Mr. Harlowe,—"That it be referred to a special committee to consider and report as to the practicability and advisability of planting a row of suitable trees throughout its entire length on each side of Portland Place." [In this situation we hope the planters will not imitate the mistake of the planters of trees in Sackville Street, Dublin, and plant them in the street outside the kerb, to the inconvenience and danger of drivers. We hope also that, for variety's sake, some other tree than the Plane will be planted; there are various other trees that would do well in the position.]

Thiers a Gardener.—M. Thiers is an enthusiastic horticulturist. He knows each flower in his garden, and treats it as a personal friend. It is stated that attending to his flowers and shrubs gives him more real pleasure than preparing some great speech or achieving some gigantic scheme. In one of the articles written by him, a short time ago, is this passage, "I think when you talk of a nobleman great and good, that the tiller of soil, the producer of what we eat, is he."

NOTES AND QUESTIONS—VARIOUS.

Gigantic Cedar of Lebanon.—Monsieur Debs, the Marquis Archbishop of Beyrout, has presented for the new Montmartre Church of Paris a gigantic Cedar, described as one of the trees of Lebanon contemporary with those of Solomon and Hiram, which was lately blown down. Twelve planks from it will soon reach Paris.

Rapid Growth of Douglas Firs.—These in a plantation here, intermixed with Deodars, made growths last season, measuring over 3 feet. The soil is marl, and I may add that the ground was trenched for their reception.—D. GILBERT, *Longmead, Bishopstoke, Hants.*

Hawthorn Caterpillars (see p. 75).—There can be no doubt that insects increase more in the environs of London than in most other places, in consequence of cats destroying the sparrows. I live within sight of Regent's Park, and used, thirty years ago, to have robins, wrens, and tomits in my garden; whereas now even sparrows are rarely to be seen.—J. E.

Large Weymouth Pine (Pinus Strobus).—A tree of this lately cut down in the Arboretum here measured as follows:—Height, 82 ft. 8 in.; girth at base of trunk, 8 ft. 4 in.; length of branches, 27 feet on either side of trunk, at 18 feet from the ground; circumference, 6 feet. It grew in tenacious clay. Is its size in any way extraordinary?—D. S. GILBERT, *Longmead, Bishopstoke, Hants.*

Paint or Varnish for Hot-water Pipes.—Can any of your readers tell me what to use for this purpose? I believe lamp-black and linseed oil will answer; but I do not know the proper proportions. My gardener used some sort of varnish which completely took the leaves off most of the plants in the greenhouse the first night on which heat was applied. I should, therefore, be thankful for some advice on the subject.—R. F. J.

To Correspondents.—"A Welsh Subscriber," "E. H.," "W. Pawson," "Recent Subscriber," "L. E. S.," "Bury," "Denman," and others, who do not send any name or address with their communications, are reminded that no query is answered which is sent without the writer's name or address, in addition to any pseudonym or initials the writer may desire to use in the paper.

"This is an art

Which does mend nature: change it rather: but

THE ART ITSELF IS NATURE."—*Shakespeare*.

THE BOUARDIAS.

THESE are nearly all natives of Mexico, and most of them have been introduced by M. Roezl; but both hybrids and sports obtained, not only in England, but also in America, now outnumber even the species; among the latter *angustifolia*, a brilliant scarlet kind, is dwarf in habit and a very free bloomer, and one which makes a valuable bedding plant, flowering, as it does, towards the end of the summer. *B. flava*, a distinct species, is bright yellow in colour; but, owing to its leaves being very thin, it easily falls a prey to red spider, if not kept in a moderately moist and shady place. Even where it blooms well, the trusses are small, seldom exceeding five florets to a truss. The best flowers are those borne by strong suckers, thrown up from the bottom. About the year 1850 or 1851, M. Roezl sent to this country several species, amongst which were *B. longiflora* and *B. Humboldtii*. *B. longiflora* still maintains its ground as the purest white kind in cultivation, and it is very sweet-scented; but it requires a little more heat than many of the hybrids and sports obtained from it. In 1855, the late Mr. Parsons, of Brighton, was very successful in raising some beautiful hybrids between *B. longiflora* and *B. leiantha*, using the latter as the male and the former as the female parent. The following four were in commerce in 1857, viz., *Rosalinda*, *Laura*, *Oriana*, and *Hogarth*. Of these, the last is by far the best, being bright scarlet. *Laura* is at times inclined to sport in colour; for example, last year I had flowers of it the exact counterpart of those of *Hogarth*; while some trusses of others have been pink, scarlet, and other shades of these colours. In the autumn of 1869, *B. jasminiflora* made its appearance; but it had been sold for some time previously under the name of *B. longiflora*, a kind from which it differs very materially; its growth, for instance, is much freer and more branching, even from the base; its leaves are longer and narrower, and of a much lighter green than those of that kind, and the flowers often consist of five, and even six petals. This is the kind so often met with in Covent Garden Market. In 1869, too, a very fine sport from *B. Hogarth*, named *B. elegans*, was imported from America—a remarkably robust and free-growing kind, its trusses and individual florets being nearly double the size of those of *Hogarth*, while in colour it is bright scarlet. In the autumn of the year just named, both *Hogarth* and *B. longiflora* were crossed with *B. jasminiflora*, and from the former was obtained *Queen of Roses*, the first *Bouvardia* with coloured flowers that were sweet-scented. It produces large terminal branching trusses of rosy-pink blossoms, that are produced for a long time in succession, and has a neat yet vigorous habit; *B. longiflora flammæ*, also obtained from this cross, is one of the very brightest of its colour, which is salmon-tinted scarlet; but occasionally some of its petals will sport to pink, especially if grown in too cool a temperature. From the cross just named was also obtained *B. Bridal Wreath*, a fine hybrid having the vigorous branching habit of *B. jasminiflora*, with finer flowers and much larger trusses; likewise *B. alba odorata*, a dwarf, compact kind, with flowers of great substance in the form of very short tubes, and, as the name implies, very odorous. The flowers, too, are very persistent, often remaining on the plant till quite dead; they are of pearly whiteness, resembling white marble. The four varieties just described were "sent out" in 1872. In that year *B. Davisonii*, a beautiful white sport from *Hogarth*, and exactly like it in growth, was introduced from America. It is an invaluable kind for bouquets or coat flowers; but, if grown in too cold a temperature the blossoms are not so pure in colour as they otherwise would be. This variety, I am told, is largely grown in America for market purposes, both in the shape of plants and out bloom. Another American kind, *B. Vreelandii*, very much resembling *B. Davisonii*, was also introduced in 1872. So much alike, indeed, are the two, as to be sometimes almost undistinguishable. Some plants from cuttings of *B. Vreelandii*

grow as strongly as those of *B. Davisonii*, while others seem more dwarf and compact, resembling, in these respects, the basketful of this kind that used to be exhibited at South Kensington, by the late Mr. Standish. In 1871, I had both *B. Humboldtii* and *B. jasminiflora* in bloom. I therefore crossed *B. jasminiflora* with the pollen of *B. Humboldtii*, and the result was about twenty seedlings, from among which the two following were selected for distribution in 1873, viz., *B. Humboldtii corymbiflora*, and *B. jasminiflora longipetala*. I also, at the same time, fertilised *B. elegans* with *B. jasminiflora*, the result being *umbellata carnea*, *umbellata alba*, and *candidissima*, all of which were good, and were sent out in 1873. Of these, *B. Humboldtii corymbiflora* is a great improvement on the parent, the latter producing but one solitary flower on each shoot, generally on the top, but occasionally on a side-shoot; whereas the hybrid now under notice bears fine trusses of flowers, varying in number from eleven to seventeen, and deliciously sweet-scented. In robustness and free growth, it resembles *B. jasminiflora*; and, if given plenty of pot-room and a liberal supply of warmth and moisture, it soon forms a fine specimen plant. Besides being a useful plant for pot-culture, individual flowers of it are also of the greatest value in bouquets, in which, when well arranged so as to stand up above the other flowers, they have a charming effect. The next in this group, viz., *B. jasminiflora longipetala*, is a distinct hybrid, the leaves of which are very dark in colour, and the habit upright. The flowers, which are pure white, are borne in dense trusses much larger than those of *B. jasminiflora*, and delightfully fragrant. Like *B. jasminiflora*, it requires a warm moist temperature to bring it to perfection. *B. candidissima* is remarkably neat and shrub-like in growth. Its flowers are of snowy whiteness, and partake of the close truss and petal of the female parent. *B. umbellata alba* is intermediate between *B. elegans* and *B. jasminiflora*, the growth being sub-erect and well branched. Its flowers are of the purest white, and the trusses close like those of *B. Davisonii*. *B. umbellata carnea* is a very great improvement upon the American variety, *B. longiflora carnea*. It is neat in habit, and bears large open trusses of trumpet-shaped blossoms, of a beautiful rosy-blush colour, the individual flowers being much larger than those of either of its parents. *B. Maiden-blush*, a beautiful soft blush-pink-coloured sport from *B. Davisonii*, was obtained in 1873. In habit and truss it is the exact counterpart of *Davisonii*, and, being distinct in colour from all other kinds, it is a great acquisition. It was sent out in 1874. *B. Van Houttei* has long, narrow, deep green leaves, and a somewhat wiry habit; its flowers, which are produced in abundance, are bright orange-scarlet in colour, and its appearance generally is so different from that of other *Bouvardias* that I am half inclined to think it is a species. *B. splendens* is a free-blooming well-known scarlet variety, dwarf in habit, and some years ago one of our best market plants. *B. Oriana lutea*, pink shading off to orange, is a kind with a somewhat weak habit, and one which produces but a small truss of flowers, of little value to any one but those who grow collections of *Bouvardias*. *B. Oriflamme* has leaves of no great size, and bears small loose trusses of cerise-coloured flowers that are rather distinct in colour. *B. bicolor*, a seedling from *B. flava*, crossed with *B. elegans*, has a habit like that of the latter, and very distinct-looking purple flowers with rosy-pink lobes, slightly tipped with white, and a centre or eye also of that colour; this variety was sent out last year. *B. multiflora*, introduced in 1874, and sent out the year after that, is described by M. Roezl as the most distinct in the group to which it belongs; it produces numerous violet-coloured flowers tipped with white, and has very small leaves like those of a narrow-leafed Myrtle. In habit it is dwarf and bushy. Besides these, many others are in cultivation, but they have, for the most part, been superseded by better varieties. *Bouvardias* of all kinds may be easily propagated in a moist warm bottom-heat of, say, 80°; cuttings made of the half-ripened wood strike best, and the soil in which they are inserted should be finely sifted, and should consist of three parts peat and one of yellow loam, with a liberal admixture of silver sand. This should be put over the crocks, which should half fill the pots, and, on the top of all, put sand to the depth of a quarter of an inch; then

sprinkle with water and insert the cuttings, which must be put under glass and never allowed to flag. As soon as they are rooted, which will be in about three weeks or so, pot them off singly into thumb-pots, and set them on a brisk bottom-heat. April is the best month in which to strike *Bouvardias* for winter blooming. All the fleshy-rooted kinds make good plants from roots cut up into pieces about $1\frac{1}{2}$ in. long and just covered with finely-sifted soil. *Bouvardias*, to succeed well, should never receive a check from the time they are potted off until fully grown. They like a genial bottom-heat and a warm moist atmosphere; if grown in a hot, dry one, red spider and green fly are sure to attack them. For the latter fumigate with tobacco, taking care that the leaves are dry before doing so; rather a close house suits them best, but they should have air on all favourable occasions, syringing morning and evening when the weather is warm and sunny. Keep the points of the shoots pinched out up to August, after which they should be allowed to grow and set for bloom. I have said nothing about shifting them into larger pots; but, of course, that must be done whenever they require additional pot-room. They should not be kept in pits or frames too late in autumn, as, in that case, the leaves are apt to damp off. The very best varieties are:—*Humboldtii* corymbiflora, jasminiflora longipetala, umbellata carnea, umbellata alba, Maiden-blush, elegans, Davisonii, Vreelandii, jasminiflora, Queen of Roses, Bridal Wreath, alba odorata, Hogarth, and longiflora. R. H. B.

THE PRIMROSES.

IN Mr. Niven's admirable enumeration of the Primroses he expresses a hope that some other contributors to THE GARDEN will supplement his remarks. From a cultural point of view it would be difficult to add anything of value to what a writer of so much experience has to say; but access to a more complete library and herbarium enables me to furnish a little additional information respecting these favourite plants. I will begin with the *Auricula*. Last year Professor Kerner, of Innsbruck, published a detailed history of the origin of the garden *Auricula*. He asserts that the true *Primula Auricula* had little to do with the cultivated varieties, whose origin he traces back to *P. pubescens*. The latter he proves to be a natural hybrid between *P. hirsuta* and *P. Auricula*. The true *P. Auricula*, Kerner states, was soon lost to cultivation, and, beyond being one of the parents of the hybrid *P. pubescens*, it has had nothing to do with the garden varieties. Possibly, as Mr. Niven suggests, the Alpine varieties are really descendants of *P. Auricula*, the characteristics of which they have retained. There are two still more diminutive species than *P. minima*, namely, *P. saxifragifolia* from Unalashka, &c., and *P. minutissima* from Sikkim, where it is found at an altitude of from 13,000 to 17,000 ft. The latter is an extremely minute flowering plant, often not more than half-an-inch high. The description of the leaves of *P. Palinuri* is quite correct, but the cut does not represent the true plant. The leaves, as Mr. Niven describes them, are broader upwards and rounded at the top—in fact, similar in shape to those of the Daisy, but more suddenly narrowed below the middle. The forms or species of the farinose section are the most widely diffused of all, and the most difficult to define, even if we confine ourselves to the wild specimens. They are found in the temperate and sub-Alpine regions of Europe, Asia, and North America, and also in the extreme south of South America. *P. magellanica* is, from a horticultural point of view, quite distinct from *P. auriculata*, an European form. In the wild specimens of *P. longiflora*, the leaves are not broader than those of several other forms described, nor are the bracts remarkably large, and the pedicels are sometimes $\frac{1}{2}$ to $\frac{3}{4}$ in. long; but the tube of the corolla is of unusual length, even in this section. *P. involucreata* and *P. sibirica* are joined by botanists, and, judging from the dried specimens, they seem to run into each other, the extremes of the Indian varieties exhibiting much wider differences between themselves than from the Siberian form. *P. purpurea* grows at an elevation of from 14,000 to 17,000 ft., and will doubtless prove a valuable ornamental plant. *P. erosa* is not usually a diminutive plant. Indeed, in stature it is equal to *P. purpurea*, of which it is regarded as a variety. *P. Stuarti* is a grand plant, and is widely dis-

tributed through North India, ascending to 12,500 ft. in Kumaon. The leaves are sometimes as much as 18 in., or even 2 ft. in length; and the flowers are sometimes borne in two or three whorls. *P. cortusoides* is widely distributed in north-eastern Asia and Japan, and I think the variety called *P. cortusoides amena* is probably a Japanese garden variety of *P. cortusoides*. Some of the Japanese specimens in herbaria have the flowers in two whorls. *P. verticillata* var. *abyssinica* is also in gardens, under the name of *sinensis* (not *sinensis*). W. B. H.

— I trust that the publication of Mr. Niven's paper on the Primroses will serve to direct increased attention to this beautiful group of hardy plants. I know of no family so well worth the attention of amateurs, indeed, of all persons who love flowers that are hardy, early, and easy of cultivation. As a rule, I think the majority of imported Primroses do best when grown in pots; certainly, whilst they are scarce, it is best to cultivate them in that way, as some kinds, once lost, may not easily be replaced. If we include the Chinese section, although not hardy, the flowering period of the family is greatly lengthened, beginning, as it does, at Christmas, and extending in the shape of the late flowering or second blooming kinds, quite into the autumn. Probably it would be safe to say that a good collection of Primroses would have some one or other of the family in flower for nine months in the year. Mr. Niven considers the variety commonly known as *P. cortusoides amena* to be one of the finest of all our Primroses; and, if this opinion were restricted to imported kinds, I think it is, without doubt, the finest of all, especially if the variety mentioned includes its variations in the form of *ilacina*, *grandiflora*, and *grandiflora alba*, all of which make beautiful pot or border plants. Mr. Niven considers that this variety is, in reality, a distinct species, and certainly it differs materially from *P. cortusoides* in its root formation, as is pointed out, and it is much hardier; but the nearest approach to *P. cortusoides* is a small white-flowered kind known as *P. cortusoides alba*, the foliage and flowers of which resemble the first-named kind, except in the colours of the flowers; but the roots are identical in character with those of *P. cortusoides amena*. If any kind had a claim to be an original species I should think it would be this white form. It is evident that the so-called *amena* is a variety exceedingly amenable to fertilisation, and, therefore, it is not improbable that the Japanese have greatly improved its original form, and perchance the kinds we now have are as far in advance of the species as our finest forms of *Primula sinensis* are in advance of the species originally introduced from China. In certain respects the variety called *amena* seems to approach near to the *sinensis* section, and, if it should submit as readily to improvement as the Chinese Primrose has done, we can hardly imagine what beautiful forms may be produced from it. As exhibition plants, the varieties of *amena* are worthy of all possible encouragement; and constructors of schedules of shows for May and June do not seem to realise what beauties they have overlooked. I hope it is not a feeling of partial nationality, but rather one of truthfulness, that induces me to express the opinion that no kinds of imported hardy Primulas can rival in beauty our choice richly-coloured forms of the *Primula vulgaris*. A perfect plant has a setting of rich green handsome foliage, and the flowers form almost a perfect bouquet in the centre, each flower being as correct in form as the severest florist could desire, and the colours are almost as various as in the Rose. Next in order of beauty come the best varieties of *Primula veris*, making either beautiful pot or border plants. For the latter purpose it is the best of all the family, as the foliage is always present, and consequently the plants are not in danger of being overlooked. This is the chief danger to which the beautiful varieties of *amena* are subject, and I can give no better advice when they are grown as border plants than that a small mound of ashes or Cocoa-fibre refuse should be placed over each clump in the winter, as this would both protect the crowns and indicate their position. Anyone who may be desirous of forming a large collection of the *Primula* family can hardly stop at mere species; in fact, the very possession of them would naturally lead to the acquisition of many of the beautiful kinds that have sprung out of them. *Primula vulgaris*,

veris, and Auricula have been exceedingly fertile in the production of varieties that have become florists' flowers, and a selection from these would naturally be desirable. They also give us the earliest and hardiest forms, and for these reasons are universal favourites. Apart from any charms the Primula family may possess for exhibition purposes, I think it is a matter for regret that no encouragement to their more extensive cultivation has hitherto been given in the shape of prizes for the best collections of distinct species and their varieties. It is needless to say that a competition of that kind would be one of surpassing interest. A. D.

Blue Hydrangeas in Cornwall.—Here Hydrangeas in shrubberies and plantations grow to a large size, and their massive heads of deep blue flowers contrast strikingly with the many shades of colour with which, in October, they are associated. It is only, however, in the shade that they are "beautifully blue;" for, under full exposure to light, they are always pale pink. I have often struck cuttings from our darkest blue plants for bedding purposes; but the flowers have invariably become pink the following season, and the same thing happens with plants of any age, if removed from a shady to a light situation, and *vice versa*. Here, therefore, change of colour in the Hydrangea does not appear to depend on soil, but rather on shade.—J. RICHARDSON, *Whiteford House, Callington.*

Boussingaultia baselloides.—I procured a single tuber of this climbing plant at Rome in April last; it resembles in size and shape that of the *Helianthus tuberosus* or Jerusalem Artichoke. On my return to England it was planted in the early part of June in my orchard-house; the tuber soon vegetated, and the stem grew so vigorously that if it had not been cut back, it would have covered a large portion of the house. The leaves are round, of a bright green, somewhat succulent; flowers conspicuous. In the first week of this month my gardener took up the plant, and found round the roots nearly half-a-peck of tubers. On the whole, the plant is very interesting, and I should be glad to know something of its properties; the tubers may, perhaps, be edible.—E. D. THOMAS.

Varieties of Scent in the Rose.—Commenting on Mr. Curtis's note to THE GARDEN on this subject, Mr. Fish says:—Several more distinct perfumes might be added, as the Macartney scent, with a dash of the more pleasant odours of a chemist's shop; the Harrisonii scent, totally distinct from that of Austrian Briar or of any other Rose; the Devonensis, sweetness distinct from all others with a dash of Souchong in it, and so unique that the writer has frequently selected this Rose in the dark from its fragrance alone. The Triomphe de Rennes scent is also distinct, as is also that of Boule de Neige and of Celine Forestier. Boule de Neige might be called the sweet-milk scent, having more of the pleasant aroma of new milk than perhaps any other Rose or flower. It also appears that the most fragrant Roses may be discovered by actual examination under the microscope from the greater prominence of their perfume-vesicles or glands. Those on the Moss Rose and Sweet Briar are almost visible to the naked eye. Judged by the glandular prominence or size test, as well as by the actual experience of the olfactory nerves, the following are among the sweetest Roses:—La France, Goubault, Devonensis, Maréchal Niel, Bessie Johnson, Madame Knorr, Pierre Notting, and Charles Lefebvre.

Gentiana gelida.—"W. T.," who made inquiries some time ago respecting this plant, will find, on reference to authentic descriptions of the species of Gentian, that whilst *G. gelida* approaches somewhat near to the habit of *G. septemfida* in growth alone, it is nevertheless a distinct species, the principal habitat of the former being the Caucasus and Iberia, and of the latter, Persia, Georgia, and the sub-alpine regions of Altai. Its height is variously given from 6 to 12 inches, but, judging from what Grisebach, the highest authority upon this beautiful tribe, has written of the similarity that exists in the general features of the two plants, the relative dwarf growth of *G. gelida* may be inferred, whilst he implies that *G. septemfida* had a more erect growth at the height he specifies, viz., 1 ft. It will satisfy the wishes of future inquirers if we state that Grisebach describes the flowers as borne in terminal few-flowered clusters, and of being of a cream or whitish-yellow colour. Dietrich, though a less reliable authority, confirms Grisebach's description as based upon the original character of the species by Bieberstein. The confusion and very general error into which many cultivators have been led respecting this rare species may, no doubt, be principally traced to the plant figured for it in "Paxton's Magazine of Botany," vol. vii. p. 5, which is a blue-flowered form which we do not recognise as a species, and though presenting the features of leaf-growth seen in the allied forms of *G. septemfida*, in respect to its assumed name it is a gross misnomer.—E. G. HENDERSON & SON, *Wellington Road Nursery, St. John's Wood.*

NOTES OF THE WEEK.

— WE hear of the erection of Winter Gardens in many places, and with regret, for the winter-garden usually turns out to be a species of elaborate public-house, with a few dusty plants here and there; such places have little in common with gardens of any kind; they only serve to degrade the name.

— MR. FANCON's flooding system of destroying the Phylloxera *f.c.*, submerging the Vines six or eight weeks in autumn, is reported to have been perfectly successful during the past season. His Vines have been exempt, while those of his neighbours have been nearly destroyed.

— THE fogs which we have had recently have been very destructive to the flowers of Phalenopsis and other warm-house Orchids, but what are called cool Orchids have not suffered so severely. The disastrous effects to which we allude are, we trust, confined to London and its suburbs.

— FLOWERING plants of the common Laurustinus, grown as standards, are now very ornamental in the Royal Exotic Nursery at Chelsea, as are also scarlet and orange-berried Aucubas of various kinds. For the decoration of greenhouses or cool conservatories in winter, these plants are well worth attention.

— CLUMPS of the broad-leaved Saxifrage are flowering freely just now in pots under glass at Kew. *S. ciliata* also forces well, and many more hardy perennials of a similar description, such as Christmas Roses, Solomon's Seal, Iris reticulata, and others, when subjected to a little heat, form excellent plants for winter and early spring decoration in greenhouses and conservatories.

— WE read in a paragraph, which is now going the round of the papers, that "a height of 200 ft. is attained by the Umbrella Pines of Italy." In Slavonia the Silver Fir (*Abies pectinata*) attains an ordinary height of 275 feet." Will any reader acquainted with the forests of the countries alluded to inform us if these statements be correct? If so, California need no longer be considered a wonderland for high trees. We believe the statement was originally published in the "Edinburgh Review."

— MR. HUNTER, of Lambton Castle, in addition to being a great Grape grower, is also a raiser of varieties of Pine Apple. He states (in "The Gardener") that his first batch of seedlings numbered thirty varieties, which were raised from seed accidentally discovered in a fruit. Since then he has systematically and successfully fertilised the flowers of the Pine Apple and has obtained seeds. He is still continuing his experiments in the direction of cross-fertilisation, and deserves success. "It takes twelve years at least to raise a stock of a single Pine Apple."

— THOSE who keep records of heat, wind, and rain, will be glad to learn that Mr. Crooks, F.R.S., has recently perfected an instrument for measuring and recording the quantity of light which falls in any particular locality. It is well known that a certain mean temperature suits certain plants, and it is equally well known that, while some plants luxuriate in bright light, others like shade. It therefore appears to us that this instrument, which is called a lucrometer, will throw light on many points in the culture of plants not before noted.

— AMONG Orchids in bloom at Kew is *Dendrobium heterocarpum*, which is one of the sweetest of all Dendrobies; also *Vanda suavis*, bearing three spikes, and a very large and richly coloured variety of *Lycaste Skinneri*, furnished with four flowers. Associated with these was likewise *Ada arantia*, bearing three spikes of rich orange or rather vermilion-tinted flowers. This plant deserves a place in every collection of cool Orchids, and is especially useful for grouping along with flower-spikes at the finer kinds of *Odontoglossa*, such as *Pescatore's*, *Rozel's*, the old *Cannabar-blotched* *Odontoglossum cordatum*, and *Alexandra*. Among other Orchids was a strong plant of *Oncidium serratum*, bearing a long flexuose spike of brown rock-tinged flowers.

— THE rock-work in the tanks at the new Westminster Aquarium, according to Nature, contains a considerable amount of Portland oolite. We understand that it was purchased from the ruins of the Colosseum, Regent's Park, as a sandstone, and it appears to have been introduced into salt and fresh-water tanks alike without investigation as to how far it is suitable. There is, in addition, a good supply of carboniferous limestone used, and in considering the conditions, it must be remembered that the water circulates constantly from tank to tank, so that the carbonate of lime will be just as present to all the inhabitants of the aquarium as to the Lamellibranchs and others it might benefit. Perhaps some of our readers can throw light on this matter, as it is not without importance to the horticulturist.

RIDGE-AND-FURROW SYSTEM OF ASPARAGUS GROWING.

PERFECT success in the cultivation of Asparagus is not always assured to the most painstaking cultivator, for it is a vegetable with marked predilections for certain combinations of soil, sub-soil, and climate, that cannot in many cases be exactly imitated; indeed, I have seen better Asparagus exhibited by cottagers, and cut from beds formed with little adventitious aid, than was produced by beds made with great care and skill, and highly fertilised. In the one case, Nature had spread out her composts of rich alluvium on deposits of silt or gravel that permitted perfect, but not too rapid drainage; in the other, strong garden soil of no great depth rested on wet and cold clay—and the influence of clay sub-soils can hardly be overcome, even when the surface-soil is re-made and brought from more favoured localities. Independent of the close character of the soil, which is inimical to the healthy development of the root, the absorption of heat is slow and superficial in effect. But, as the rich alluvial soils and the warm sandy loams so congenial to Asparagus are partial in their distribution, and less prevalent than clays and tenacious marls, and as gardens are of necessity formed on soils of every description, it follows that those who are unluckily obliged to deal with obdurate and unkind combinations must resort to schemes and contrivances that are calculated to meet the wants and necessities of the various kinds of vegetables grown upon them, and of Asparagus in particular. Cultivators of this esculent are not always successful, and I am sure I shall substantially help some by mentioning the system of growing it, first recommended by Mr. Niven, of Glasnevin (see p. 404, Vol. III.), which has the merit of being equally adapted to every class of soil and situation; it may be called the ridge-and-furrow system. It consists in throwing up a ridge, or series of ridges, of soil duly enriched, on a base of 3 ft., rising to a height of from 18 in. to 2 ft. The roots are placed on, or I may say astride, of this ridge before it is raised to its full height, and are finally covered with soil. Of course, there can be but one row of plants on the ridge, and these should be placed about 15 in. apart. The perfect simplicity of this plan, and its adaptability to the habits of the Asparagus plants, will be discovered during the first year of planting.—W. INGRAM, *Belvoir*.

American Potatoes Degenerating.—Seed Potato importers say that American Potatoes rapidly degenerate in this country, and that keep up their present character, the seed must be annually imported. This, however, is unnecessary in the case of the American Rose; for I am pretty confident that it does not degenerate. I have grown it for six successive years, and it was finer last year than on any preceding one. I am, however, aware that this variety is much affected by soil, and that, in many places, it is scarcely eatable. The competition for Lord Cathcart's prizes ought to settle the question as to the advisability of growing sorts suited to the particular locality in which they are planted; for, as will be seen, local kinds were superior, in almost every instance, to imported sorts grown beside them for competition. The aggregate returns in Lord Cathcart's competition appear to me to be anything but large; but in that of Messrs. Hooper, Mr. Ford's experience (see p. 533), fully confirms the weight of crop that may be grown from a given quantity of seed. The per centage of diseased Potatoes, both of Eureka and Snowflake, is, however, the greatest that I have seen recorded in reference to any sort, either old or new, showing that new kinds enjoy no immunity in regard to disease.—JAMES GROOM, *Henham*.

Heeling-in Broccoli.—"A. D.'s" account of the market gardeners' practice in this matter is correct; but not so his views as regards the non-beneficial effects of laying or heeling-in Broccoli that has been grown in the much more confined quarters in the generality of private gardens, surrounded by high walls and most commonly having in them members of Apple and Pear trees, and the margins of the spaces devoted to vegetables which still further tend to make winter crops of all kinds less sturdy and able to bear severe frosts. In the large open fields occupied by market gardeners there is rarely anything to prevent the air having full sweep over everything planted thereon, and the hardy character which the vegetables acquire grown under such conditions is very different from that which they have in the majority of private gardens. This is one of the many instances occurring daily in gardening matters, that shows the necessity of practice under different conditions in order to enable cultivators to discriminate as to what to do and what not to do. There are, no doubt, many gardens throughout the country in which such precautions as laying Broccoli is not much needed in the generality of Winters. In some five gardens out of six that I have had to deal with in different parts of the country, if Broccoli were left with its roots unchecked through the autumn, and the winter happened to be severe a good portion of it was killed whereas such as

was laid escaped. "A. D." may therefore rest assured that gardeners in private establishments, taking them generally, know what to do and what to leave undone as regards the different crops under their care.—T. BAINES.

Grafting Aucubas.—I believe that failure in grafting these shrubs in many instances proceeds from a scrubby branch being taken to work upon instead of a young vigorous one, and, from the fact that the grafting is left too late in the season. I have grafted scores with very few failures, and believe I was the first to practise and recommend grafting the male on to the female plant, the success of which I published years ago in the columns of a contemporary. The best time to graft is in May, when the shoots are tender. I have some grafts of the male growing on some large bushes 2 ft. in thickness, and of a greater height, standing well above the female plants, and the result is, that the plants are completely covered with berries, which are now turning red and becoming plentiful. Some grafts which I inserted in a weakly part of the bush are merely existing with one or two flower-buds, while those I speak of above have nearly fifty buds of bloom; in fact, those on strong healthy shoots are making more growth than plants of the same kind are on their own roots. The mice are the worst enemies to this shrub and its berries; they peel the bark off the branches, and we often find large bushes disfigured in this way; they will also carry off the berries in a wholesale manner, pulling off the outer rind, and burying the hard kernel until it gets softened, which I suppose they then eat, for I never can find any seedlings under the shrubs; nor can I, after the berries are cleared from the bush, discover any peeled kernels. I have seen birds peck the berries, but never saw them swallow the whole berry. I shall keep watch, and see how the pheasants treat them this season. If they should like the berries the Aucuba, would be one of the best shrubs to plant as a cover for birds.—HENRY MILLS.

A Useful Tree.—From Bahia Consul Morgan sends a translation from a book published by the inspector of the Custom House of that port, in which he gives an account of a very remarkable tree, the Carnauba Palm, which grows in Brazil without any culture, and it is so hardy as to flourish in the most prolonged drought, and has often served at such times as the means of support to the population of more than one province. The top, when young, is an appreciable and nutritious article of food; and from this tree also wine, vinegar, and a saccharine matter are extracted, as well as a kind of gum similar in its taste and properties to Sago. From the wood musical instruments are made, as also tubs and pumps for water. The delicate fibrous substances of the pith of the stalk and its leaves make a good substitute for Cork. The roots have the same virtues as the Sarsaparilla. The pulp of the fruit is of an agreeable taste, and the nut, oily and emulsive, is roasted and then used as coffee by many persons. From the trunk are obtained strong fibres, and also a species of flour similar to Maizena, and a liquid resembling that of the Bahia Cocoa-nut. From the dried straw are made mats, hats, baskets, and brooms, and large quantities of the straw are exported to Europe for the manufacture of fine hats. Finally, from the leaves is produced the wax used in the manufacture of candles; and the export of this wax exceeds £162,000 a year in value. The inspector suggests that perhaps in no other country can there be found a plant applied to so many and varied purposes.

The Calabash Tree.—One of my people has just been telling me about a tree that, he said, "grew dishes." In his native islands—of the West Indies—he has seen a tree, in height and size resembling an Apple tree, called a Calabash tree. It has wedge-shaped leaves, large whitish fleshy blossoms, that grow—where do you think?—not like those of most other fruits, on the smaller and outermost branches, but on the trunk and big branches. The fruit that succeeds the flower is much like a common Gourd, only a good deal stronger, and it often measures 12 in. in diameter. The hard shell of this fruit is cut into various shapes by the natives, and is sometimes handsomely carved. It is made into drinking-cups, dishes, pails, and even pots. Yes, they say that these Calabashes actually can be used over the fire for boiling water, just as you would use a pot. But the Calabash pot collapses after a few such trials, and is unfit for further service.—ST. NICHOLAS.

Large Seeds Best.—In an experiment made with Turnip seeds last autumn, it was found that the largest seeds produced the best plants and the largest Turnips, and that during the whole course of the experiment the plants from the large seeds preserved a conspicuous advantage over those from small seeds.

Trees in Whitechapel.—The Whitechapel Board of Works, and the other local authorities having control over the thoroughfare from Whitechapel to Bow, are to be commended for their persistent efforts to render this line of road more picturesque by the addition of trees on each side of the way. We regret, however, to say the emanations from the gas-pipes render the growth of the trees precarious.—"Metropolitan."

THE INDOOR GARDEN.

STATICES, TENDER AND HARDY.

For greenhouse and conservatory decoration Statice are invaluable, inasmuch as they bloom freely, remain in good condition for a long time, and are so easily cultivated that young plants of them may be grown quickly into fine specimens. Last year's growth made into cuttings now may be potted singly in thumb-pots in a mixture of leaf soil and sand, and placed in a close atmosphere in a top and bottom-heat of 65°, where they will root in a short time. Young plants may also be obtained by making a notch on the hard stems of old plants about 2 in. below the undermost leaves, and tying a small handful of Moss round the incision, which must be kept constantly moist, in order to induce young roots to be emitted. As soon as these make their appearance the stem should be severed from the parent plant just underneath the Moss, and it should be potted and treated for a short time as if it were a cutting. The propagation of Statice is the most difficult part of their culture; but, by following either of the methods just referred to, young plants may be had in abundance. They should, in all cases, be moved out of their cutting-pots before the roots become matted; and at this, and all subsequent shifts, the compost used should consist of loam, leaf-mould, peat, or well-rotted manure, and plenty of sharp silver sand. They may be shifted on when necessary until a 12 or 14-in. pot is employed for them, but it will take a good many years before that size is needed. They never require more than a greenhouse temperature at any time throughout the year; and, if not in bloom, they may be placed out-of-doors during the hottest summer months. Plants which have bloomed in summer and autumn should be kept somewhat dry at the root during winter, and, when re-potted in spring, they may be placed in a gentle heat until fresh growth is somewhat advanced. Statice often bloom even in 4-in. pots, and, by pinching, their time of flowering may be deferred, if a succession of bloom be desired. They blossom naturally from July until November; but, by pinching, they may be had much later even than that. The indoor varieties of them are not very numerous, and among them the best is *S. profusa*; it is not so robust as some of the others, but it forms a compact and beautiful plant, very suitable either for purposes of exhibition or for decoration, and it blooms superbly in winter. The flowers, which are bluish-purple and white, are everlasting; and, when cut, may be mixed with Immortelles. Among other good kinds may be mentioned *S. Holfordii*, *S. arborea*, *S. brassicifolia*, *S. imbricata*, and *S. macroptera*, but I like *S. profusa* best. Among hardy sorts, which bloom principally in June,

July, August, and September, are many with flowers finely diversified in colour, and in height they range from 4 to 15 in. The best for border culture are *S. speciosa*, blue; *S. incana*, alba, white; *S. cephalotes*, rose; *S. auriculifolia*, red; *S. nana*, blue; and *S. bellidifolia*, also blue. The last three are very dwarf, and well adapted for rock-work. All of them bloom profusely and grow freely in common garden soil. The dwarf varieties may be increased in spring by division, and the taller ones by means of cuttings struck in a cold frame. — J. Muir.

NEW DWARF RACE OF CINERARIAS.

This is a new strain of dwarf *Cinerarias* selected by MM. Vilmorin & Andrieux, of Paris. In diversity of colour, quality, and size of blooms the plants are described as equalling the best of the ordinary

race, while much neater and dwarfer in habit—qualities that will be appreciated by the cultivator. The care which MM. Vilmorin are known to bestow on their trials and observations renders them worthy of the confidence of the horticultural world; and, no doubt, many will be induced to cultivate this new strain, of which the accompanying is an illustration by the careful artist, M. Godard.

Dwarf *Cineraria*.

thinned soon after it is set, or the tree would probably suffer from over-cropping. The fruit ripens the year after it is set, early or late, according to temperature. If intended for dessert, it is best gathered as soon as it is fully coloured. The trees do best planted out in prepared borders, as, in that case, the roots are not subject to sudden or extreme variation of temperature, like those in pots or tubs. This is a subject which should receive more attention than it hitherto has done; for it requires but little experience to see that the top of a plant will stand much greater fluctuations of temperature without injury than its roots. In the case of Pines, for instance, it is abundantly proved that they may be safely wintered in a very moderate temperature, if the roots be kept active by being planted out in a temperature approaching that of their native country; even our hardest forest trees have their roots better protected than those of Orange trees in tubs in unheated structures.—JAMES GROOM, *Henham*,

Home-grown Oranges.—Those produced by trees planted out in the conservatory here are equal, at least in appearance, to the best imported fruit. The crop, which is nearly ripe, is abundant, thus combining, in a striking manner, the useful with the ornamental. The temperature of the house in which the trees are grown is kept at 50° in winter, but as cool as possible in summer, in order to preserve the beauty of the blossoms of flowering plants as long as possible. As the Orange tree is a very free flowerer, the fruit has to be

FORCING ROSES.

THE Rose is the best flower in the conservatory in the month of March; the atmosphere is cool and bracing, never over-hot; fire-heat is not wanted, and the Rose-bloom lasts long; it comes slowly forward from the bud and does not fade so suddenly as under a hot sun; and some think it even smells sweeter than in summer. To have pot-Rose blooms in March is a much severer trial to the plants which bear them than if the same plants had to perfect the crop in May. The question is sometimes asked why Roses like those staged at the great shows in May and June are not forthcoming in March; the reason is simply that, for the latter month they must be forced to a greater extent, and under less favourable conditions of light and air. The Rose, like many more hardy flowers, must be forced slowly; its energies must be economised, more especially if its previous management has not been of the best. Slow forcing is always to be preferred under any condition of the plant, as it enables it to produce the finest possible flowers. We once made a grave mistake with a very fine horse: we started late on a long journey which had to be performed against time; thoughtlessly, and in our anxiety, we allowed our driver to overtax the animal the first few miles, when he all but broke down: the journey was done within the time, but with sadly wasted energy, whereas if it had been done with more economy of the whip at first, and at a slower pace, the drive-up at the journey's end would have been more brilliant. So with the Rose: if a brilliant drive-up to the conservatory be desired, spare the whip in the forcing-house. The Rose is no exception among plants, especially those of a hard-wooded nature, which require a thorough good preparation: indeed, good management during the twelve months preceding the time it is intended to commence forcing should be faithfully carried out; and therefore we think it is not premature to call attention to the subject thus early. The success attending the forcing process, the amount and quality of the crop of flowers, will be found in direct proportion to the condition the plants are in from the previous summer's management; and the experienced grower can tell when and wherein his management has been at fault, should success not have been complete. Charles Lawson, a very robust and usually a sure and excellent forcing Rose, will, from the fact of his very stout constitution, provokingly give the grower the slip if his summer management have not been thoroughly performed. The rule should be with Roses as with Vines and Peach-trees—to preserve the foliage in good health free from insects, and keep the plants well supplied with nourishment, so that when they are enjoying the ripening influence of the sun they are not scorched and exhausted. From the very time the foliage is developed in the forcing-house till they shed their leaves in autumn, they must be a chief care. The period in the conservatory, if it be dark and ill-ventilated, is dangerous and often disastrous for the next season's crop: overcroding should be avoided; the Rose-plants should have every advantage possible of sun and fresh air; this is often impracticable in dark, ill-ventilated conservatories, where small plants are necessarily far from the light: in such structures Roses must remain but a short space. A span-roofed show-house with elevated stages is the best position for them. Those now in the forcing-house with their foliage becoming well developed, and showing their flower-buds in a rudimentary state, should be supplied with a little weak liquid manure, until they have done blooming, provided they are not over-potted; the pots should, however, never be out of proportion to the size of the plants, but well filled with roots like Strawberry plants when introduced to force; they will flower better in this condition, and be more benefited by regular manure-waterings. Caution is necessary in removing Roses from the forcing-house to a cooler house, if such house be really cool and airy; if the change be too sudden as regards temperature, there is a danger of the buds turning yellow and dropping off, or at least proving all but abortive. They must have the benefit of an intermediate temperature for a few days, always taking care that they are near the light, as they quickly get drawn in if in the least shaded. Green-fly is sure to be troublesome, and must be destroyed at once; sometimes the Rose-grub will make its appearance, and must be looked after at short intervals; it curls up the leaves and eats out the buds. It is, however, not a formidable enemy; a slight pinch of the suspected leaf between the finger and thumb settles it. Roses which have been forced must have constant attention after flowering in the matter of cleanliness, care that the foliage is not damaged, and a continuance of liquid manure up to the middle of May, when they may be stood out-of-doors thinly for a few weeks in a sheltered place. Early in June they will all require to be examined, re-potting those whose pots are well filled with roots, and where the size of the head justifies it, into pots two sizes larger; some may only require the drainage examined, and the effete soil removed from the surface and then top-dressed; some may require the ball of soil reduced, and placed into smaller pots. We prefer pot Roses to be on their own

roots; but if any be on the Manetti, suckers must be looked sharply after. If there be a tendency in any plant to throw up many suckers, and the head be showing signs of decadence, the plant may be thrown to the rubbish-heap at once. The soil best suited to the Rose in pots is a light yellow loam, slightly inclining to clay, with a few bones, and a mixture of thoroughly rotten cow-manure. For Tea Roses a proportion of thoroughly decayed leaf-mould should be added. After potting they should be plunged in leaves or sawdust in a sheltered situation fully exposed to the sun, where they must be well supplied with water. They will soon start into growth, and will show flower-buds persistently—we refer to hybrid perpetual Roses; those buds should be pinched out as soon as they appear. If some should become top-heavy and likely to be tossed about by the wind, they must have one or more stakes attached to them. Towards the end of September, it will be found necessary to lift them out of the plunging materials, and during heavy rains lay the pots on their sides; or, better still, give them the shelter of glass by introducing them into a thoroughly ventilated glass screen or orchard-house, and keep them moderately dry at the roots, when the wood and foliage will ripen, and the latter drop. For the winter, we find it best to plunge them in the open air in the south, over the pots in coal-ashes on a dry bottom. It is as much a mistake to keep pot Roses too dry in winter, as it is for Vines, Peach-trees, or Strawberries in pots; over-dryness exhausts them. Probably, all things considered, a coal-pit would be the best place for them—they would not get too dry, nor be exposed to cold rains or frost. By Christmas the first lot should be pruned before introducing them to heat: all weak shoots should be cut out; they are useless in outdoor Roses, much more so in Roses to be forced; shortening medium growths well back to two or three buds. Strong shoots from near the bottom of the plants should be left two-thirds of their length. Much depends on the variety of the Rose; some are robust growers, even in pots, such as Charles Lawson, Baronne Rothschild, and Jules Margottin; these soon become large bushes. Some never grow strong though fine forcing Roses, yet require close pruning, such as La France. Before introducing into heat they must again be examined at the root to see if the drainage be right, and the surface top-dressed with rotten cow-manure. Our first lot is always started on an elevated stage in the early Peach-house; the slowly rising temperature of this house seems to suit them admirably. Syringe twice a day with the Peach-trees, unless the weather be rainy or particularly dull, requiring very little water for some time, until the foliage becomes developed. Of varieties suited for forcing, there are none sweeter and more beautiful than the old Moss and common Cabbage Roses; they are, however, very much of one colour. Among hybrid perpetuals there is every variety of colour, from pure white in Baronne de Maynard, to the darkest crimson in Duc de Rohan. The following are a few very good varieties for forcing:—Duke of Edinburgh, Edward Morren, Fisher Holmes, John Hopper, Madame Alice Dureau, Madame C. Wood, Madlle. Annie Wood, Senateur Valise, Alfred Colomb, Comtesse de Chabrillant, Coquette des Alpes, Dupuy Jamin, but really, all hybrid perpetual Roses force well.—“The Gardener.”

Carguata muscaica.—A short time ago, says the “Illustration Horticole,” we mentioned the flowering of this handsome Bromeliaceous plant, which it will be remembered, was introduced by Mr. Linden, and sent out under the provisional name of Tillandsia muscaica. There is now no longer any doubt that the presumed Tillandsia is a true Carguata, and henceforward it will bear the name of muscaica. At some future time we shall publish a corrected description of the species, which we have submitted to Professor Morren, who, as is well known, is learned in all that appertains to the Bromeliaceae, and who is just putting the finishing touch to his work on the tribe Tillandsiæ, for early publication.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Paint for Hot-water Pipes.—If “R. F. J.” (see p. 120) paints his pipes with what is known as Brunswick-Black, he will find it to answer the purpose perfectly, and to be productive of no bad results.—J. Murr.

—As paint or varnish for hot-water pipes, I find nothing to answer so well as lamp-black and boiled linseed oil. The lamp-black should be made red-hot, and when cooled should be beaten up very fine, adding oil until the mixture is sufficiently thin to be applied with a painter's brush. The pipes should be warm during the application.—RICHARD NISBET, *Asbury Park*.

Preserving Woodwork of Glass Houses.—The chief cause of decay in forcing houses is allowing moisture to get into the wood, through neglecting to paint it and not providing means for the ready escape of water from the roof. Where the roof lights slide in a groove—where water is sure to collect, if both sides be solid; but if stout wooden pegs be used on the outside or sloping portion of the sill, they keep the sill dry. Badly-constructed houses are dear at any price.—JAMES GROOM, *Zenham*.

THE FRUIT GARDEN.

TOP-DRESSING FRUIT TREES.

THERE is no operation in the garden more recommended, or one which is of more general utility, than top-dressing the soil as a means of enriching it for the benefit of the roots of trees. The richer the material used, the more effectual it is for good. On the other hand, the mixture of manure with the soil in which fruit trees grow is generally deprecated, yet we are constantly hearing of the great fruit-growers for the London market systematically manuring the land in which their fruit trees are growing, which fact necessarily leads to the inquiry, Which is the most judicious practice, and most fraught with ultimate success? On the one hand, when the ground is well manured, there are rocks ahead to be avoided in the shape of coarse immature growth, canker, and scanty crops; on the other, where manure is eschewed, there are dwindling trees, small-sized, or cracked and spotted fruit. To make a reasonable deduction between the two systems, it may be safely assumed that the market gardener knows which pays him best. If common sense be appealed to, it might be inferred that heavy and regular crops could not be obtained from fruit trees without liberal culture, no more than from beds of Strawberries, Raspberries, or other bush fruits. A liberal use of manure no doubt has the effect of encouraging an abundant growth of wood; and, however much it may be desirable in many circumstances to repress this growth, still the balance is in favour of a liberal use of manure, with all its supposed disadvantages. The growth of fruit trees can be modified and regulated by a judicious plan of summer-pruning and training in the case of dwarf bushes and espalier trees, thereby inducing a fruitful habit, even with vigorous trees. Orchard trees will take care of themselves at the top, with an occasional thinning of the branches. The half-starved tree will be more floriferous in spring than the full-fed tree, and may even yield fruit in greater quantity; but, in point of quality, there will be no comparison. Fruit trees in private gardens are too often left to themselves, so far as attention to their requirements at the roots are concerned. Accidental circumstances may sometimes be in their favour, as, for instance, when the land has been heavily dressed for some green crop in contiguity to the trees, they receiving a passing advantage from the manure not intended for them. I feel self-accused in this respect; and, in illustration of the remarks already made, will mention first the case of three long lines of dwarf Apple trees, which have been abundantly fed in the chance way adverted to, the border being cropped with such things as Lettuces, Coleworts, Endive, and Shallots, which received heavy dressings of manure. The trees grow very strongly, and the crops are moderate, but always of the largest size; the trees are kept dwarf and spreading by having their branches annually tied down to a hoop of strong wire fastened to a circle of stumps driven into the soil after the manner that a specimen plant would be trained in a pot; the annual shoots are not much shortened, but the old wood is cut out; these young bent-down annual growths invariably make abundance of fruit-bearing spurs, and when not pruned back, the tied-down shoots absorb the energies of the trees. This tying process necessitates considerable labour, but is amply repaid by the crop and the neat-looking appearance of drooping trees. Again, several long lines of espalier Pear trees were planted, and trained to strong wires stretched between the usual cast-iron columns. They all received the same treatment at planting time, each had half a load of yellow loam to start with, and it was thought this would be sufficient for their welfare for several years to come. Circumstances seemed equally in favour of the whole at the time of planting, but, as years passed on it became evident that the growth and bearing qualities of the trees were altogether dependent on the management the borders received for their annual crops. A piece of the Pear tree borders was annually used for the culture of summer Lettuce, and consequently heavily manured; at this place the espalier trees shot ahead of the others, and bore fruit of superior quality. Another piece of the same border was occupied chiefly with spring-flowering plants for the flower garden, and

with plants for early forcing, such as Deutzias, Dielytras, Pinks, &c., which received no manure whatever, only occasionally some fresh soil; the trees soon began to stagnate and fruit indifferently, the greater portion of the borders were occupied with herbaceous plants, annuals, and summer flowers for cutting, which were annually dressed with some light manure, such as old Mushroom manure. The difference in the growth of the trees, and of their fruiting qualities, was so strikingly in favour of the manured portion that it was resolved to take the whole of the others in hand, and see what could be done to assist them. With this purpose in view, the whole of the borders were cleared, for the time being, of all plants, the soil over the roots of the tree removed, from the boles outwards as far as fibrous roots were found, to a distance of from 6 to 8 ft.; the roots were not disturbed, only laid bare as far as possible, and each tree had one or more barrow-loads of very rotten, cool, horse-manure, spread equally all over its roots; over that again was spread a layer of half-rotten cow-manure; the roots, it may be remarked, were found to have laid hold of the fresh yellow loam, but it evidently was not sufficiently rich of itself to maintain the vigour of the trees. After the top-dressings the soil was partially returned over the manure, and the ground re-stocked with plants. The result is looked forward to with great interest, as the carrying out of the idea was undertaken from the cultural necessity of the case, and was prompted by the improved condition of the trees growing in the manured border. Top-dressing can be applied to orchard trees on Grass with the perfect confidence that improved crops will follow, although the Grass itself may be the first to show the benefit of the top-dressing. There is before us an instance of an orchard of Apple trees planted on thin gravelly soil; the trees were covered with Moss and stunted, although not by any means old (about twenty-five years). The Grass of this orchard had been mown year after year for the sake of tidiness, thus exhausting the soil more than the trees did. A rather rough system of top-dressing was inaugurated at a sacrifice of appearances, all sorts of refuse material were wheeled or carted into the orchard and spread over the surface, such as sifted coal ashes, old decayed tan, the old soil and rubbish from the potting bench, sweepings and scrapings of roads, &c., until a considerable thickness of material had accumulated. The first result was a troublesome growth of Grass, which was kept down with the scythe, but not cleared away—on the contrary, allowed to rot on the surface. By-and-by the trees began to emit quantities of young roots from the lower parts of their boles into the top-dressing, and the second result was that the next crop of Apples was considerably larger and of a much improved quality; the branches were severely thinned to admit light and air, well dusted with quick lime to remove Moss and Lichens, and they were amply repaid annually by this simple attention.

W. D. C.

CRACKED PEARS.

SOME time ago, we had splendid Pears, but for the last three or four years they have become cracked and hide-bound when about half their proper size, have no flavour, and do not keep so well as they used to do. The trees are about twenty years old, have been root-pruned, and all sorts of recommendations have been followed in order to resuscitate them, such as fresh earth, burnt ashes, old irons buried at the roots, roots lifted, mulched, and watered, and yet nothing has done the least good. Some young trees, too, are worse than the old ones. Surely some one wise in gardening matters ought to know what should be done to effect a cure. I propose to slit the bark longitudinally, as I fancy it is too hard to allow the sap to ascend in sufficient quantities to enable the fruit to swell. Some say it is the result of a cold spring, hail, wind, &c.; but the weather is no worse than it was ten years ago. I therefore trust that some remedy for my trees may be found.

G. G.

Tallow.

[Everything seems to have been done to these Pear trees in the way of root-pruning and renewing the soil about them, but without the desired effect on the fruit. There is little doubt but that the Pear-mildew is the cause of the fruit cracking, and this year it has been more prevalent than usual, owing to the very wet summer and autumn. This year with me the Beurré Diel and Glou Morcean

were so cracked by mildew that they were unfit for dessert; also some other kinds not so valuable. I have headed some of the trees down, and scraped the rough bark off, and afterwards painted the branches with a mixture of soft soap, sulphur, and lime, with some clay in it to make the composition stick. Where the trees are supposed to be hide-bound, scoring the strong branches longitudinally will do them good, as I often serve Peach and Nectarine trees in this way with good results to the circulation of the sap. The Pear-mould is more to be seen on trees grown on strong undrained soils, and more on standards than on wall trees. I should advise some of the Pear trees at Glanatore to be painted with the above mixture; and, to be effectual all the strong branches should have the rough bark thoroughly scraped before it is put on.—WILLIAM TILLEY.]

Preserving the Flavour of Apples.—Apples ought to have as sweet an air in their winter home as any other kind of food. They take in, very readily, the musty odours of close, moist cellars that are little better than vegetable pits; and the difference between a crisp, high-flavoured Apple, and one that is flabby and poor, is often simply the difference in the storage which they have had. This fruit needs gentle handling, a cool, dry room, just safely above the freezing point, and removal from all rank vegetables or unpleasant odours.

Gooseberries for Exhibition.—As this is the season for pruning Gooseberry trees, it should be borne in mind that there is a material difference to be observed in the pruning of those trees upon which it is intended to grow large fruits for exhibition and those from which fruits for the dessert or culinary purposes only are required. One of the leading exhibitors in the north thus sets forth in a contemporary the practice for pruning trees, the fruit of which is required for show:—"Not nearly so much wood should be left when good fruit is wanted for exhibition as should be allowed to remain under ordinary circumstances. Indeed, where large fruit is desired, no weak shoots whatever must be left, and the strongest should be shortened to within 5 or 6 in. of the previous year's growth. The superabundant wood should be taken off in such a manner that the strong shall be left at regular distances from each other, and if of these many be suffered to remain, the plant will become overcrowded with foliage and new wood, and the fruit will therefore be deprived of the requisite amount of light and air." While thinning, in all cases to an outside bud, do not cut all the shoots clean off, but leave about half an inch at the bottom of some to form what are called fruiting spurs. The leading points of excellence which belong to a show Gooseberry are, a smooth and thin skin, round form, sweet luscious pulp, long thin stalk, large size, and small nose, *i.e.*, the decayed blossom. As to colour, red is esteemed first, yellow second, green third, white last. With show Gooseberries weight, and not beauty, is the object. A Gooseberry that is a little rough is not considered, imperfect at an exhibition where the awards are given for the heaviest berries; but where handsome berries are required, this roughness is considered an imperfection.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Position of Span-roofed Vinery.—What should be the position of a span-roofed Vinery as regards the sun? I am about building one, and shall be glad of the information.—L. I. S. [It should run due north and south, so that one side catches the morning and the other the evening sun.]

Planting Orchards (W. B. F.).—We should search the ground to about 18 in. deep, and loosen the bottom of the trench another spit, but not bring to the surface much of the previously unmoist soil. It would be desirable to give plenty of rotted manure, well mixed with the soil used for planting.

Grafting Vines (Amateur).—This should be done when the house is started, pulling in the grafts by which grafting, and on the upper side of the rods. Have two eyes to the scion, using good grafting wax in preference to clay, bind over the junction with a little Moss, and sprinkle with water occasionally.

The Reineette du Canada Apple.—Some of the finest Apples seen in Covent Garden Market this winter have been the Reineette du Canada. This variety is a capital grower, and, as the tree comes into flower about a month later than most others, a crop is almost certain. Gloria Mundi, grown in Hertfordshire, has also been very fine this season. The fruit keeps well, and one is sometimes large enough for a full-sized dumpling.—F.

Autumn-fruiting Raspberries (see p. 113).—Some years ago I had the following kinds from Messrs. Rivers, Sawbridgeworth, and I can recommend them as the best in cultivation, *viz.*, Merveille de Quatre Saisons Rouge, or October Red, Merveille de Quatre Saisons Jaune, or October Yellow. These two varieties fruit freely in warm dry summers and autumns. There is a black autumn-fruiting variety likewise to be purchased, but it is only a shy fruiter, and not of good flavour.—WILLIAM TILLEY, *Wellbeck*.

The Wellington Apple.—This is one of our best late-keeping culinary Apples, lasting, as it does, in good condition almost as long as any Apple with which I am acquainted, and, when baked, scarcely changing colour. I observe that our Apples are much superior in this respect to sweet ones, which almost invariably assume a dull dark colour in cooking. This sort is also an abundant cropper, hardy, and equally satisfactory as a standard, hybrid, or espalier.—A. GOSW, *Leitham Hall*.

BAYHAM ABBEY GARDENS.

THE fine old ruins that still exist at Bayham are well worth notice, not only as remnants of the architecture of the twelfth century, but also as illustrating how ancient buildings of that kind may be rendered interesting in park or garden scenery. Our engraving gives what may be called the principal view of the structure as it now stands; but it conveys but a faint idea of the freshness, even in winter, of the green turf that surrounds it, or of the beauty of the Ivy which clusters in heavy masses around its old gables and ruined towers; while in spring, we are told the crumbling walls are, in many places, golden with Wallflowers, which have naturalised themselves here, as on many other monastic ruins. Later in the season, Banksian and other evergreen Roses peep out from these Ivy-covered walls, which in autumn are rendered brilliant by means of Virginian Creeper. These old remnants of a bygone age are situated in a sheltered valley, hemmed in on all sides by well-wooded hills; close to the ruins stands the old mansion, in the grounds connected with which we remarked some very fine old trees, most of them grey with Lichen. Here a Tulip tree with a forked trunk is fully 65 ft. in height, and close beside it grows a Scotch Fir, 6 or 8 ft. taller, its smooth red bole being nearly 2 ft. in diameter. Here also is a veritable wild garden of Roses and other flowering shrubs, allowed to ramble at their own sweet will. Among other trees we observed near the entrance to the ruins an old Pollard Ash—now in the last stage of decay; but one which has evidently been, in its time, a noble specimen—with a bole 10 or 12 ft. in diameter. Associated with it was likewise a very old Cornelian Cherry (*Cornus mascula*) about 15 ft. in height, much cankered and smothered with grey Lichen, yet well set with blossom-buds. The pulpy fruits of this tree, which resemble a Cherry in colour, grow to about the size of Olives, for which, in the olden time, they were not unfrequently substituted. The flowers are still sometimes used for flavouring sherbet, and in Germany are eaten in the form of sweetmeats or tarts. On still, sunny days a beautiful view of the ancient gateway leading to the ruins may be obtained from the old Tulip tree just mentioned, the arched masonry reflected in the water of the river, which formerly formed the moat, contributing not a little to the effect. The grounds attached to the new mansion, which stands on a hillside at a considerable elevation above the ruined priory just alluded to are but newly planted, but the park-like scenery for many miles around is beautifully undulated and well wooded. The prevailing trees in the surrounding woods are Oak, Ash, Spruce Firs, Birch, Scotch Pine, Beech, and a few Chestnuts. Larches are also numerous, and among these we noted some very fine specimens. Some of the largest of the Spruce Firs are also striking specimens, being drooping in habit and feathered to the ground with branches. From some stumps of Spanish Chestnut felled a year or two ago young growths had pushed up in the form of round masses 6 or 8 ft. in height, and these being still clothed with russet-coloured foliage had a singular effect contrasted with their green surroundings in the shape of Hollies, Spruce Firs, and Yews.

Kitchen Garden.—An old kitchen garden lies near the ruins of the old priory. In this two or three beds of Asparagus are known to have occupied their present site undisturbed considerably over a century, and still they yield excellent crops. It is probable that as the old plants die out self-sown seedlings have occupied their places, their vigour being insured by copious mulchings of well-rotted manure. Be this as it may, the produce from these old beds is preferred to that from newer ones on account of its superior flavour. The new kitchen garden occupies the sunny slope of a hill above the mansion, and is a little over 2 acres in extent. It is bisected each way by convenient walks, and the plant and fruit-houses occupy the south side of the back wall, the whole being surrounded by fruit tree and vegetable borders. The walls are well furnished with healthy young trees, such as choice Pears, Plums, Cherries, and Peaches, and the intersecting walks are also margined with select varieties of bush or pyramidal Apples and Pears. The soil here is a light-yellowish loam on red sandstone rock, and the situation being elevated, the effects of spring frosts are but slightly felt.

VIEW IN THE GARDENS AT BAYHAM ABBEY, KENT.

Plant and Fruit Houses.—These, which have scarcely been erected two years, are light, commodious, and well-finished structures. An early Peach-house and two Vineries are well stocked with healthy Peach trees and Vines, the latter especially having made vigorous, short-jointed, and well-ripened growth. In the stoves we noted, among other plants, specimens of *Alocasia macrorhiza variegata*, 12 ft. through, *Maranta* (*Calathea*) *zebrina*, 7 ft., and some good *Dracænas*, *Gymnogrammas*, *Pandanus*, and *Livistonas*. The roof is partly covered with *Allamandas*, and in one of the houses *Bougainvillea glabra* grows and flowers remarkably well, and even now it bears several trusses of its glowing mauve-coloured bracts. This plant is so distinct in habit and colour from anything else that it well deserves a place in every warm plant-house. Small decorative plants, such as Ferns, *Cyclamens*, scarlet-berried *Solanums*, *Dracænas*, *Primulas*, *Tree Carnations*, *Aphelandra Roczii*, &c., are extensively grown for drawing-room and dinner-table decoration, while *Gardenias*, *Euphorbia jacquiniæflora*, *Dendrobium nobile*, *Bougainvilleas*, *tree Carnations*, *Narcissus*, and *Hyacinths*, come in conveniently for cut flowers. Mr. Johnstone finds *Aphelandra Roczii* very useful, small plants in a 60-sized pot being strikingly effective when in bloom, and as their flowers open in gradual succession up the erect spike, they last in beauty several weeks. It may not be generally known that this plant seeds freely, and that this is the best method of propagating a stock of it, as the seed germinates readily, and the young plants grow freely in a warm stove, while their winter-blooming habit makes them still more valuable.

TREES AND SHRUBS.

BEST TIME FOR TRANSPLANTING TREES AND SHRUBS.

On this much-disputed subject even practical planters of considerable experience differ materially. Many will, however, be ready to assert that, with proper care and the necessary appliances, transplanting may be successfully accomplished at any season. But the bare assertion, although it may be true, fails, nevertheless, to answer the question. If trees and shrubs of considerable dimensions could be transplanted from one spot to another without injury to the roots, or the destruction of a portion of their delicate fibres or feeding organs, it might then be immaterial at what season the operation was performed. But as these easily-injured and delicate organs, in their search for suitable food, rapidly extend themselves to considerable distances from their stems, it is difficult, if not impossible to remove them without breaking off a considerable portion of these feeding organs; and, although the roots are, doubtless, possessed of the power of absorbing nutriment from the soil, still the inevitable sacrifice of a considerable portion of rootlets and fibres must necessarily give a check to, or inflict an injury upon, the plants subjected to the operation of transplantation. Hence the question naturally arises, When are plants generally in the most favourable condition to resist the effects of this injury, and to commence the process of reparation? Some planters recommend early autumn planting; others prefer the spring, more particularly for evergreens; while others recommend the performance of the operation during mid-winter, or when the plants are in a dormant condition. The latter practice, which is the least worthy of recommendation, I will first endeavour to consider; and it must, I think, be evident that, should the roots of plants get seriously injured during transplantation, the healing process cannot be expected to proceed otherwise than slowly, if at all, during winter. There is even reason to apprehend danger of ultimate decay being induced by the low temperature of the surrounding soil and the inactive condition of the plants. It will, of course, be understood that these remarks apply to the transplanting of trees and shrubs which have attained to considerable dimensions, and whose roots have not for some time been disturbed, and not to the transplanting of ordinary nursery stock, which has annually been subjected to removal, as well as to judicious root-pruning, which has the effect of inducing the production of rootlets, or feeders, near to the stems, whereby transplantation is rendered comparatively safe

at almost any time from the end of October to the beginning of May. As in some degree illustrative of the ill effects resulting from the disturbance and consequent mutilation of roots at a season when the plants operated upon must necessarily remain for some time in a dormant condition, may be mentioned the circumstance of potting up a number of deciduous flowering shrubs, during the latter part of December, consisting of Persian Lilacs, *Weigelas*, *Deutzias*, *Spiræas*, &c., about one-half of which were at once placed in a forcing-house of moderate temperature, while the other moiety were placed in a cold pit with the view of forming a succession, and, after remaining there for about a month, were shelved in the same house as the former, and subjected to a similar temperature, but did not by any means succeed so well, although they had the advantage of increased light and a more advanced season. The plants which were introduced into a growing temperature as soon as they were potted at once commenced the process of reparation; while, in the others, a suspension of vital power was induced by the low temperature, and the healing process was not only retarded, but decay of the injured roots had in many instances taken place, and this was distinctly visible on their removal from the pots.

The practice of late spring-planting appears to find favour with some planters, more particularly as regards evergreens, which differ to some extent from deciduous trees, inasmuch as their roots are generally in a more active condition during winter, on account of the continuous demand made upon them by their leaves. There is, however, no absolute rest for deciduous plants more than for evergreens, unless it be during periods when the soil in which they are placed is in a frost-bound condition, as, in the middle of winter, the gradual development of buds is perceptible when the weather is open; in fact, there does not appear to be any reason for supposing that the best season for transplanting evergreens is not also the best for moving deciduous trees. Much, however, of the occasional success which attends late spring-planting is to be ascribed to local or other circumstances. In some localities, where the soil is of a stiff and retentive nature, trees and shrubs, whether deciduous or evergreen, may be lifted with balls of earth adhering to their roots, of dimensions corresponding to the size of the plants; and if they be re-planted with as little delay as possible, to prevent any injury from being dried up by the sun or wind, the balls of earth will generally contain a sufficient undisturbed portion of roots and rootlets to supply for a time the swelling buds or foliage of the plants; and, should the weather set in mild and damp, the plants will be materially assisted in forming fresh roots in abundance. In many less favoured localities, however, where the soil is of so light and sandy a nature that it is impossible to get a sufficient portion of it to adhere to the roots, and where cutting east winds generally prevail during the greater part of April and May, together with the rainfall of the former month, the smallest of any month in the year, late spring can hardly be recommended as the best season to transplant trees and shrubs. Many years ago I superintended the transplanting a number of the more common kinds of Conifers, during the early part of the month of August, and during very dry and warm weather. The trees were mostly from 10 to 15 ft. in height, and, as far as I can recollect, not one of them died, although during the hot sunshine of each day, for some considerable time, the leading as well as the other young shoots hung down quite limp; but the trees were carefully mulched and syringed every evening, and the shoots were always observed to be quite erect in the mornings. All the trees succeeded equally well with others which were transplanted during the following November. Still the month of August can hardly be recommended as the best season for removing coniferous trees, if for no other reason than that each tree required at least three times the amount of labour that would have been necessary if the operation had been delayed until later in the year. It may, I think, be fairly assumed that the best time to transplant deciduous trees and shrubs is as soon as the leaves have fallen, though it may not always be necessary to wait until the middle of October, between which time and the end of November may also be considered as the best for the transplantation of evergreens of all sorts, their season of growth being then completed, their excitability

exhausted; and they are, as nearly as possible, in a condition of rest, with the demand upon their roots at a minimum. To the opinions already expressed, as to the most suitable season for performing the operation of transplantation, a few words may be added. At whatever season this is effected, it is of importance that the roots of the plants should be exposed for as short a time as possible to the drying influences of sun and wind. This is more particularly necessary when the operation is performed late in spring. It is also incumbent to preserve as many of the fibres as possible, and to accomplish this it is necessary to surround the stem of the plant about to be operated upon by a trench, at a distance from the stem of the plant corresponding to its dimensions, carefully using a fork for the purpose of reducing the ball of earth to the dimensions necessary to enable it to be removed to its destination, and at the same time to preserve as many of the fibrous roots as possible. When it is found necessary to amputate large roots, this should be done with a sharp knife, cutting from the underside, as such wounds will readily heal, the same as in the case of a cutting, and will, in like manner rapidly produce a redundancy of healthy young fibres. In all cases, where the specimens to be moved are of considerable size, the employment of one of the many mechanical contrivances (such as Barron's transplanting machine) will be advisable, and, before placing the plant in its intended position, the soil under and around it should previously have been trenched or well loosened up. It is seldom advisable to dig out a pit or hole for the reception of the roots, more especially if the plant be of considerable size, when it should merely be placed upon the surface of the soil, or but slightly under it, the roots carefully spread out, and covered with a portion of light rich soil. Roots have a natural tendency to grow downwards, and it is obviously more to their advantage to have good or surface soil to grow into than to be placed in contact with the subsoil, which is generally the case when the roots of plants are placed in pits or holes. Before finishing the operation of planting, means should be taken to steady the plants by means of a few rough strong stakes driven firmly into the soil, close to the ball of earth containing the roots. The heads of these stakes should be upon a level with the upper surface of this ball, and to them should be securely nailed the ends of two or more rails, which should cross and press upon the upper surface of the ball, and this will generally be found to be all that will be required; but, should that support not be sufficient, recourse should be had to guy ropes; avoid, if possible, the placing of stakes close to the stems of trees, which are very likely to injure the bark. Enough earth should now be placed over and around the roots to form a basin, slightly exceeding in diameter the extent of the roots, and into this should be dashed a sufficiency of water, which will have the effect of thoroughly embedding the roots and fibres in the soil; and, when the water has been absorbed and the soil become somewhat dry, the re-planting may be completed. When this is done, the plant will appear to stand upon a slight mound or elevation, which will enhance its appearance, as well as be an advantage to it in other respects, more especially should the situation in which it has been placed be in any degree damp, or the soil of a retentive nature.

P. GRIEVE.

BERRY-BEARING AUCUBAS.

I WILLINGLY comply with "W. D.'s" request. I budded my female Aucubas in the month of August in precisely the same manner as I bud my Roses, choosing a vigorous shoot of the second or third year in which to insert the bud. I cannot inform "W. D." as to the best season for grafting the Aucuba, for the grafts I inserted at the same period did not grow; but I should say that now, or even earlier than this, would be the most likely season to succeed: doubtless some of your readers could supply some information upon this point; nearly all the buds I inserted grew. As I have frequently heard it remarked that it is difficult to get the Aucuba seed to grow, it may be useful to my brother amateurs to tell them how it can be easily done. First gather the berries as soon as they turn red, and sow immediately as follows:—Place a frame, single or two-light, according to the number of berries desired to sow, in a sunny aspect upon a good rich soil; make a compost 9 in. thick, consisting of equal parts of peat, sandy loam, and leaf-mould; press it down level, and strew the berries evenly over its surface about 3 in. apart, and

cover them with 2 or 3 in. of the same compost; keep the lights off during the summer, and be careful to water whenever dry. The young plants will commence to make their appearance about the beginning of October, and will continue to come up all through the winter; therefore, about the end of September, if the weather become cold, the lights must be put over them and the frost kept out by means of matting or straw, but the covering should be removed to admit sun and light in mild weather. As the young plants will require slight protection for a year or two, they should either be allowed to remain in the frame or be potted, so that they could be placed in a pit or cool house on the approach of winter; for, if planted out before their third spring, they are liable to perish, if the winter prove severe, or, what is more trying, alternating frosts and thaws.

Stoke Newington.

J. DENNY.

The Natural Age of Fruit Trees.—It seems to be the common belief that there is no limit to the natural age of Apple trees. But this is certainly a mistake. We all know that the Peach tree usually fails to be profitable at 12 to 15 years of age, and the Cherry and Plum average only 20 to 30 years; the Pear, in favourable circumstances, 40 to 50 years—in rare cases a much longer time; so, also, the Apple tree has its natural limit, and although, like man's life, the duration of the period of health and vigour varies greatly, according to constitution, nurture, climate, &c., its approaching termination is clearly indicated by signs of debility and disease. On very deep and favourable soils, and where the trees are not damaged by severity of climate, Apple orchards are occasionally found bearing fair crops of fruit at 80 to 100 years of age, but these are nearly as rare as for their owners to live so long. Very few soils are of the best kind for an orchard, and everywhere our climate is either too warm or at times too cold for the best health of the trees. Injury by severe cold blackening all the wood, I am convinced is a very common cause of the premature failure of orchards; but starvation, in consequence of exhaustion of the soil, is still more common, and this is a more difficult matter to remedy than most people suppose, especially when trees have attained full-bearing size.—"Cultivator."

Flowering-time of Willows.—Palm Sunday and Willows are quite orthodox; but I was surprised, when making my notes on Christmas Day, to find *Salix violacea* with catkins. Writing to ask Mr. Scaling if this were unusual, he answers that with him at Nottingham, "*S. violacea* showed catkins on the 28th of October, *S. corulea* on the 18th of November, *S. daphnoides* on the 20th of December, *S. Caprea* on the 25th of that month, and *S. nervosa* and *S. purpurea* on the 6th of January. In November, the *S. angustifolia* still had the catkins hanging belonging to the season 1875, and the two first-named on this list had shown the coming season of bloom, thus bridging over the entire year." The same can be said of hardy Heaths, I think. Is there a third family of plants as numerous, and, at the same time as varied in its seasons of flowering? I counted only eighteen plants in flower, including the Willow this Christmas, while in 1874 forty-five were in bloom. So much for the frost and snow in November.—F. J. HORE, *Wardie Lodge, Edinburgh*.

Curious Movement of Fir Leaves.—M. Chatin has lately called attention in the French Academy to some curious periodic movements in the leaves of *Abies Nordmanniana*, which are whitish on the lower and dark green on the upper surface. If the tree be observed early in the morning, or about sunset, the *ensemble* of the foliage seems uniformly whitish; whereas, in the course of the day, the green tint seems very general. This is found to result from an alteration in the position of the leaves, so that they present, now their upper, now their under surface to the observer, and a diurnal position can thus be distinguished from a nocturnal one. M. Chatin has been studying these movements, and promises some further details regarding them shortly.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

To Prevent the Bleeding of Trees (H.).—There is, we believe, nothing better than Stockholm tar: a little ocre or umber gives it more substance. Thomson's *Styptic* answers well.

***Arancaria imbricata*, Fruiting (Sondes).**—This noble tree has borne comes and perfect seeds in various situations in the United Kingdom. Seedlings from English-grown fruits were raised many years ago by Mr. Barnes at Bicton.

Growth of Roots.—A singular instance of root-growth is reported from France. An Elm tree, standing over Fontainebleau sandstone, forced its rootlets down so that they perforated the rock, leaving in it a perfect impression of their form. It is supposed that the cement which holds the grains of the rock together was dissolved by carbonic acid given off by the roots of the tree. This last statement is, we should say, doubtful, and not necessary to an understanding of the fact. Similar instances are common enough.

PLATE VI.

CALOCHORTUS VENUSTUS.

Drawn by Mrs. DUFFIELD.

The beautiful plant which forms the subject of our illustration this week is from a drawing, by Mrs. Duffield, of a plant that flowered in Mr. G. F. Wilson's garden, at Weybridge. It has been most faithfully and delicately re-produced for us by Mr. Brand. Being thus enabled to fairly represent the beauty of one species, we publish also descriptions of the whole family as now known. These may serve to show what a full store of beauty is possessed by this almost neglected genus, and may also be useful for reference in the future.

History and Distribution of the Genus.

This lovely Liliaceous genus, of which we are now able to give descriptions of more than twenty distinct species, besides a number of varieties, was established by Pursh in his "Flora Boreali-Americana" (1814), for a single species, *C. elegans*, found at the Head Waters of the Koskoosky, in California. This handsome species, as may be seen on reference to the description of it further on, has since been found by several different collectors, and by Douglas as far north as British Columbia. In 1815 the seventh volume of Humboldt, Bonpland, and Kunth's great work, the "Nova Genera," appeared, containing figures of two additional species, referred to the genus *Fritillaria*. These are Mexican species, *C. purpureus* and *C. flavus*, growing at an elevation of between 6000 and 7000 feet, near Patzcuaro, Valladolid, &c. They are described in the first volume of the work quoted, where it is stated that they grow in dry sunny places, a fact worth remembering by the cultivator. The unfortunate David Douglas furnished the next link in the history of the genus; indeed, he discovered, on his different journeys in California and British Columbia, nearly half of the species known at the present time. The first batch sent home by him included *C. macrocarpus* and the yet more beautiful *C. nitida*. These species were probably received in 1825, as we find a paper relating to them by Douglas of that date, in the seventh volume of the "Transactions of the Horticultural Society," accompanied by coloured plates of both species. *C. macrocarpus* is there said to grow in undulating, dry, barren ground, around the Great Falls of the Columbia River, and on the summit of the low hills between them and the Grand Rapids, 200 miles from the ocean. They were successfully raised in the Society's Gardens, and are stated to be quite hardy, as no doubt they are, being both natives of the northern limits of the genus. The next batch sent by Douglas was still more important, for it included *C. splendens paniculatus*, *pulchellus*, and the exquisitely beautiful *C. venustus*, of which we give a portrait to-day. These were raised from seed in the Horticultural Gardens, between 1831 and 1833, and Mr. Bentham described them in the first volume of the new series of the Society's "Transactions." About the same period, or shortly afterwards, figures of them, and several other species, appeared in the "Botanical Register" and Sweet's "Flower Garden," references to which will be found in the descriptions of the several species below, translated from Mr. J. G. Baker's paper, "Revision of the Genera and Species of the Tulipa," in the seventh volume of "The Journal of the Linnean Society." We have pleasure in adding that it is with Mr. Baker's full approval that we take this opportunity of placing this portion of his valuable paper before a more numerous class of readers. Not to weary our readers with too much detail on the history of the introduction of the species, we may at once say that those introduced by Douglas seem to have disappeared very quickly from our gardens; and it is only within the last few years that they have been re-introduced by M. Roezler and others, together with several additional new species and varieties. There is no doubt that they will enjoy a much longer term of favour this time, as there is a growing taste for plants of this class; and we believe, judging from the known variability in the colouring of some species, and especially for the great variety of colours exhibited by the different species, that when the skill of the hybridiser has been exercised upon them, the results will be as satisfactory as in the case of the Tulip. The only deviation from Mr. Baker's

paper is that the variety *citrinus* of *C. venustus* has since been raised to the rank of a species from an examination of living specimens. Of the twenty-two species at present known, thirteen are, or have been, in cultivation. As it is the hardier species that are the most desirable for cultivation, British Columbia and Oregon should be visited for additional species. *C. apiculatus* and *Lyallii*, collected by Dr. Lyall at a considerable elevation in the former country, are not yet in cultivation; and doubtless other species would reward the explorer. The geographical area of the genus extends from about 15° to 50° North latitude, from Mexico, through New Mexico, California, Utah, and Oregon, to British Columbia. One species, *C. elegans*, is reported from Missouri and Oregon (Geyer), otherwise they appear to be confined to the western mountain ranges of North America. From their great range of latitude, it will be understood that the species are not all equally hardy, for, although the Mexican species are found at a considerable elevation, as indicated above, so are some of the more northerly ones; *C. Lyallii*, for instance, is found at an elevation of 8800 feet in the mountains of British Columbia.

Culture.

All the species of *Calochortus* are bulbous, and the bulbs of most of them are small as compared to those of Tulips, rarely, so far as we know, attaining an inch in thickness, and usually not more than half-an-inch. With the exception of *C. Hartwegii*, *purpureus*, and *flavus*, all of them have bulbs with a membranous coat; in those named the coat is fibrous. The stem is usually slender, and the nature of the whole plant seems to indicate that it loves a sunny, well-drained situation. All the information we have been able to collect respecting the native habitats of different species confirms this view, as do also the accounts of the conditions under which they flourished in the horticultural and other gardens. Mr. A. J. Perry, of Tottenham, who is raising them on a large scale, has kindly communicated his experience of their culture. It should be mentioned here, however, that they all flower in the summer and early autumn. Mr. Perry would recommend persons who possess a suitable situation—that is, rock-work, or a well-drained, warm border—to allow the bulbs to remain undisturbed in the ground, as they throw much finer flowers. Planted well up on rock-work, where they were dry in winter and sufficiently moist in summer to do without watering, they made vigorous growth, and flowered freely. The principal requirement is, doubtless, protection from wet. For ordinary beds and borders it is expedient to lift the bulbs and store them until they begin to push. For pot-culture, a fibrous loam, with a little leaf-mould, and plenty of silver sand, has been found to answer admirably. In short, although rather delicate, these attractive plants will succeed very well, if the precautions indicated be taken; and they will certainly amply repay for the little extra trouble they may exact.

Affinities of the Genus.

As here constituted, the genus *Calochortus* is one of the most distinct of the family to which it belongs, and it differs from the other five genera of its tribe, *Lilium*, *Fritillaria*, *Tulipa*, *Erythronium*, and *Lloydia*, in the outer perianth segments being different from the inner or like sepals, as in the *Commelineae*, and in the capsule splitting between the partitions of the cells, not through the back of the cells. Many of the species have open, funnel-shaped, erect flowers, like *C. venustus*; but there are others with nearly globular, drooping flowers, in which the perianth segments are incurved at the tips. The latter approach some of the species of *Fritillaria*, and, as already mentioned, some of them were formerly referred to that genus. Sweet established the genus *Cyclobothra* for some of the species bearing this character, but other species, intermediate in character have been discovered. Taken as a whole, it is a very natural genus, easily distinguished by the characters given, coupled with the more or less bearded petals, on the face of each of which there is a more or less distinct glandular pit.

Key to the Species.

Sub-genus I. *Macrodenus*.—Bulbs, with a membranous tunic; petals, with a deep pit; capsule, oblong.
 Perianth, when open, globose, nodding.
 Petals, yellow 1. *pulchellus*.

Petals, white	2. <i>albus</i> .
Perianth, when open, funnel-shaped, erect.	
Petals, obovate-cuneate, rounded at the top.	
Petals, yellow	3. <i>Benthami</i> .
Petals, pale lilac-yellow.	
Anthers, acute	4. <i>cleagns</i> .
Anthers, remarkably acuminate	5. <i>apiculatus</i> .
Petals, ovate-oblong, pointed	6. <i>Lyalli</i> .

Sub-genus II. Platycarpus.—Bulb, with a membranous tunic; petals, with a small pit; capsule, oblong.

Petals, golden-yellow	7. <i>areus</i> .
Petals, straw-coloured	8. <i>Nuttallii</i> .
Petals, lilac or purple.	
Stem, always one-flowered	9. <i>uniflorus</i> .
Stem, several flowered.	
Sepals, distinctly spotted above	10. <i>flexuosus</i> .
Sepals, without spots.	
Flowers, small; anthers small	11. <i>lilacinus</i> .
Flowers, large; anthers, large	12. <i>nitidus</i> .

Sub-genus III. Cyclobothra.—Bulbs, with a fibrous tunic; petals, with a small pit; capsule, narrow.

Outer perianth-segments similar to the inner; scarcely sepaloïd	13. <i>Hartwegii</i> .
Outer perianth-segments distinctly sepaloïd.	
Petals, purple	14. <i>purpureus</i> .
Petals, yellow	15. <i>javus</i> .

Sub-genus IV. Mariposa (*Calochortus* of Kunth).—Bulbs, with a membranous tunic; petals, with a small pit; capsule, narrow.

Petals, orange yellow	16. <i>luteus</i> .
Petals, lemon-yellow	17. <i>citrinus</i> .
Petals, deep lilac.	
Petals, distinctly cuspidate	18. <i>macrocarpus</i> .
Petals, not all or very slightly cuspidate	19. <i>splendens</i> .
Petals, scarcely bearded	20. <i>venustus</i> .
Petals, without any central spot, and densely bearded	21. <i>Gunnisoni</i> .
Petals, white, with a purplish bearded spot	22. <i>Leichtlinii</i> .

Descriptions of the Sub-genera and Species.

Sub-genus I.—Macrodemus, Baker (*Calochortus*, Pursh, not of Kunth; *Cyclobothra*, Bentham and Lindley in part, not of Sweet).—Bulb with a membranous tunic; leaves without bulblets in their axils; sepals without spots; petals with a deep pit; capsule oblong with deep acute angles; fruiting pedicels bent downwards.

1. *C. pulchellus* (*Cyclobothra pulchella*, Trans. Hort. Soc., new series, vol. 1., t. 14, fig. 1; Bot. Reg., t. 1662).—Bulb, ovoid, with a membranous tunic, $\frac{1}{2}$ to $\frac{3}{4}$ in. thick; stem, 1 to 1 $\frac{1}{2}$ ft. high, with six to twelve flower-heads, deeply forked, branches spreading; leaves, one or two below the forks, moderately firm, 6 to 12 in. long, and $\frac{1}{2}$ to 1 in. broad near the base; bracts, leafy, linear, acuminate, 1 to 4 in. long; flowers, nodding, deep yellow; sepals, oblong-lanceolate, acute, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, not spotted; petals, broadly oblong, 1 to 1 $\frac{1}{4}$ in. long, somewhat obtuse, with a deep glandular pit, bearded with yellow hairs on the margin and the lower half of the face; anthers, oblong, obtuse, 2 lines long, nearly as long as the filaments; capsule, oblong, 1 to 1 $\frac{1}{4}$ in. long, deeply angular. California: discovered by Douglas, and since found by Lobb and others. Raised in the Horticultural Society's garden from seeds sent home by Douglas between 1831 and 1833.

2. *C. albus* (*Cyclobothra alba*, Benth., Trans. Hort. Soc., new series, vol. 1., t. 14, fig. 3, and Bot. Reg., t. 1661).—Bulb, ovoid, $\frac{1}{2}$ to $\frac{3}{4}$ in. thick, with a membranous tunic; stem, 1 to 2 $\frac{1}{2}$ ft. high, with three to twelve heads of flowers deeply forked, with spreading branches; leaves, one or two below each fork, flat, linear, moderately firm, 6 to 12 in. long by $\frac{1}{2}$ to $\frac{3}{4}$ in. broad; bracts, leafy, linear, acuminate, 2 to 6 in. long; flowers, globose, white, nodding; sepals, oblong-lanceolate, acute, without spots, $\frac{3}{4}$ to 1 in. long; petals, obovate-oblong, obtuse, 1 $\frac{1}{4}$ to 1 $\frac{1}{2}$ in. long, bearded with white hairs on the margin, and sparsely on the lower half of the face, and furnished with a large glandular pit; anthers, narrow, oblong, sub-acute, about one-third as long as the filaments; capsule, broadly oblong, 1 to 1 $\frac{1}{4}$ in. long, membranous, with deep, sharp angles. California: discovered by Douglas, and since found by Bigelow and other collectors. It was raised and flowered in the Horticultural Society's gardens from seeds sent home by Douglas between 1831 and 1833.

C. albus var. paniculatus, described by Lindley in the Bot. Reg., under plate 1662, as *Cyclobothra paniculata*, is dwarfier than the type, with narrower leaves and smaller flowers. It is also a native of California, and was first discovered by Douglas.

3. *C. Benthami* (*C. nitidus* of Wood, not of Douglas, *Cyclobothra elegans var. lutea*, Bentham, Plant. Hartw., C. monophylla).—Bulb, ovoid, 6 to 8 lines thick, tunic membranous; stem, 3 to 6 in. high, with 3 to 6 heads of flowers; leaves, one or two, the lower larger exceeding the corymb, linear, 6 to 9 in. long, 3 to 5 lines broad, acuminate; bracts, linear, leafy, 1 to 3 in. long; flowers, erect, funnel-shaped when expanded; sepals, oblong-lanceolate, acute, without spots, yellow and green, 6 to 9 lines long; petals, clear yellow, of the same length as the sepals, somewhat obtuse, covered with a yellow beard all over the face and margin; anthers, lanceolate, acute, 1 $\frac{1}{2}$ lines long, a little shorter than the yellow filaments; fruiting pedicels remarkably curved; capsule, oblong, obtuse, 6 to 9 lines long, with deep acute angles. California: discovered by Hartweg, and not yet, so far as we know, in cultivation.

The variety *cornutus* of Wood has solitary flowers, and long acuminate sepals exceeding the petals.

4. *C. elegans* (Bot. Mag., t. 5976; *Cyclobothra elegans*, Bot. Reg., under plate 1661; *C. corulea*, Kellogg).—Bulb, narrow, ovoid, 5 to 6 lines thick, tunic membranous; stem, slender, 3 to 6 in. high, with three to six heads of flowers, arranged in an umbellate manner; leaf, solitary, 6 to 9 in. long, by 3 or 4 lines broad; bracts, leafy, linear, or lanceolate, 1 to 3 in. long; flowers, erect, and broadly funnel-shaped when expanded; sepals, green, lanceolate, acute, 6 to 8 lines long; petals, obovate-cuneate, 9 to 12 lines long, obtuse, or furnished with a small cusp, white or pale lilac, with a deep glandular pit, bearded with pale hairs on the margin and face, especially around the glandular pit; anthers, acute, 3 to 3 lines long, about half the length of the filaments; 9 to 12 fruiting pedicels, remarkably deflexed; capsule, oblong, 9 to 12 lines long, with three prominent sharp angles. First discovered by Hartweg in California, and subsequently in Missouri and Oregon by Geyer and Spalding, and in British Columbia by Douglas and Hinds.

Mr. Baker considers the following form varieties of *C. elegans*:—*C. Tolmiei*, collected by Tolmie on the banks of the Wallamet river, is a stouter variety with larger flowers than the type, and the face of the petals is bearded nearly all over; *C. Maveanus* (Bot. Mag., t. 5976), discovered by Lobb in California, and since raised in Mr. Max Leichtlin's garden at Karlsruhe, is a dwarf hairy variety, in which the whole face of the petals is densely bearded; *C. Lobbii*, Oregon, Lobb, is similar to *C. Tolmiei*, but having remarkably apiculate anthers; and, finally, *C. subclavatus* is a smaller-flowered form, bearded only at the top of the glandular pit. The typical form was introduced in 1826.

The plant recently figured in the "Gartenflora," as a new species, under the name of *C. glaucus*, should be referred here. Indeed it is the ordinary form of *C. elegans*.

5. *C. apiculatus*.—Bulb, ovoid, with a membranous tunic; stem 1 to 1 $\frac{1}{2}$ ft. high; one to nine headed; leaf, solitary, flat, linear, 6 to 12 in. long by 3 to 9 lines broad; bracts, linear, acuminate, 1 to 3 in. long; flower, broadly funnel-shaped, and erect when open; sepals, lanceolate, broadly obovate, obtuse, 1 in. to 9 lines long; petals, straw-coloured, broadly oblong, 1 in. long, with a distinct glandular pit; pit, densely bearded; whilst the remainder of the face and margin of the petals are furnished with only a few scattered hairs; anthers, straw-coloured, 4 lines long, very acuminate, equalling the filaments; fruiting pedicels, remarkably drooping; capsule, 12 to 15 lines long, narrow, oblong. A native of the mountains of British Columbia: discovered by Dr. Lyall. Perhaps only a fine variety of *C. elegans*. Not yet in cultivation.

6. *Lyalli*.—Bulb, with a membranous tunic; stem, 6 in. high, with two or three flower-heads; leaves, solitary, linear, flat, 5 to 6 in. long by 3 to 4 lines broad; bracts, linear, acuminate, 6 to 9 lines long; flowers, erect and broadly funnel-shaped when 9 expanded; sepals, green and white, lanceolate, acuminate, 6 to 9 lines long; petals, white, slightly exceeding the sepals, ovate-linear, with a deep spot-like glandular pit, and bearded over the entire face and margin; anthers, yellow, somewhat acute, 2 lines long; filaments very little longer; mature capsule not seen. Discovered on the summits of mountains at an altitude of 5800 ft. between the rivers Columbia and Yakima, in British Columbia, by Dr. Lyall. Not in cultivation.

Sub-genus II.—Platycarpus (Baker).—Bulbs, with a membranous tunic; leaves without bulblets in their axils; sepals sometimes faintly spotted on the face; petals furnished with a shallow glandular pit; capsule, oblong, prominently angled; fruiting pedicels erect.

7. *C. aureus*.—Stem, 4 to 6 in. high, with one or two flower-heads. The solitary leaf is radical, linear, and 3 to 4 in. long; bracts, linear, 2 in. long; sepals, oblong or ovate-lanceolate, yellow and green, with purple spots near the base; petals, obovate-

conate, 15 lines long, rich deep yellow, bearded near the base of the glandular pit, and furnished with purple spots near the base of the face; unripe capsule, narrow-oblong. Found growing on sand-rock hills in Southern Utah, by Mrs. E. P. Thomson. Not seen by Mr. Baker, and not yet in our gardens.

8. *C. Nuttallii* (*C. luteus*, Nuttall, not of Douglas).—Bulb, ovoid, with a membranous tunic; stem, 9 to 18 in. high, with one to four flower-heads, arranged in an umbellate manner; leaves, linear, deeply channelled, the lowest 6 to 9 in. long, by 3 to 4 lines broad; bracts, linear, leafy, acuminate, folded, 1 to 1½ in. long; flowers, broadly funnel-shaped, erect; sepals, lanceolate, 6 to 12 lines long, acute, face faintly coloured, and obscurely spotted with purple; petals, 12 to 18 lines long, broadly obovate, cuneate, obtuse, straw-coloured, densely bearded above the base of the glandular pit, and furnished with a smooth spot about mid-way up the face; anthers, bright yellow, obtuse, 3 to 4 lines long, slightly shorter than the filaments; capsule, oblong, 6 to 9 lines long, with deep angles. This species inhabits the Rocky Mountains, and has been collected in Idaho, Montana, Utah, and North California. Nuttall was, we believe, the discoverer. *C. eurycarpus*, of Watson, is probably a more Alpine form of the same species; and *C. parviflorus*, of Nuttall, is a slender variety, with narrow, obovate, sub-acute petals, 6 in. long, with the glandular pit above the middle. Not in cultivation.

9. *C. uniflorus* (not of the Bot. Mag., t. 5804).—Bulb, 3 to 4 lines thick, with a membranous tunic; stem, slender, 3 to 6 in. high; never bearing more than one flower-head; leaves, three or four, linear, the lower one equalling the scape, 2 to 3 lines broad; flower, erect, borne on a naked peduncle, 2 to 5 in. long; sepals, lanceolate, acute, green, destitute of spots, 6 to 7 lines long; petals, 9 to 12 lines long, broadly obovate, cuneate, pale lilac, with an obscure glandular pit, purple above the base, and furnished with long hairs above the glandular pit; anthers, obtuse, 1½ lines long, about a third as long as the filaments; ovary, oblong, capsule not seen. California: collected by Douglas and others.

10. *C. flexuosus*.—Stem, flexuose, branching; bracts, linear-lanceolate, 6 to 15 lines long; sepals, oblong-lanceolate, greenish; the face furnished with deep orange-purple spots; petals, broadly obovate, cuneate, 12 to 15 lines long, purple; claw, deep purple, furnished with an obscure orange-purple glandular pit above the claw, and glandular hairs on the margin; capsule, narrow-oblong. Utah and Arizona: collected by Mrs. E. P. Thomson. Not seen by Mr. Baker, and not in cultivation in this country.

11. *C. ilacinus* (*C. umbellatus*, Kellogg; *C. uniflorus*, Bot. Mag., t. 5804, not of Hooker & Arnott, our number 9).—Bulb, ovoid, with a membranous tunic; stem, 4 to 6 in. high, with three to nine umbellately-arranged flower-heads; pedicels, lengthened; the single sub-radical linear leaf considerably overtops the umbel, being 4 to 6 in. long by 2 to 5 lines broad; bracts, acuminate; leafy, 1½ to 3 in. long; flowers, erect, broadly funnel-shaped; sepals, lanceolate, 6 to 7 lines long, green, tinged with lilac, face without spots; petals, lilac, obovate-cuneate, a little longer than the sepals, furnished with an obscure glandular pit above the claw, slightly bearded around the pit, margin not bearded; anthers obtuse, 1½ lines long, one-third of the length of the filament; pollen, blue; capsule, small, oblong, erect. California: Bigelow, and others. Lobb collected a form with larger flowers, the petals reaching an inch in length and breadth, and the pedicels 4 to 5 in. This variety is not in our gardens.

12. *C. nitidus*, Douglas, not of Wood (*Cyclobothra nitida*, Kunth).—Bulb, not seen; stem, erect, upright, 1½ to 2 ft. high, umbellately, three to four headed; leaves, two or three, ascending, narrow, linear, convolute, lower 6 to 9 in. long by 3 lines broad at the base; bracts, leafy, linear, acuminate; flowers, erect and broadly funnel-shaped when open; sepals, linear, acuminate, 15 to 18 lines long; petals, obovate, spatulate, obtuse, pale lilac, furnished with a distinct densely-bearded glandular pit, and sparsely furnished with long hairs on the face and margin; anthers, yellow, obtuse, 4 lines long, nearly equal in length to the filaments; fruiting pedicels, erect; capsule, oblong, 1 in. long, deeply angled. British Columbia, Douglas; Oregon, Spalding.

Sub-genus III.—*Cyclobothra* (Sweet).—Bulbs, with a fibrous tunic; leaves with bulblets in their axils; face of sepals spotted, and sometimes shaggy; petals, with an indistinct glandular pit; capsule, cylindrical triquetrous. All natives of Mexico.

13. *C. Hartwegii* (*Cyclobothra Hartwegii*).—Bulb, not seen; stem, 18 in. high, flexuose; leaves, five or six, ascending, narrow, linear, glabrous, firm, channelled, 1½ to 2 lines broad, occasionally bearing bulbs in their axils, the lowest 1 ft. long, the upper ones paired, or in threes, 3 to 4 in. long; flowers, one or two; sepals and petals somewhat similar, about 2 in. long, yellow, suffused

with purple, oblong, lanceolate; sepals, a little shorter and more acute than the petals, and, like the latter, furnished with a few hairs above the basal spot; petals, 6 lines broad, with an inconspicuous centre glandular pit; filaments, 6 to 7 lines long; anthers, obtuse, 3 to 4 lines long; ovary, 1 in. long, triquetrous, with small spreading, recurved stigmas; capsule, linear, triquetrous, 3 lines thick. Mexico, in mountain pastures at Aguas Calientes, discovered by Hartweg. This species differs from all others of the genus, and approaches *Fritillaria* in having the outer perianth segments petaloid.

14. *C. purpureus* (*Fritillaria purpurea*, H.B.K., *Cyclobothra purpurea*, Sweet's Fl. Gard., series ii., t. 20, *C. propinqua*, *Calochortus Bonplandianus*).—Bulb, ovoid, with a fibrous tunic; stem, 1½ to 2 ft. high, with one or two flower-heads, sometimes deeply forked; leaves, five or six, firm, ascending, furnished with large bulblets in the axils, lower ones linear, 5 to 6 in. long, upper ones lanceolate, 1 to 2 in. long, by 3 to 4 lines broad; flowers, at first nodding, horizontal at the time of opening, purple; sepals, nearly as long as the petals, oblong-lanceolate, green at the back, glabrous and distinctly spotted below the middle on the face; petals, oblong-lanceolate, 9 to 12 lines long by 3 lines broad, with an obscure glandular pit on the claw, clothed with a purple-yellow beard on the face throughout the middle; filaments, 3 lines long, anthers, obtuse; ovary, cylindrical, triquetrous, 4 to 5 lines long; stigmas spreading and recurved. Mexico: Graham and others. *Cyclobothra grandiflora* is a large-flowered variety in which the sepals especially are longer; *Calochortus fuscus*, of Schultz, is probably a form of this species, with the face of the sepals slightly bearded. This species was in cultivation in this country in 1827. The plant figured in Sweet's Fl. Gard. was from the nursery of Mr. Tate in Sloane Street, where several other species were to be seen, as Mr. Sweet informs us.

15. *C. flavus* (Maunder's Bot., iv., t. 170, *Cyclobothra flava*, *Fritillaria barbata*, *Cyclobothra barbata*, Sweet's Fl. Gard., t. 273, *C. lutea*, Bot. Reg., t. 1663, *Calochortus pallidus*).—Bulb, ovoid, with a hard reticulated fibrous tunic; stem, 1 to 2 ft. high, with one to six flower-heads, slender, fragile, deeply forked, branches ascending; leaves, below the forks from two to three, linear, very acuminate, 9 to 12 in. long; bracts, with small bulblets in their axils—lower ones, linear, acuminate; upper ones, small, lanceolate, somewhat scarious; flowers, at first nodding, yellow; sepals, 8 to 10 in. long, ovate, acute, green on the back, yellow on the face, indistinctly spotted, and furnished with a few scattered bristles; petals, a trifle longer than the sepals, obovate, obtuse, or cuspidate, 4 to 6 lines broad, with an obscure glandular pit on the claw; above the claw and throughout the middle furnished with short purple bristles; filaments, 4 lines long; anthers, yellow, obtuse, half as long; ovary, cylindrical, triquetrous, 4½ to 5 lines long. Mexico: Hartweg and others. Introduced in 1827, and flowered by Mr. Tate, quoted under the last species.

Sub-genus IV.—*Mariposa* (Wood).—Bulbs, with a membranous tunic; leaves, convolute, without bulblets in their axils; sepals, sometimes spotted on the face; petals, with a slight glandular pit at the base; fruiting pedicels, erect; capsule, linear, obtusely three-angled. All the species of this section have very showy flowers, and are very closely allied.

16. *C. luteus* (Bot. Reg., t. 1567; Paxton's Mag., t. 221).—Bulb, ovoid, with a membranous tunic, 6 to 9 lines thick; stem, 1 to 1½ ft. high, flexuose, with one to four flower-heads; leaves, three or four, narrow, linear, glaucous, channelled, 6 to 12 in. long; bracts, leafy, linear, acuminate, 1 to 2 in. long; sepal, lanceolate, acute, or acuminate, yellow-green, 9 to 15 lines long; face with yellow spots and black dots; petals, deep orange, obovate, cuneate, truncate, 12 to 18 lines long and broad, furnished with an indistinct, densely-bearded, glandular pit above the claw, nearly naked upwards, often with a zone of rich brown dots, and a central blotch; anthers, obtuse, 3 to 4½ lines long; filaments, orange, about the same length; capsule, 12 to 21 lines long by 3 to 4 lines broad, obtusely angled. California: discovered by Douglas, who sent seeds to the Horticultural Society's garden in 1831. *C. Weedii*, of Wood, is a variety of the preceding, with deep orange petals, having no central blotch, and densely bearded all over.

17. *C. citrinus* (Bot. Mag., t. 6200).—Bulb, ovoid, under 1 in. thick, with a membranous tunic; stem, 1½ ft. high, firm, terete, glaucous; three to four flowered; forked low down; leaves, tolerably firm in texture, linear, glaucous, those from the bulb 6 in. long, those that sustain the branches similar, but smaller; flowers, permanently erect; sepals, 1½ in. long, lanceolate, acuminate, greenish, and naked on the back, yellow on the face, with a small hairy brown spot near the base; petals, round-cuneate 2 in. broad and deep, rounded, with a cusp on the outer border

bright lemon-yellow, the claw naked, above the claw is a round conical hairy yellow spot, with a purple border, the rest of the face is without any zone or blotch, but covered with spreading purple gland-tipped bristly hairs; stamens, half as long as the petals; filaments, erect, lanceolate; anthers, cylindrical, pale purplish brown, apiculate, diverging, 6 to 8 lines long; pollen, pale brown; ovary, clavate, under 1 in. long; stigmas, short, falcate. British Columbia, Rocky Mountains, and California. This is a new species, quite recently figured in the Bot. Mag. from specimens grown by Mr. G. F. Wilson, Weybridge. It is included in Mr. Baker's "Revision of the Tulip," as a variety of *C. venustus*.

18. C. macrocarpus (Trans. Hort. Soc., Vol. VII., t. 8; Bot. Reg., t. 1152).—Bulb, ovoid, with a membranous tunic, 9 to 15 lines thick; stem, firm in texture, flexuose, 1½ to 2 ft. high, with two to six flower-heads; leaves, three or four, narrow, linear, convolute, lower ones 6 to 9 in. long; bracts, firm in texture, convolute, 1 to 4 in. long; sepals, lanceolate, green, spotless, 15 to 24 lines long; broadly scarious at the margin; petals, about the same length as the sepals, deep lilac, obovate, distinctly cuspidate, claw furnished with a scanty beard around the obscure glandular pit; anthers, somewhat obtuse, 5 to 6 lines long, equalling the lilac filaments; capsule, linear, obtusely angled, 2 to 3 in. long, 3 to 4 lines thick. British Columbia. Sent home by Douglas in 1826, and flowered in the Horticultural Gardens in 1827. The figure in the Bot. Reg. represents the flowers about 5 in. across, the sepals considerably exceeding the petals. Geyer collected a variety with redder-coloured flowers.

19. C. splendens (Bot. Reg., t. 1676).—Bulb, ovoid, with a membranous tunic; stem, flexuose, 1½ to 2 ft. high, with three to five flower-heads; leaves, three or four, narrow, linear, convolute, 6 to 9 in. long; bracts, linear, acuminate, 2 to 3 in. long; sepals, lanceolate, green, spotless, 12 to 18 lines long; petals, deep lilac, 18 to 24 lines long, and broad obovate-cuneate, rounded on the outer margin, or slightly cuspidate, of the same colour in the middle, or occasionally with reddish spots, the third lower one furnished with a purple beard around the glandular pit; anthers, somewhat acute, 5 to 6 lines long; filaments of about the same length; capsule, linear, triquetrous, 1½ to 2 in. long, 3 to 4 lines thick. California: discovered and introduced by Douglas.

20. C. venustus (Trans. Hort. Soc., new series, i., t. 15, fig. 3; Bot. Reg., t. 1669).—Bulb, ovoid, with a membranous tunic, 6 to 9 lines thick; stem, flexuose, 1 to 2 ft. high, with two to six flower-heads; leaves, three or four, narrow, linear, convolute; bracts, linear, leafy, 2 to 4 in. long; sepals, lanceolate, 12 to 18 lines long, face sometimes distinctly spotted; petals, broadly obovate-cuneate, rounded on the outer margin, white or pale lilac, of the same colour in the centre, or spotted with orange-purple; claw, with an obscure bearded, glandular pit, and a few hairs and red-brown spots above the pit; anthers, obtuse, 3 lines long, nearly as long as the filaments; capsule, linear, triquetrous, 15 to 18 lines long, 3 to 4 lines thick, slightly angled. California: discovered and introduced by Douglas.

21. C. Gunnisoni.—Bulb, ovoid, with a membranous tunic; stem, firm in texture, 1 to 1½ ft. high, with one to four flower-heads; leaves, three or four, narrow, linear, channelled, lower ones 6 to 9 in. long; bracts, linear, leafy; sepals, lanceolate, acuminate, 12 to 15 lines long, green, face scarcely spotted; petals, obovate-cuneate, 15 to 18 lines long and broad; rounded on the outer margin or slightly cuspidate, pale lilac or white, without spots in the centre, the third lower one with a deeper lilac zone and densely bearded, and furnished with a bearded glandular pit; anthers, acute, 3 to 4 lines long, as are also the filaments; ovary, cylindrical, triquetrous. Rocky Mountains (Colorado and Utah): Geyer, Gunnison, and others.

22. C. Leichlinii (Bot. Mag., t. 5862).—Bulb, small, ovoid, tunic, membranous; stem, 5 to 6 in. high, slender, flexuose, with one to three flower-heads; leaves, three or four, narrow, linear, convolute, 1½ lines broad; bracts, leafy, 1 to 2 in. long; sepals, lanceolate, green, 12 to 15 lines long; petals, obovate-cuneate, 13 to 21 lines long and broad, slightly cuspidate at the apex, white; claw, with a purple blotch above, and bearded around the obscure glandular pit; anthers, yellow, obtuse, 3 lines long, ovary, cylindrical, triquetrous. On the Sierra Nevada, California: detected and sent home by Roehl.

There is another species in cultivation, under the name of *C. Roezii*, which has not yet been fully described, and the flowers of which we have not seen. According to M. Roehl, who introduced it, it grows about 18 in. high, bearing four to eight flowers of a lovely Prussian blue, with a small purple blotch at the base of each petal. The flowers are even larger than those of *C. venustus*, nearly circular, and lasting a considerable time.

uniflorus (Bot. Mag.)	11		

W. B. HEMSLEY.

GROWTH WITHOUT LIGHT.

THE presence of strong light in the early stages of growth seems to have a retarding influence upon some plants. I have known instances where the Lily of the Valley when forced in pots—especially imported clumps—positively refused to grow under strong light in a warm house, yet, when moved to a dark Mushroom room, or covered with Moss or litter to exclude light, the buds started directly. *Dielytra spectabilis*, Lilacs, and many other deciduous plants and shrubs will break more readily in the dark than when exposed to strong light. I once saw an experiment tried in a house containing young pot Vines; they were exceedingly sluggish in starting and the produce was wanted early, and after twisting the canes with a view of liberating the sap, till the tissues fairly cracked without producing any effect, the house was covered with mats for a week night and day, whilst at the same time the requisite temperature with plenty of moisture was kept up; the upshot was they broke strongly and regularly and carried a good crop. Of course where anything is covered up in this way to expedite growth, when the buds are pushing and the sap fairly in circulation, the covering must be removed and light admitted, choosing a dull day if possible for uncovering; as, although growth or elongation in all plants under either natural or artificial conditions takes place mostly in the night, or at least during that period of the twenty-four hours when the sun is absent, still without its consolidating and maturing influence such growth or elongation would be useless for producing fruit, or in most cases flowers either; but as regards the latter there may be a few exceptions, one illustration of which may be furnished by the plan now commonly adopted of forcing Lilacs in the dark for the purpose of obtaining pure white flowers. Anyone accustomed to note the changes that take place in spring must often have been struck by the effect produced by two or three dull warm days, when accompanied, as they often are at that period, by comparatively warm nights. There is something almost magical in the rapid unfolding of the leaves, which is much more noticeable than in bright sunny weather, as such days are often followed by cold frosty nights, which chill the sap and stop growth. In securing the rapid germination of seeds when sown in pots or pans under glass, it is a common practice to place a layer of Moss over the surface of the soil after the seeds are sown, and this has been found materially to hasten their growth. In the same way covering Radishes and other early crops in the open air with straw or mats to exclude light and secure an even state of moisture and temperature has an important influence in the early germination of the seeds. Some may say that the even state of moisture has as much to do with it as the exclusion of light, but whilst that even state of moisture cannot easily be secured without excluding light, I believe, judging from my own observations and experiments, that its exclusion, as far as germination is concerned, is most important.

EDWARD HOBDAV.

Forming Flower-beds in Snow.—A rope is useful for marking out irregular beds, or lines of walk; but I saw, the other day, some beds marked out on Grass in a few minutes on the thin snow. The outline was well shown up by the dark line of Grass, and pegs were at once set, in case of thaw.—F. J. HORG, Warrick Lodge.

THE FLOWER GARDEN.

FAILURE OF COLCHICUMS, &c., THROUGH DEEP-ROOTING.

By JAMES M'NAB, Royal Botanic Garden, Edinburgh.

COLCHICUMS, or Meadow Saffrons, as they are generally called, are very interesting plants, particularly during their flowering season, which ranges, according to circumstances, through the greater part of the months of August and September, as will be seen by the annexed account of their blooming in the rock garden during the past autumn. Some of the same species and varieties, although flowering on other dates (sooner or later) in various parts of the garden are not so punctual. This seeming irregularity, however, depends entirely on soil and situation. Those growing in the rock-garden compartment are all cultivated under the same circumstances as to soil and exposure. I therefore give the order and dates on which they came into bloom :

Aug. 10.—Colchicum autumnale (single pink)	Aug. 26.—Colchicum variegatum Sept. 11.—" autumnale
" 12.—Colchicum autumnale (single white)	" 14.—Colchicum autumnale (double pink)
" 18.—Colchicum crociflorum (double white)	" 18.—Colchicum rubrum
" 20.—" pallidum	
" 23.—" speciosum	

Most of the species are of easy cultivation. Care, however, must be taken not to allow the roots to remain too long in one place, as they are apt to get into dense groups, a condition in which some varieties will not flower, while others produce numerous weakly blossoms from one root, such as the single-flowered pink and white sorts. The double pink variety, however, seems to flower as freely when thus circumstanced, as it does when growing singly. The two species to which I wish more particularly at present to direct attention are *C. speciosum* and *C. rubrum*. The former is one of the most beautiful of the large pink-coloured kinds; but, like the others, it must be occasionally lifted and re-planted, in order to secure good flowering bulbs. On lifting some plants of it lately, after having been two years in the ground, the flowers not being equal in size to those produced the year after planting, the bulbs were found to have a number of young bulblets firmly clustered round the old ones, all of which were removed and planted separately. The *Colchicum rubrum* is another very interesting dwarf dark purplish species, but one which seems to flower very sparingly. In two stone compartments of the rock garden four bulbs of this variety were planted four years ago about 4 or 5 in. under the surface; at first the original bulbs flowered well, but were observed to be dwindling off every season, until last autumn only one flower was produced in each compartment, the supposition being that the roots had all decayed. These compartments were recently turned out, in order to examine the state of the roots, when instead of being 4 or 5 in. under the surface, they were mostly found to be from 8 to 10 in., and in a compact mass, chiefly small tubers thickly coating the bottom of each compartment, but too deep to flower properly, or even to produce leaves. All were lifted, separated, and again planted near the surface. It seems to be characteristic of this variety to work down into the soil, when neither flowers nor leaves can be developed. In some of the London nurseries visited last autumn I observed large portions of beds originally planted with this variety apparently empty, a few flowers only being visible. On these beds the roots had doubtless worked down too deep for flowering. Of these recently lifted here, I had some planted in stone compartments having artificial bottoms formed of porous brick placed about 4 or 5 in. below the surface, in order to keep the roots from working down, and thus give them a better chance of becoming ripened for flowering, which they could not possibly be at the depth at which we found them.

Crocus nudiflorus, *sativus*, *serotinus*, and *speciosus* are all autumn-flowering varieties, the bulbs of which have a tendency to get down too deeply into the soil to flower well for any length of time. They therefore require occasional lifting and dividing, otherwise more leaves are produced than flowers. Among the kinds just named *C. speciosus* is one of the most interesting. It does not, however, produce so many leaf-shoots when not lifted as the other autumn-flowering varieties men-

tioned; still, when left too long in the ground without lifting, the flowers become small and less highly coloured than they otherwise would be, and never have the same appearance as those lifted and replanted every two years. It is not an uncommon practice to lift the roots after the flowering season is over, and keep them dry for a time before re-planting them. This practice may answer very well in England where the roots are more thoroughly ripened before lifting than in Scotland, but I never found any bad effects produced or qualities impaired in the garden here by keeping the roots constantly in the ground, lifting and re-planting them only when found necessary. It does happen that when lifted and kept dry for a time (which certainly is not their natural condition) the roots are apt to become weak, and the flowers diminish in size. The *Iris reticulata* is another very interesting bulbous plant, but, if kept too long in the ground, particularly in one situation, the roots are apt to become leafy, and few flowers are the result. This *Iris* flowers very freely here both in the rock garden and in beds. It is generally lifted and re-planted every two or three years. When lifting is necessary it is generally done as soon as the flowering is over, and while the old leaves and flower-spikes are attached, keeping the larger or flowering roots in rows several inches apart each way, and the smaller ones also in rows close together. A system frequently practised is to lift the roots, and keep them dry for some months before re-planting them. By this treatment I never found them to produce such fine flowering masses as they do when the roots are kept constantly in the ground. By this management the small roots soon work into flowering plants, while, by the lifting and drying system, many of the smaller roots dry up altogether; and if care be not taken to plant the large or flowering roots in proper time they too frequently come up weak, and in some cases rot off altogether, which never happens when constantly in the ground.

SPRING-SOWN PRIMROSES.

My first flowers of the Primrose were obtained from a batch of seedlings raised from seed sown early last spring. These, when large enough, were pricked out into a shallow box, and placed in a shady situation, where they were allowed to remain throughout the summer, of course being liberally supplied with water. These plants not only maintained their foliage, but produced large robust crowns, whilst all those growing out in the beds lost every leaf. The blooming season of the Primrose, thus well started with the first days of the year, will last over three months, probably longer, as some varieties bloom later than others, and nearly all this year will be later than usual. I think this collection comprises about fifty plants, and, judging by what have already opened, almost fifty diverse hues of colour may fairly be anticipated. This fact forcibly shows the numerous varieties of colouring that the Primrose is assuming, and how lovely might our woods and glades be made if carpeted with myriads of these beautiful spring flowers. Of course, my Primroses are under glass; but, although protection is by no means necessary to their cultivation, there can be no question that thus early in the year the protection afforded by a frame is amply demonstrated by the superb condition of the flowers. In the case of common sorts, which are in abundance, protection is of little moment; but when scarce kinds or a batch of choice seedlings are in question, it would be the height of folly to begrudge a little temporary shelter, especially as the rich colours and beauties of the flowers are rendered so much more perfect and clear. Where the cultivation of the Primrose is a speciality, the devotion to its winter culture in a small frame covered with glass is amply repaid by the extra precocity of the plants, and the singular charms presented by the flowers in all weathers. In houses the plants may contract green fly and a rank growth of leafage, but in a cold frame, and planted near the glass, these defects are not apparent, and, as soon as the bloom is over, the plants may be removed to some shady border where they may find themselves little affected by the summer heat. From seed sown as soon as ripe last summer I have some strong plants that will flower late in the spring, but the majority are too small, although the seed was sown under glass, and it would be better to delay

sowing till another year. Seed sown as soon as ripened usually germinates with considerable irregularity, some of it lying in the soil for months before making growth. It would be, therefore, impossible fairly to decide upon its qualities until after another year's cultivation. Spring-sown seed, on the other hand, usually germinates very evenly, and all the plants so raised will flower the following spring, so that the quality of the bloom is soon made manifest. In addition to a large quantity of selected named kinds now under glass, I intend also to bloom a good batch of selected seedlings of last year to further test their quality, so that, with the two seedling batches already mentioned, I have fair hopes of successfully raising many new and beautiful varieties. Our greatest want now is a good bright yellow; whites we have almost perfect, and sulphur lines the same, but a good golden hue is still wanting. Queen of Yellows, so far, is the best; but it does not exactly realise the idea of a yellow Primrose, either in shape or hue. Deep rich colours are fairly abundant, and from the progeny of the pretty lilac kind, commonly known as *altaica*, some beautiful mauve, violet, and purple tints are being produced. Probably it will soon be said of the common single Primrose, "that the variety and beauty of the flowers are beyond description."

ALEX. DEAN.

Bedfont.

TWO PRETTY COSMOPOLITAN WATER PLANTS.

An American friend of ours recently brought over some plants of the Bog Bean (*Menyanthes trifoliata*), rightly thinking such a pretty plant worthy of cultivation, and not knowing that it was a native of British as well as American bogs. The Bog Bean and Bog Arum, like a number of other plants, had common possession of the two worlds long before the white man had crossed the Atlantic. Both these plants have something more in common, i.e., they are both perfectly hardy, thrive in boggy and muddy places, margins of lakes, mud-banks, &c.; both are dwarf in stature, both have creeping stems that root as they creep, both have distinct and graceful foliage, especially when growing freely in rich ground, and both have beautiful flowers. They are plants which everyone who cares for ornamental marsh and aquatic plants should possess.

The Bog Bean.

The Bog Arum.

British Berry-bearing Climbing Plants.—Will you kindly give me the names of a few British climbing plants that bear conspicuous berries?—A. C. [The most attractive berry-bearing native climber is the Red Bryonia (*Bryonia dioica*), the only cucurbitaceous plant found wild in Britain. It has a large fleshy root-stock, palmately-lobed rough leaves, and small spherical red berries. It should be borne in mind that the sexes are borne on different plants. Next comes the Black Bryonia (*Tamus communis*), also dioecious, which likewise has a fleshy root-stock, twining stems, glossy heart-shaped leaves, and oblong red berries. Both of the foregoing are acrid and somewhat poisonous plants. Then there is the Honeysuckle with small bright crimson berries. The wild Roses are also very showy when in fruit.—W. B. H.]

Anemone fulgens in the Holy Land.—I am glad to see reference made (see p. 79) to this beautiful flower. During my visit to Palestine in the spring of 1874, I saw it in great beauty. The slopes of the valley of Ajalon were densely covered with it, and in the valleys of Hinnon and Kodron, outside the walls of Jerusalem, it was difficult to avoid treading on it. One of the finest sights I ever beheld was on the morning of the 20th of March, on my journey from Bethlehem to Jerusalem. During the night the snow had fallen (an exceedingly rare occurrence) to the depth of some inches. The morning, however, was bright and clear, and the sun's rays having somewhat depressed the snow, the dazzling scarlet Anemone had forced itself through the white sheet, standing erect with its large petals flatly expanded, and no other plant or flower being visible. In some places they lay closely together in nebulous

clusters, while the whole plain, as far as the eye could reach, was thickly dotted over with the bright star-like gems. The scene was indescribably beautiful, and one not easily forgotten.—WM. VALENTINE, *White Abbey, Co. Antrim*.

Wintering Centaurea ragusina out-of-doors.—I take off my cuttings of this in September, and put them in along the base of a north wall, in small beds, consisting of leaf-mould, loam, and sand, with $\frac{1}{2}$ in. of sand on the top. Here they remain all winter, and are never protected except on the appearance of frost, when a hoop, with a mat thrown across, suffices to keep them safe. By lifting a few of the strongest, and potting them in 43-sized pots, using the same compost as above-mentioned, plants may be obtained that will flower during April and May. After potting, place the pots in a cold frame, with a north aspect. I find *Calcarias* to do remarkably well under the same treatment.—J. M'A., *Dublin*.

Nightshades.—Will you favour me with the names of the British Nightshades?—A. C. [The Deadly Nightshade, *Belladonna* or *Dwale* (*Atropa Belladonna*) is an erect branching herb, 2 to 4 ft. high, with glossy black berries; the Woody Nightshade or Bittersweet (*Solanum Dulcamara*), has long trailing or rambling stems, and ovoid, red berries in clusters; and the Enchanter's Nightshade, *Circea lutetiana*, is a slender, shade-loving herb, 1 to 2 ft. high, with a capsular, prickly fruit. *Solanum nigrum* is also sometimes called Nightshade. It is an erect herb, 2 to 3 ft. high, bearing small, spherical, black, red, or yellow berries, according to the variety.—W. B. H.]

Distribution of Rare Alpine Plants.—According to Mr. Rhiner, who has tabulated the species recorded from the different cantons of Switzerland, there are sixty-three peculiar to Valais, forty-eight to Tessin, thirty-five to the Grisons, and fifteen to Vaud, while Lucerne possesses only two, Glarus one, and Uri and Unterwald none, as well as the vast canton of Berne, which stretches almost across Switzerland. De Candolle seeks to connect the greater richness in species with the earlier disappearance of the glaciers of the glacial period, and endeavours to show that the different geological formations and present climatal conditions have had little to do with bringing about these differences in the vegetation. On the other hand, he remarks that under the present state of things the rarer species of the ancient flora of the Italian Alps present the appearance of plants whose dis-

appearance is imminent. The soil is already occupied by plants better adapted to flourish under the actual conditions of climate and soil, and a succession of exceptionally dry seasons, or the too frequent visits of collectors, will cause them to disappear.

The Giant Christmas Rose.—Permit me to say that the scientific name of the large-flowered Christmas Rose so much in discussion of late is the *Helleborus abchasicus* of Robert Brown. It increases as well in autumn, as in early spring, but if increased in autumn the pieces must be left larger; spring, before the fresh leaves are bursting, is a very good time to increase it; the plant may be cut up into very small pieces, each of which, however, should be provided with at least one rootlet; mere eyes without any root at all scarcely succeed. I had no seeds on my plants, but it does produce seeds in continental gardens.—MAX LEICHTLIN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Arundo conspicua.—This fine ornamental plant is not sufficiently known, or it would be more extensively cultivated than it is. Ours were unusually fine last season, one plant having had no fewer than sixty-eight blooming stems, 8 to 9 feet high. It is as beautiful with me as the *Pampas*, though somewhat smaller than the *Pampas* when well grown, and much earlier.—J. B. E.

Orange Trees in the Open Air (B. M.).—These, if in good health when removed from their winter quarters, may be placed out-of-doors in a warm sunny place. A good time to put them out is the end of May, and they are much better if all their growth is made out of doors. A terrace-walk in front of the conservatory is a good place for them.

Violets in Winter and Spring (B. B. A.).—Plant-rooted runners or suckers, in April or early in May in good light soil, a foot apart every way; water well after planting and in dry weather, keeping clear of runners and weeds. There are few situations more suitable for Violets than under fruit trees in an orchard in severe weather; few or no flowers will be obtained, and to obviate this a plantation may be made in cool frames.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Potting Indoor Plants.—Caladiums should now be started; if they have been allowed to rest for some time, they ought to be shaken out of the old soil and re-potted in fresh material; they succeed best in good loam, with a little leaf-mould and some sand added. In preparing soil for these and for all other plants, the quantity of sand used should be regulated by the description of loam or peat employed; when these naturally contain a considerable quantity of sand, it is unnecessary to add as much as where little exists; for, where potting soil is made over-light by the addition of too much sand, it has the effect of reducing its fertility, and, consequently, the growth will be weaker than in the shape of manure be applied, the growth will be weaker than if otherwise would be. In the case, however, of those who have not had an opportunity of ascertaining the proper quantity to use for the different families of plants, it is best to err on the right side by putting enough; there will then be no danger of the soil becoming sour through being too adhesive. It is the more necessary to urge this, as the generality of beginners in the cultivation of pot plants use too little sand. When light, open material, such as dry, shaly, rotten manure or leaf-mould is added, it has a tendency to keep the soil in a porous state; but additions of these are not usually made, except for such plants as are all or partially shaken out every year. When Caladium bulbs get larger than they are required they may be divided, cutting them in halves or in four, with a portion of the crown with buds attached to each division, smaller plants being generally more useful than such as have got over-large. In all cases, before potting these and other stove subjects, put the soil, before using it, near the pipes, or in some place where it will get as warm as the atmosphere of the house in which the plants are to be grown, and immediately they are potted, place them in heat. I have known such plants as these killed by being allowed to stand for a few days in a cold potting shed, the moisture from the cold soil effecting their destruction. The small *C. argyrifolium* is still one of the best, and *C. Belleynei*, *C. Barquinii*, *C. Chantinii*, *C. Wightii*, and *C. bicolor splendens* are all distinct and handsome kinds. A few *Gloxinia splendens* are also now be potted, using soil similar to that for the Caladiums; the upright varieties are at the present time most in fashion, yet some of the drooping sorts are very beautiful, and look quite as well in a cut state. The following are good kinds, viz., the *Czar*, *Alfred de Musset*, *Duke of Edinburgh*, *Panhiere*, *Scarlet Gem*, *James Brand*, *Don Louis de Portugal*, *Magenta Queen*, and *Mr. Thomas Binney*. These are all erect-flowering kinds. The undermentioned are pendent, viz., *Angeline*, *Mogul*, *M. Alphonse*, *delicata*, *Grand Monarch*, *Ne Plus Ultra*, *Bird of Paradise*, *M. Grivet*, and *Mrs. Wm. Bull*. When required to flower early, some *Achimenes* should also now be started. The best plan with these is to procure some seed-pans; place a few crocks in the bottom of them, and over these lay the soil. The latter ought to be quite fine, consisting of ordinary loam sifted, to which one-fourth of leaf-mould and sand should be added. Out of a mixture such as this they can be removed to their blooming pots without breaking their roots. When they have made a couple of inches of growth they will be fit to pot off. All the above plants should be placed in a temperature of 60° or 65° at night, and should be allowed a rise of 6° or 8° during the daytime, giving no more water until they have begun to grow and have formed leaves, than will keep the soil a little moist; for, if too wet at starting, they are liable to rot.

Pits and Frames.—More *Seakale* and *Rhubarb* roots should now be put into these, treating them as recommended for those used for the earliest crop. Give *Rhubarb* in growth plenty of water, for, when well supplied with moisture, it comes much stronger than it otherwise would do. Roots of *Seakale*, that have been forced, should be laid in sand or ashes, out of the reach of frost; and, if there be not a sufficiency of young roots for planting, some of these may be used for that purpose when the time comes for putting them in. It is now time to get together as much fresh stable-manure as will make up a good bed under one or two-light frame for raising *Cucumbers* and similar plants, and also for early *Carrots*, *Potatoes*, and *Radishes*; the manure for such a purpose should, if possible, be mixed with half its bulk of leaves, as a mixture of this kind is sooner ready for use, does not heat so excessively, and retains the heat longer than when manure alone is employed. Material for such beds, whether mixed with leaves or wholly manure, should be well shaken, thrown into a heap, and, if dry, watered. It should then be allowed to remain for five or six days, then turned over again, shaking the whole thoroughly, an operation which should be repeated soon afterwards a second time in a similar manner. In the interval, any repairs, in the shape of broken glass or re-painting that the frames to be used may require, should be done so as to allow of their getting dry before they are put over the bed. Autumn-sown *Lettuces*, in frames, that are intended for planting out later on,

should be examined now, in order to see that the soil does not get too dry; for, although they winter best when the surface of the bed is rather dry than moist, yet they must not be allowed to become over-dry. If it be found that water is needed, let a moderate quantity be given early in the morning, admitting air during the day, so that the top may get dry. Give plenty of air in mild weather to *Lettuces* more advanced in growth, and to *Endive* under cloches or hand-glasses. Take the lights off *Cauliflowers* during the daytime, when dry, whenever the weather is mild. Slugs, if any, should be sought for early in the morning before they have crawled out of sight for the day. In their case destruction is better than prevention, yet a slight dusting with a mixture half soot and half powdered lime will not only keep them in check, but be beneficial to the plants.

Kitchen Garden.—Ground, as it is cleared of winter crops, such as *Turnips*, *Savoy*s, *Cabbages*, or *Brussels Sprouts*, should be manured and dug over, but it is not advisable to clear off all the old stools of these plants unless there is plenty of *Coleworts* and *Curled Greens*, or *Cottager's Kale* to come in for use, as where these are deficient the stumps, if allowed to stand, will furnish a quantity of tender useful sprouts through the spring. A piece of ground should be selected and prepared by moderately deep digging whereon to plant *Horseradish* and *Jerusalem Artichokes*. They ought not, however, to have the best position in the garden either as to soil or situation, but they should by no means be consigned to the out-of-the-way corners in which they are often put. In growing *Horseradish* it is better to follow the practice adopted by the Manchester market gardeners of planting the whipthong-like portions of the roots than the more general system of using the crowns. Under the former method the longest and straightest pieces that can be got of the thickness of an ordinary pencil are put in with a dibble, not straight down as in planting most things, but slanting at about an angle of 45°; the rows should be 2 ft. apart, and the plants 18 in. asunder in the rows. If the soil be well dug and liberally manured, *Horseradish* will grow as large by this method in a single season as it will in two or three by the usual practice of planting the crowns. In the cultivation of *Jerusalem Artichokes* the small tubers only should be planted, keeping the larger ones for use. They should not be put closer than 2 ft. 6 in. betwixt the rows, and 18 in. plant from plant in the row. Make holes with a dibble 5 in. deep, raking the ground afterwards to fill them up. The *Jerusalem Artichoke* likes plenty of manure. The few sunny days that we often get at the beginning of this month frequently induce amateurs who are anxious to keep pace with the season to sow many things that are much better deferred to a little later period. Where there is an unlimited extent of ground it is worth while sowing some things as early as there is a possibility of their succeeding; but, except in the most favoured situations as to soil and climate, it is much better not to put seeds in the ground until the time has arrived that there is enough heat in the soil to at once induce growth and keep them moving on without the check which they inevitably get if severe weather come later on, and which has the effect of not only keeping them back until the later-sown crops are as early, but much more productive. The longer seeds are in the ground before they can make progress, the more they become weakened, and in some cases destroyed altogether. The seeds of many things will be more than usually susceptible to injury from this cause the ensuing spring, from their being indifferently matured through the wet and cold of last summer.

Lawns and Pleasure Grounds.—Where there is any turf laying either for new lawns or croquet grounds, no time should be lost in preparing the ground for its reception, for in all cases after it has been levelled it should be allowed to remain before being turfed until it has been well soaked by the rains; this will cause it to settle, and then whatever inequalities exist can be rectified before the turf is laid down; wherein if it be laid before the settling takes place, it will necessitate its being again disturbed. The same holds good in preparing similar ground for being sown down with grass seeds. Where turf has to be made good on lawns or verges, it should be done at once, so that the Grass may root freely before dry weather in spring sets in.

Conservatories.

With the number of forced plants now coming on there will be no difficulty in making conservatories gay and attractive. An atmosphere just sufficiently warmed by fire-heat, accompanied by a slight movement of air from the ventilators will be the right way to prevent any damp settling on the flowers and disfiguring them. The thick fleshy nature of *Camellia* blooms renders them very liable to injury, if the air of the house be at all damp; if must, therefore, be kept slightly in motion to dispel it. A temperature ranging between 45° and 50° by night, with a slight rise during the day, will be quite warm enough for any plants that ought to be admitted to these structures, as, when the thermometer rises above 50°, the effects are

sure to affect the permanent occupants of the house. Examine the borders in which creepers and other plants are growing to see that they are sufficiently moist to start them properly into growth. If any be found dry, give a thorough soaking with tepid water, and then let them stand till they really require it again. Those gems among conservatory climbers, *Lapageria alba* and *rosea*, can scarcely have too much water while growing and blooming, provided they have the right kind of soil in which to grow and are properly drained. During the winter, however, after the blooming period is over, water should be almost entirely withheld, as then the soil has a chance of getting into a sweet healthy condition before growth re-commences. Where these are getting out of condition, from the soil having become close and inert, a good portion should be removed and be re-placed with lumps of tough fibry peat and loam in the proportion of two-thirds of the former to one of the latter. To this add a good sprinkling of sharp sand, and work the whole, when mixed, well in amongst the roots. In starting young plants, prepare the border by putting in a foot or so of porous red brick for drainage. These should be broken up into moderate-sized pieces, and have rough sods of peat laid over them to prevent them from becoming filled up by the soil washing down during the copious waterings required. Over the drainage, a depth of at least 2 ft. of rough peat and loam will be required, and this should be placed in almost as rough as when out for stacking, when, by throwing some sharp sand amongst it, the body of soil is always kept well open, so that water will pass readily through. The best time for planting or interfering with the roots of *Lapagerias* is just when they are commencing growth, as then they soon lay hold of the soil. The readiest way of increasing these is to layer some of the strong young shoots, as they are very slow in making plants when cuttings are inserted. The *Lapagerias*, unfortunately, become infested with thrip and white scale, and without frequent attention in sponging and cleaning soon become sadly disfigured and injured. Care must, however, be exercised in doing this, as the leaves are very brittle near the footstalk, and, if turned up to get at the under-side, often get injured, if not wholly broken off. Where *Eparis*es and *Heaths* have to be introduced to these structures, they should, if possible, be placed in the coolest part, where they can have plenty of air and be kept well up to the light. *Eparis*es, such as *miniatia*, *m. splendens*, and *grandiflora*, are almost continuous bloomers, and stand heat and a close confined atmosphere much better than the other varieties, and are, therefore, more useful. Keep such things as *Cyclamens* and *Primulas* well up to the light, and water the latter carefully, so as to prevent any lodging in the crowns of the plants. As the double varieties go out of bloom place them in gentle heat on shelves near the glass to start freely into growth before dividing for propagating purposes.

Plants in Rooms.

Select for purposes of this kind such subjects as *Dracenas*, *Solanum capsicastrum*, *Thyracanthus rutilans*, and other soft-wooded plants that can be got up quickly, and are of no great value after blooming. Except in very light positions in windows, and other favourable situations, there are few plants that will stand the close atmosphere of rooms for any length of time without suffering some amount of injury; and, therefore, anything choice should be assigned the best positions, or be kept out altogether. *Dracenas* are, perhaps, the very best for the purpose, as they will stand a deal of ill-usage, and soon right themselves again on being placed in heat and moisture. Their rich-coloured leaves appear to brighten under artificial light, which renders them doubly valuable for room decoration. If these and others having leaves that can be handled remain in long, they should be frequently sponged, as nothing tends so much to keep them in health, or add to their attractive appearance. For table decorations nothing can exceed the beauty of the *Thyracanthus*, with its long strings of gracefully pendent scarlet flowers, drooping from the tips of the plants, and resting on the snow-white cloth. Plants of two years old are best, or such as can be run up with stems at least 2 ft. high, as then the flowers show off to great advantage. No stove-house should be without a few plants of the above, as it is without a rival for table decoration at this season of the year.

Stoves.

Where *Bougainvilles* are grown as roof-climbers planted out, they will now require watching to keep them free of large gross shoots, that are sure to break away from the main stems at this season of the year. These should be cut out directly they show themselves, as they grow at a rapid rate, and, if the plants be allowed to become at all thick with growth, the removal of these gross shoots is attended with some difficulty, on account of the numerous sharp-hooked thorns with which the plant is armed. The two varieties now in general cultivation require very different treatment as to time and manner of pruning, although both may be grown in the same house.

To flower them successfully, it is very necessary that the roots should be under control and restricted to a certain limited space, which must be in proportion to the extent of roof the plants are to cover. They are naturally rampant growers, and when their roots have full freedom to ramble unrestrained, it is very difficult to flower them in anything like the freedom they are capable of. *B. speciosa* is, perhaps, the most valuable of the two, on account of its flowering at this season of the year, and lasting in beauty more or less up till May. Although at one time considered a shy bloomer, it is in reality not so when it has its roots restricted so as to prevent a too exuberant growth that it would be impossible to ripen. This is the only secret of success in flowering this charming plant, and where the aspect of the house is favourable to get plenty of sun, so as to insure hard ripe wood, its flowering annually with the greatest freedom may be counted on with certainty. Any wood that may have been laid in too late to ripen properly, and that is not showing bloom, should be cut out to allow plenty of light to colour the bracts of inflorescence forming on the other shoots. *B. glabra* flowers on the young wood, and the plants should now be thinned out and spurred in to encourage fresh growth and allow room for it. This variety will stand much cooler treatment than *speciosa*, and may with safety be wintered in the temperature of an ordinary greenhouse, if kept dry at the roots. With cool treatment of this kind it loses its leaves, which in heat it retains all through the winter. As a pot plant for spring and summer blooming, *B. glabra* is most valuable, as, by introducing one or two into heat at a time, the flowering season may be greatly prolonged. Before starting them into growth they should be freely thinned out, leaving only the strongest and best-situated shoots for laying-in. As soon as they begin to break shakes them out of the old soil and re-pot in good fibry loam; give but very little water until they get well into leaf, but syringe freely overhead or keep them in a moist atmosphere. *Amaryllises* are among the most useful of stove bulbs when treated so as to get them into bloom during the winter season. For this purpose it is necessary to urge their growth forward to mature and ripen the bulbs. They enjoy strong heat, both bottom and top; and I have always found them grow and flower best when placed on the top of hot-water pipes with only a thin strip of wood to keep the bottoms of the pots from touching them. In the summer they are plunged in bottom-heat in pits or frames, where they are kept well up to the glass and fully exposed to the sun, after which they never fail to flower in the most satisfactory manner. The beautiful, free-blooming, soft, lavender-coloured *Hobecelinium ianthinum* is most valuable at this season, and no plant-stove should be without it. With a little preparatory hardening off it will stand the temperature of the greenhouse or conservatory well, and is therefore doubly valuable on that account. While in the stove it must have abundant supplies of water; but, when removed to a cool temperature, the ball should only be kept just moist. If placed in the greenhouse or conservatory when in bloom, it is one of the most lasting things it is possible to have. *Euphorbia jacquiniiflora*, going out of bloom, should be kept dry at the roots to harden the wood preparatory to cutting back. These and *Poinsettias* can be stored away at the backs of stages, or in any dry place where they can have a temperature of 50°. As there will be young plants of various kinds to pot off and shift on almost daily, a good stock of soil of different descriptions should always be kept under cover, so as to be ready to hand when wanted. Any dirty pots should be soaked in water for a few hours, preparatory to being scrubbed and cleaned, after which they must be allowed to become thoroughly dry before being used. Advantage may always be taken of bad weather to carry out such work as the above, also the making of a good stock of labels, flower sticks, &c., as in few places can time be spared for such purposes after spring sets in.—J. SHEPPARD, *Woolverstone Park*.

Roses.

Roses for forcing purposes are so plentiful now-a-days that sufficient blooms may be had during the winter and early spring months for bouquets and furnishing purposes. To these the beautiful dark Tea Rose, Duchess of Edinburgh, figured the other day in THE GARDEN will prove a welcome addition. The autumn of 1875 was wet and sunless both for pot and out-of-door Roses; and therefore owing to the wood not being well ripened I have found it difficult to get Hybrid Perpetuals to flower this winter, but Tea varieties have been all that could be desired. The best varieties for forcing in December and January—two of the darkest and generally worst months during the whole year for Roses—I have found to be *alba rosea*, a good white shaded with rose, and one which lasts well, although it is not so stout in the petals as some others; and *Devoniensis*, a well-known variety, and one of the most useful in the bud state and even when nearly full blown: I find the climbing variety of this Rose to be the best for forcing, as it makes strong wood similar to that of *Maréchal Niel*, and if treated properly it will produce plenty of

flowers. Safrano and Madame Falcot are also two excellent varieties for very early forcing; their colour is a dark apricot, and their flowers are well suited for button-hole bouquets as well as for other decorative purposes. They make large bushes in pots and flower freely. Next to these I would place Isabella Sprunt, a free-flowering kind, and pretty in the bud state. Of rose-coloured Teas, the two best and freest flowering varieties are Goubalet and Souvenir d'un Ami, both of which may be had in flower throughout the winter; dozens of fine blooms may be cut from them, and they are very useful for specimen glasses, blending as they do with other cut flowers. Last, but not least, let me name Maréchal Niel, which has proved with me quite a gem this winter. I have cut over sixty well-developed flowers off one pot plant of it. It will flower, too, anywhere, even on the back walls of early-forced Vineries, and may be removed to a cooler house when the leaves of the Vine produce too much shade for it. This variety will withstand more heat than many other Roses, and its blooms being very durable, last longer than those of other kinds, and are not so liable to drop. Where red and white Camellias are plentiful, white Roses are not so much required; but Maréchal Niel, being yellow, is very useful. I started a plant of Maréchal Niel last March; when it was out down to the pot, it made fresh shoots, on which there are some thirty fine buds, some of which will open and be fit to cut in a few days. The Teas are free-flowering Roses, but those just mentioned should not be allowed to bloom after May. By keeping the flowers off after that time a good break is ensured the following season, and the wood gets much strengthened. I have managed to force a few Hybrid Perpetuals, but they do not bloom so plentifully as the Tea varieties. The sorts which have done best are Dupuy Jamin, Duke of Edinburgh, Fisher Holms, and Jules Margottin. Cheshunt Hybrid is a beautiful Tea Rose, which forces well, but not among the earliest. Roses to follow the above varieties may consist of Niphetos, Belle Lyonnaise, Madame de St. Joseph, Madame Jules Margottin, President, Catherine Mermet, Marie Van Houtte, Madame Margottin, Souvenir de Paul Néron, Souvenir d'Elise, Céline Forestier, and Lamarque.—H. G.

Hardy Fruit.

The weather during the last week or two having been most favourable for planting operations, such ought now to be near completion, if not wholly finished. Planting in autumn and in winter, rather than in spring, is desirable for this important reason, that the roots must, of necessity, be more or less injured by transplantation; and the longer time such roots have to recover themselves, the greater will be the chances of a successful culture. In winter, when the trees are leafless, and the air humid, roots are not of such importance as in spring and summer, when they are in full leaf, and perspiring through every pore, and the greatest demand is then being made on them. Hence the success invariably attendant on early planting. Sometimes late planting is unavoidable; and, when such is the case, extra pains should be taken to mutilate the roots as little as possible; and, as soon as completed, to mulch the ground immediately over the roots to stop evaporation; and, should the atmosphere be dry when the trees begin to break into leaf, they should be syringed. If we could always ensure having a moist genial spring, and plenty of rain in summer, early planting would not then be of such great importance. Apricots ought ere this to be pruned, and nailed, or tied into position. The bloom-buds are far advanced, and a continuance of the present mild weather will induce some of them to open. Wall-coverings should, therefore, be in readiness to be applied on the least indication of a sharp night. Peaches and Nectarines may also now be pruned. These bear their fruits entirely on the new growth of the preceding summer; and if such growths were not laid in too thickly, but stopped, or pinched off in summer, very little pruning will now be necessary other than thinning out old fruit-shoots, and shortening back the immature shoots to where the wood is firm and well ripened, always taking care to cut to a wood-bud, these being easily distinguished from fruit-buds, which are round and plump, whilst wood-buds are small and conical. If the trees were infested with fly, spider, thrips, or scale last year, dress them with a solution of soft soap, sulphur, and tobacco water, which should be mixed to the consistency of paint by the addition of clay or cow-manure, and applied with a small brush to every part of the trees. If the trees were badly affected, the walls also should be covered over with a similar mixture before tying or nailing the trees. When these operations are finished, clear away all the loose inert top-soil from the border, and replace with good maiden loam, with which has been incorporated wood-ashes and a sprinkling of crushed bones or bone-dust. The pruning of Apples and Pears should be no longer deferred; inferior kinds should be headed down, and be re-grafted with better kinds in March, for which purpose collect scions and heel them in till wanted at the foot of a north wall

or other sunless spot to prevent the too early bursting of the buds. Strawberry plants that were not mulched previous to the late frosts will, through its action, have become loosened in the ground, and to prevent further injury they should be trodden down again into the soil and at once thickly mulched.—W. WILDSMITH, *Heckfield*.

Floral Decorations.

The following list of cut flowers procurable during the present month, although embracing most of those which were mentioned in our list for January, nevertheless contains some important additions. Cinerarias are now coming in, but will not be plentiful before the end of the month; they last well in water, and many of the varieties present very effective candlelight combinations. *Dilytra spectabilis*, with its lovely pink heart-shaped blossoms quivering on slender stalks, is one of the most beautiful objects that can be found for tall vases, looking well with its own pale green foliage or mixed with *Cyperus* or Ferns. For large vases and bold effects there is no white flower more valuable than the African Arum (*Calla æthiopica*), which, however, should always, if possible, be arranged either with its own leaves or with foliage equally large. The forced flowers of the delicate transparent white Bladder-nut (*Staphylea trifoliata*) may now be had, and are a welcome addition to the bouquet maker, forming, as they do, one of the prettiest coat flowers that can be worn. The beautiful yellow Azalea and invaluable Japanese *Spiræa* (*Astilbe japonica*), are now coming in, and will be at our service for some months; but double-blossomed pink and scarlet *Pelargoniums* are not to be depended upon, neither is it safe to calculate upon *Stephanotis*, *Gardenias*, or *Begonias*. Nevertheless, the list is sufficiently rich in varieties, both of form and of colour, to satisfy any reasonable decorator; besides which, for those who can afford it, there is a numerous selection of Orchids from which to choose.

Blue.—Hyacinth, Siberian Squill.

Purple.—Heliotrope, Hyacinth, Violets.

Mauve.—Heath, Tulip.

Pink.—Azalea, Bonvardia, Camellia, Carnation, Chinese Primrose, Cyclamen, *Dilytra*, Epiphyllum, Fuchsia, Heath, Hyacinth, Rose, single zonal *Pelargoniums*, Tulip.

Crimson.—Bonvardia, Camellia, Cyclamen, Epiphyllum, Fuchsia, Hyacinth, Rose.

Scarlet.—Bonvardia, Carnation, Euphorbia, single zonal *Pelargoniums*, Tulips. Also berries of *Arbutus*, *Aucuba*, *Cotoneaster*, and *Solanum*, together with seed-pods of Iris.

Orange.—Carnation, *Narcissus*, Tulip.

Yellow.—Azalea, Genista, *Narcissus*, Rose, Tulip.

White.—*Andromeda*, *Arbutus*, Arum, Azalea, Bouvardia, Cineraria, Camellia, Carnation, Chinese Primrose, Cyclamen, Eucharis, Heath, Hyacinth, Lilac, Lily of the Valley, *Narcissus*, Paper *Narcissus*, Roman Hyacinths, Rose, *Spiræa*, *Staphylea*, Tulip.

—W. T. T.

VAN HOUTTE'S "FLORE DE SERRES."

THE fourth triple part of the twenty-first volume of this work has reached us, bringing this volume to a conclusion; and though it contains the unusually large number of thirty-one coloured plates (ten double and eleven single page illustrations), it is certainly the least interesting instalment of the work that has come under my notice, as, with the trifling exceptions of a hardy hybrid Azalea of no great beauty named *Diamant*, and a yellow Tea Rose of no great substance named *Amazon*, raised by Monsieur Ducher, none of the plants or trees figured in the numbers just alluded to are either new or unknown to English readers. I notice also a falling off in the finish and beauty of the execution and colouring of several of the plates, and many of them are, as has been so often the case lately, borrowed from other works both English and Continental. The plants figured on double plates are as follow:—*Æsculus rubicunda*, *Artocarpus Cannonii*, Azalea *Diamant*, *Cerasus Caproniana flore roseo-pleno*, *Chlorophyllum elatum* (one of the many synonyms of the plant figured under the name of *Antericum variegatum* in the "Floral Magazine," t. 1179), *Cytisus Laburnum aureus*, *Godwinia Gigas*, *Heliampora nutans*, *Ravenalia madagascariensis*, as seen in its native habitat, *Renanthera* or *Vanda Lowii*; and on single plates, *Bertolonia Mirandei*, *Bolbophyllum Dayanum*, *Bryonopsis laciniosa*, *Erythrocarpa*, a small hedge of twenty-nine *Lilium Brownii*, *Linaria tristis*, *Masdevallia Harryana*, *Picea alba*, a mass of *Richardia alba maculata*, *Tea Rose Amazon*, *Rubus spectabilis*, *fructu rubro et luteo*, and *Tulipa Greigi*. W. E. G.

The Japan Privet (T. P.)—This is perfectly an evergreen, and one which forms very large specimens in warm positions in the southern counties, thriving fairly well in London. In Rome it is used as a street tree, and forms a handsome one, being trained like a large standard Orange.

PROPAGATING DAHLIAS.

DAHLIAS are easily propagated either by means of seeds, cuttings, dividing the crowns, or by grafting, and each mode has its own especial merits. Seeds should be saved from the best varieties, and it is a singular fact that, as in the case of the Rose, the earliest flowers do not produce fertile seeds. Towards the end of August the plants intended to bear seeds should be thinned out, leaving only two or three good flowers on each from which to obtain seeds, and if not perfectly ripe on the approach of frost, the branches with the flowers on them should be cut off and placed in glasses of water in a warm sunny greenhouse to ripen. The seeds may be sown in heat in February so as to be ready for planting-out in June. Old tubers placed in a genial bottom-heat in spring yield plenty of cuttings, which, when taken off with a heel in February or March when 4 or 5 in. in length, root freely. They should be potted in any light compost, and should be plunged in a bottom-heat of 75° or 80°. When well rooted they should be hardened off preparatory to planting out after all danger from frost is over. Grafting is useful where it is desirable to give seedlings or delicate

Grafting Dahlias.

varieties a good start by working them on a rooted piece of the tuber of some common variety. A slice of the fleshy bark is taken off each side of the cutting-like scion or graft, and a corresponding slit or cleft having been made in the stock, the two are fitted together as shown in our illustration; and, after being firmly bound, the two are potted in warm soil, and plunged in a gentle bottom-heat, until a union is effected. The lower point or heel of the scion is left exposed, and not infrequently emits roots itself, after a union with the stock has been effected. Grafting is especially applicable in the case of such large-growing species as *D. imperialis*, which naturally attains a height of from 10 to 15 ft.; but, grafted on one of the florists' dwarf varieties, its growth becomes much more dwarf and bushy, and also more floriferous. This experiment was tested several years ago by the late Mr. Salter, of Hammersmith, and found to answer perfectly; and by propagating this plant in this manner, it becomes better adapted for pot culture as a decorative plant, forming a useful ornament to a warm conservatory in autumn, when covered with its large white-rayed, well-shaped flowers. B.

Fan-shaped Bouquets.—Captain Raikes' fan-shaped bouquets (see p. 75) can by no means lay claim to being either original or new; on the contrary, they are amongst the oldest in use in the northern and midland districts. I have even seen them exhibited at flower shows, between thirty and forty years ago. They are as old as the one-sided plants to be seen in cottagers' windows, and just about as handsome, for no matter how tastefully they may be put together their one-sidedness gives them a formal unnatural appearance.—T. BAINES. [Captain Raikes' bouquet, which Mr. Baines did not see, was distinct from the old and well-known type to which he alludes. We think, however, the fan bouquet might yet be greatly improved in point of lightness.]

THE ROYAL HORTICULTURAL SOCIETY.*

By WILLIAM A. LINDSAY.

THERE are few learned societies which can boast of so interesting and remarkable a history as can the Horticultural Society of London. At the present time, when its affairs appear to have become so complicated as almost to defy the comprehension of the public, a short summary of its history may not seem altogether unprofitable. Strange as it may seem to us, who now live surrounded by such a marvellous number of brilliant flowers, it is nevertheless true that, previous to 1737, but few even of the hardier plants had been introduced into this country. The Rhododendron and Azalea, now such conspicuous ornaments of every lawn and conservatory, were practically unknown in English gardens, and it was not till the middle of the century that the Royal Botanic Gardens were established at Kew. There had, however, been founded in 1684 a nursery to the west of the metropolis, by the spirited gardeners named London and Wise. John Evelyn notices it, and it was without doubt a very important undertaking, probably, however, directed rather to the culture of trees and shrubs than to that of flowers. Of the antecedent period it must suffice to relate, with Mr. Murray, that in the account of English gardens which Didymus Mountain published at the end of the sixteenth century, "the handsome flowers he could name were Jasmines, Damask Roses, Rose Campines, Pinks, Heartsease, Gilliflowers, and Carnations." The Horticultural Society possesses a small water-colour drawing, representing Mr. Rose, gardener at Hampton Court, in the act of presenting the first Pine-apple grown in England to Charles II. The use of heated houses began to be more generally practised in the first half of last century, and it is a curious commentary upon the state of civilisation in England, that a practice which certainly obtained among the Romans, should so many centuries later have been an "exotic" in a climate so much more in need of it than that of Italy. It is thus no exaggeration to state that, during the eighteenth century, little horticultural knowledge existed in this country. The first person to whom the idea occurred of founding a Society for the furtherance of such knowledge was Mr. Thomas Andrew Knight, who had become known as the author of several original communications to the Royal Society. Living in Herefordshire, in a perry and cider-making country, the loss which resulted from the ignorance of those engaged in this industry attracted his attention. Mr. Knight proceeded to consult Sir Joseph Banks as to the desirability of establishing a Society for the diffusion of horticultural knowledge, and the suggestion was most warmly approved by him. Mr. John Wedgewood was also conferred with, and in the result a meeting took place at Messrs. Hatchard's book-shop in Piccadilly, on March 7, 1804, composed—in addition to the above-mentioned gentlemen—of Mr. Richard Saltusbury, Mr. Charles Greville, Mr. Acton, Mr. Forsyth, and Mr. Dickson. The meeting resolved that a new Society should be formed, "to collect every information respecting the culture and treatment of all plants and trees, as well culinary as ornamental, to foster and encourage every branch of horticulture and all the arts connected with it. And that it shall be considered within the intention of the Society to give premiums for improvements in horticulture, whenever it should be judged expedient to do so." The moment was, however, unfavourable to such peaceful labours, and England was in a state of enmity with the French people, just about to create Napoleon Bonaparte Emperor, and to overrun the Continent with renewed invasions; and amid wars and rumours of wars the new-born Society—destined to bear no inconsiderable part in the weightier revolution of thought which has followed the study of natural science—was not likely to attract much popular attention. Its labours were, nevertheless, intended to be at once practical. From the instructive paper read by Mr. Knight on April 2, 1805—the first recorded production of the Society—we quote the conclusion:—"In the execution of their plan, the Society feels that they have many difficulties to encounter, and some prejudices to contend with; but they have long been convinced, as individuals, and their aggregate observations have tended only to increase that conviction, that there scarcely exists a single species of esculent plant or fruit (relative to the use of man) has yet attained its utmost state of perfection, nor any branch of practical horticulture which is not still susceptible of essential improvement; and under these impressions they hope to receive the support and assistance of those who are interested in, and capable of promoting, the success of their endeavours." It would be impossible to refer even to the index of valuable papers which follow. Of those more peculiarly interesting we may, however, specify that read by Sir Joseph Banks on the "Introduction of the Potato" (May 7, 1805). From it we learn that this vegetable (to our knowledge of which the Horticultural Society has been the principal contributor) was introduced by Sir W. Raleigh in 1586 and that Sir Robert Southwell stated to the Royal Society in 1693

* "St. James' Magazine."

that Raleigh had given it to his grandfather, who conveyed it to Ireland; that Celsus, of Vienna, received it in 1598 from the governor of Mons, in Hainault, who received it himself from an attendant of the Pope's legate under the name of Paratoulli.

On April 17, 1809, was granted a charter incorporating the Horticultural Society. The Earl of Dartmouth was created president, Mr. Charles Greville treasurer, and Mr. Richard Salusbury secretary. The members of the first Council were the Earl of Powis, the Bishop of Winchester, Lord Selsey, Sir Joseph Banks, Messrs. Acton, Elliot, Knight, Miller, Trevelyan, Dickson, Hoy, and Smith. Three members were to retire at each annual meeting, and to be replaced by others. Between 1804 and 1809 a gradual increase of members had taken place. The grant of premiums had had the most beneficial effects on practical horticulturists, and patronage only was required to ensure success. The publication of the "Transactions" in the form of volumes began in 1812, and it may here be stated that the total number of these volumes cost the Society no less a sum than £30,000. They were without doubt a powerful means of attracting support, and are still of considerable literary value. At this period of its existence, the Society paid the modest sum of twenty-five guineas a year to the Linnean Society for a share of their accommodation in Gerrard Street, thus commencing a friendship between the two bodies which has always continued to subsist.

In 1811 Mr. Knight succeeded, on the death of the Earl of Dartmouth, to the presidency. He retained the post until his own decease, twenty-seven years later. A large portion of the Society's more valuable work was thus performed under his guidance, and is now bound up with his memory. But in 1811 and following years, the causes which impeded the early progress of the Society increased in force. Europe was the scene of universal war, and England continued to be the principal European power in arms against France. At such a time, and amid the popular excitement in which all classes of society were involved, little progress could be looked for in such an enterprise. Elections were few; but a careful Council kept the expenditure within the income, and each year added a small sum to the Society's balance. This amounted to £258 in 1815, when the return of peace restored the thoughts of the people to legitimate channels. The labours of the Horticultural Society had entitled it to be considered as one of the most useful institutions, and all things thus tended to the approach of prosperity. In May, 1816, there were invested in the Three per Cents. £1000. Elections took place with greater frequency, and in 1818 the income was £1791, and the expenditure £1719, while the funded property was £1400, and the value of the stock £9000 in excess of all debts. An experimental garden was now established at Kensington, and a nursery at Ealing. A house in Regent Street was bought, in 1820, for £4200; and although

the subscriptions were raised from two to three guineas new Fellows poured in at the rate of 200 or 300 a year. In issuing the second volume of "Transactions" (1818), the authors of the preface express themselves as follows:—"The Society can hardly be said to have emerged from its infancy; yet it already displays a degree of vigour which is not only calculated to render its present labours beneficial, but holds out the most flattering hopes of what it may accomplish hereafter." Its internal operations "lie open to the judgment of the public in the increased number of the written communications, of which the 'Transactions' furnish the result, in the frequent and various exhibitions of produce at the meetings, and the supply of seeds, grafts, and plants which are distributed. A connection has, for these purposes, been established with almost every part of the globe, by means of the corresponding members, which have lately been instituted." The Society "takes under its care all the variety of produce which the garden can yield, as food and sustenance to man." This preface concludes with the following valuable distinction—"Agriculture performs its operations in the gross, and upon an extensive scale; it may occasionally furnish the gardener with new ideas, and suggest contrivances and manipulations that may facilitate and further his labours. Horticulture, on the other hand, acts in detail; it works with more precision and nicety, and its refinements may sometimes prove of no small benefit to the sister art. Both are employed in the cultivation of the soil, and in eliciting the gifts of the earth; if the one be honoured, the other must also lay some claim to regard."

The practice of collecting seeds from abroad had begun in 1815, and now Mr. John Reeves commenced sending over plants from China. The East India Company assisted in the work, and by these means the Society introduced into England many varieties of Camellias, Indian Azaleas, Chinese Peonies, and Chrysanthemums. Mr. Reeves sent the first Wistaria (Glycine) sinensis, a plant which, we believe, still flourishes in Chiswick Garden. All seeds and plants addressed to the Society were freed from Customs duty by order of the Lords of the Treasury. The importance of sending out collectors to foreign countries now began to be felt and acted upon. "At first," says Mr.

Murray, "their attempts in this direction were feeble and hesitating, but with success their scope expanded until they produced results which have affected the appearance of all England. Nowhere can a day's ride now be taken, where the landscape is not beautified by some of the introductions of the Horticultural Society." The first successor to Mr. Reeves was Mr. George Don, who travelled on the western coast of Africa, Mr. John Forbes, and Mr. Potts. Mr. Don alone survived his exertions. Forbes was succeeded by the German botanist Hilsenberg, who had been residing at the Mauritius. Mr. John Dampier Parks was sent to China, and Mr. David Douglas to North America. This last collector was one of the most famous. He enriched this country with a large number of Conifers and fruit trees. Finally, Mr. James M' Rae, a gardener of great practical experience, travelled to the Sandwich Islands in the frigate *Blonde*. With him the series closed, there having at a later period been three more collectors, of whom we shall speak hereafter. In 1822 the establishments at Kensington and Ealing were given up, and a garden was acquired at Chiswick on a lease from the Duke of Devonshire; and in the following year 1200 kinds of Roses flourished on this spot. In 1822 the Society lost its first great protector—Sir J. Banks.

Subscriptions were now invited for the works which it was determined to undertake in the new garden. Not only were the annual subscriptions raised in amount, but a further sum of £2775 was voluntarily contributed by the Fellows. The Society commenced in 1825 daily meteorological observations, which were for a long period recorded by Mr. Robert Thompson, and have never been abandoned—forming the largest and most trustworthy chronicle of the London climate in existence. But the Society now began to experience reverses. An officer absconded with a large sum of money, and a feeling of distrust for the management resulted. A further cause of dissatisfaction was the abandonment of an annual dinner and the substitution of public breakfasts, thus inviting fashionable support rather than attempting to maintain and stimulate that *esprit de corps* which is so essential to all public bodies. The breakfasts were abandoned in 1831, and were succeeded, on the suggestion of Dr. Lindley—the assistant secretary and well-known botanist—by garden exhibitions. These became exceedingly popular, and retained public favour for a long period of time. Nevertheless, the financial position was most critical. A committee of inquiry was appointed in 1832, which reported that the debts amounted to £20,243, and that the value of the property was but £16,500. The cost of the garden works had exceeded the sum subscribed for them by £29,000. The management was condemned, and, in consequence, Mr. Sabine resigned the secretaryship, to be succeeded by Mr. Bentham. A determined attempt was made to retrieve the Society's position, but it was considered of paramount importance to maintain the scientific work. Between 1830 and 1855, in addition to the money allotted to the payment of debt, £11,000 was spent on the garden and £7000 on foreign importations. Mr. Knight died in 1836, having been, as Mr. Murray records, the chief mover in all the Society's proceedings from its origin. No successor could hope to fill his place in so far as scientific ability was a necessity; but in devotion to the Society's interests he has fortunately found rivals. The Duke of Devonshire was elected President—a nobleman who had availed himself of the many opportunities he possessed for benefiting the Society. Under his *regime* Mr. Hartweg was sent to Guatemala; and in 1842 Mr. Fortune—who had commenced his great services to horticulture as superintendent of the hot-house department at Chiswick—started for China, and was the introducer of many valuable plants indigenous to that country. His principal fame was, however, acquired by the study of the cultivation and manufacture of Tea. His mastery of this subject resulted in his appointment by the East India Company to establish that industry in their possessions. Notwithstanding the enthusiasm which all these labours and successes must have stimulated, the Society was much hampered, as all such bodies are, by the non-payment of subscriptions. No less a sum than £12,879 had to be abandoned as irrecoverable between 1824 and 1855. Had it not been for this unhandsome conduct, it may be doubted whether any serious debt would ever have been incurred. At no time since 1828 had the liabilities exceeded £14,331, and, at the period of which we are speaking, the total debt had been reduced to £9986. The exhibitions now began to fail. Their popularity had raised up competitors nearer to London than Chiswick, and the public accordingly recoiled from the distance of the latter spot. In 1855 Her Majesty's Commissioners for the Exhibition of 1851 lent Gore House and its grounds to the Society, but it was not found that the tide of prosperity ceased to ebb. The exhibitions were a source of loss instead of profit, a result which continued to attend them, when a few Fellows subscribed to restore them at Chiswick. An address was accordingly issued by the Council on the 29th January, 1859, stating that the exhibitions would be given up, and the garden maintained only for experiments; also, that it had been determined to give up the house in Regent Street as too expensive, and conse-

quently, to sell by auction the collection of books which had been amassed during the previous forty years. An office was then acquired in St. Martin's Place, Trafalgar Square, at a rental of £80 a year. The effect of these changes was not merely to reduce the annual expenditure, but to bring down the liabilities to £4694, as against a floating property valued in 1857 at £14,674. We have been thus particular in recording the financial position of the Society in 1859, because it has constantly been misrepresented, and because it is only with a full knowledge of the details given that the extraordinary changes which followed can be truly criticised. In 1858-59 the annual subscriptions amounted to £2322, and the income from all sources in that year was £3810, to meet an expenditure of £3416, with a further liability on the year of £939. The outgoings have been, as we have shown, reduced by the changes we have chronicled, so that the position could certainly not be termed desperate. The Society was less insolvent than it had been since 1828, and there is no reason to suppose that the policy determined upon would have failed to maintain its condition, and to re-establish its finances, in whatever degree it may have lost prestige.

The Duke of Devonshire died in 1858, and H. R. H. the Prince Consort graciously allowed the Society to elect him as their new President. The introduction of this master-mind into the Society's Council resulted in a scheme of extraordinary magnitude and splendour. The Prince, being also at the head of the Commissioners for the Exhibition of 1851—who were endeavouring to settle on some plan for the laying out and embellishing of their newly-purchased estate in South Kensington—conceived the idea of bringing the two bodies together, and of making a Horticultural Garden as an integral part of the Commissioners' design. A correspondence took place on this subject between the respective officials, and on July 7th, 1859, a special general meeting of the Society took place, at which a scheme was submitted and generally approved by the Fellows. It was proposed that £50,000 should be spent on each side; the Commissioners to erect architectural buildings round the garden, and the Society to lay out the grounds; that a lease should be granted for thirty-one years with a right of renewal or of receiving a stated compensation for disturbance; that the Society should pay by way of rent such sum as should remain after the payment of the interest due on the amount it should borrow, and of the sums necessary for the maintenance of the garden, until the whole of the interest due on the Commissioners' outlay should have been met, and then half of any further surplus; finally, that a right of re-entry should accrue to the Commissioners, if the stipulated minimum of rent should fail to be paid for five successive years. An arrangement was ultimately made on the basis of this scheme. But in regard to the last item, it is material to notice that on the 20th July the following resolution was passed by the Fellows: "That the Council be instructed not to accept the clause about renting in case of failing to pay interest for five years, and that in the event of the Commissioners cancelling the lease, an equitable adjustment of mutual interests be made." No trace exists of any subsequent attention on the part of the Council to this somewhat decisive and peremptory minute. In order to enable the Society to enter upon this undertaking, a new charter was granted by the Queen. In consideration of the distinction enjoyed by the Society in the person of its President, the title was altered to that of the Royal Horticultural Society. The Prince Consort was created President. No material difference exists between the new and old charters except that the previous inability to remove the Council seems to have been taken away. The sum of £50,000 was raised on the security of debenture bonds, and, surprising as it now seems, the money was subscribed with great rapidity. Her Majesty made a donation of £1000, and purchased life-memberships for all her children except the Princess Royal of Prussia, who herself became a life-member; a course which was also adopted by the Royal Highnesses the Duchess of Kent, the Duchess of Cambridge, and the Princess Mary of Cambridge. The example thus set by the royal family was followed by about five hundred other persons, including many of the highest rank.

The annual report presented in 1860 was couched in very different terms from that of the previous year. We read that "great retrenchment in a public body was too dangerous a course to be permanently adopted. It could only be effected by inaction." The debt had been reduced to £4296, and "liabilities so small as these have ceased to have any significance;" for the Council "entertain the confident belief that the Society is now entering upon a career of utility and prosperity such as it has never before experienced." On the 19th of March, 1861, the Council obtained permission to increase the outlay to £70,000. The formal opening of the new garden took place on June 5th, 1871. Her Majesty the Queen paid a private visit early in the morning to the grounds, and was accompanied by His Majesty the King of the Belgians and H.R.H. the Prince Consort. The Queen

of the French and the Duc de Nemours also visited the garden. The extraordinary enthusiasm with which this great work had been undertaken was fully manifested in the ceremony which followed later in the day. A procession formed of the workmen engaged, and of the officials of the Society, together with a large number of the Commissioners, was followed by the Prince and ten other members of the royal family. The Prince Consort made, in answer to an address read by Dr. Lindley, one of those admirable speeches which so often indicated the deep and original reasoning power of his mind. After referring to the labours in which he had shared, His Royal Highness said:—"That which last year was still a vague conception, is to-day a reality; and I trust will be accepted as a valuable attempt, at least, to reunite the science and art of gardening to the sister arts of architecture, sculpture, and painting. This union existed in the best periods of art when the same feeling pervaded and the same principles regulated them all; and if the misuse and misapplication of these principles in later times have forced again upon us the simple study and imitation of Nature, individual arts have suffered by their disjunction, and the time seems now arrived when they may once more combine, without the danger of being cramped by pedantic and arbitrary rules of taste." Special prayers were then said by the Bishop of London; after which one of the finest exhibitions of flowers and fruit ever witnessed was opened to the public.

The pomp with which it had thus been surrounded did not prevent the Society from reverting to one at least of its more appropriate labours. Mr. Weir was sent out as a collector to Brazil. His exertions were of the greatest advantage to the Society; but at last, after enriching this country with several new plants, he succumbed to fever and paralysis, and was sent home. No collector has since been employed by the Society. It was in the midst of the difficulties which had to be surmounted for the complete success of the South Kensington establishment that the Prince Consort died. Of the loss which the country thus sustained it is needless here to speak. The effect on the Royal Horticultural Society was irreparable. Nothing but the prolongation of the prince's life could have made success in its new operations possible. Saddled now with a boded debt of £50,000, having to maintain a garden which could, under no circumstances, cost less than £3000 or £4000 a year, in addition to the experimental ground at Chiswick, on what had it to rely for an adequate income? On voluntary subscriptions only. A yet more serious danger than that of uncertainty of revenue was unforeseen, and could only be apprehended as it became manifest. The Commissioners for the Exhibition of 1851 and the Society gradually ceased to be animated by a common aim. Further, the Society had an inherent difficulty to contend with. As a general rule, learned societies are able to assume that those who seek admission into them have for their object the promotion of the special science or art in the interests of which they are incorporated. Previous to 1860 the Horticultural Society had been no exception to this rule. But now other motives might, and often did, prevail—motives connected with the use of the new garden as a place of recreation or of social entertainment. A large number of Fellows was thus admitted who knew nothing and cared nothing for the magnificent work which the Society had done, and who had no interest in its being resumed. From 1860 to the present time matters have proceeded from bad to worse. 1862 and 1871 were the only years in which the income availed for the discharge of all the annual engagements, and in each year success was owing to the existence of an International Exhibition. In 1873, a Council composed largely of men known to the world of science was displaced by the Fellows, under great provocation, and their places were supplied by gentlemen instructed particularly to maintain the rights of the resident Fellows. Each successive Council has done its utmost to avoid failure, and these efforts appear still to be prolonged, but as yet with little result. Men of science begin to look on the Society with suspicion, and the residents at South Kensington seem to care little to support its garden.

What then should be the cure for such prostration? We have shown, historically, that the Society has been remarkable for three special kinds of external work in addition to the internal labour of its committees and officials. These are—1. The publication of papers on details of horticultural science. 2. The mission of foreign collectors. 3. The holding of exhibitions. In the latter the Society has now many rivals. The Royal Botanic Society, the Crystal Palace Company, and many other bodies scattered over the country, hold these shows with success. It is a mere question of money. Whoever gives the largest amounts in prizes will secure the best exhibition. Consistently with retrenchment, the Society can maintain no pre-eminence in such work. The mission of foreign collectors is now undertaken by several of the principal nurserymen; and we believe that some of these expend a large time every

year in this branch of their trade. A practice which was of great value at a time when no individual in the country had energy to adopt it, ceases to be important when a large portion of the globe has been explored, and the remainder is being diligently investigated by private persons. The publication of papers remains, and in this special department the Horticultural Society has as yet no competitors. But to publish on a scale equal to the early "Transactions," the Society must expend large sums. Crippled as it is with a garden (and a debt) such as that in South Kensington, no such publication is possible. It appears, then, to follow, that either all scientific work of a kind to attract the public and maintain the world-wide reputation of the past must be abandoned by the Society, or the garden at South Kensington must be given up. The garden itself is, horticulturally, a failure, and its beauty principally architectural. Flowers can only be brought there to expend the luxuriance they have elsewhere acquired. As a place for exhibition, it is needlessly large. As a meeting-place for the local Fellows it may have some value of a social kind; but to maintain a garden with this object is hardly within the scope of the Society's work. Melancholy, then, as it is to confess that the brilliant scheme of 1860 has failed, it is impossible to resist this conclusion, and it would be foolish any longer to shunt our eyes to it. A Society which has contributed so much to the beauty of English life has some claims on the national gratitude, so long as it fulfils its vocation. It is our earnest hope, therefore, that its Council will ere long apply their energies to the liberation of the Society from its engagements, and to the resumption of scientific work at Chiswick. Some convenient office in London could again be opened where meetings might be held, and a new library be collected. In this way only can the extinction or degradation of the Society be avoided. But if no such restoration take place, and if it should appear that the mission of the Royal Horticultural Society has been fulfilled, it will have contributed in no small degree to science and art in England. Its publications form a library of important papers; and its labourers have created the modern garden. Of the latter we have spoken. As to the former, it must suffice again to remind the student that no education in natural science can be considered even approximately perfect which has not included their personal. There is no step in the ascent of knowledge which they do not illustrate; and as the reader rises from the consideration of the special flower to the comprehension of the class, and from the examination of such laws as govern heat and chemical action in relation to the vegetable kingdom, to that point at which all natural sciences appear to converge, he cannot but feel that had it not been for the Royal Horticultural Society his education must have begun at a far lower stage of knowledge.

Potato Crops.—Last spring Messrs. B. K. Bliss & Sons again offered premiums for the largest yields from 1 lb. each of Snowflake and Eureka, two of their new varieties of Potatoes. The awards have been made, and a full report of the committee will soon be published. The returns are simply astonishing, but they are thoroughly substantiated by evidence and affidavits. Such large yields were of course obtained by every legitimate aid—the eyes of the Potatoes, greatly sub-divided, and soil already very rich, pushed to its utmost with fertilisers. The report gives many interesting particulars; here we ("American Agriculturist") can only give the yields and the awards. Largest yield of Snowflake from 1 lb. of seed—first prize to Mr. P. C. Wood, Esther, Ill., 1417 lbs.; second prize to Mr. J. L. Perkins, Little Sioux, Iowa, 1304 lbs.; third prize to Mr. Seiler, Verona, Essex County, N. J., 1125 lbs. The largest yield of Eureka from 1 lb. of seed—first prize to Mr. Perkins, Little Sioux, Iowa, 1666½ lbs.; second prize to Mr. Wood, Esther, Ill., 1403 lbs.; third prize to Mr. Alfred Rose, Penn Yan, N. Y., 1149 lbs.

Prizes Offered by the Westminster Aquarium Company.—For the exhibition to be held on April 12th and 13th there are thirty-one classes, amongst which we note a first prize of £12 for twenty standard Azaleas, and a similar sum for fifty plants of *Cyclamen persicum*; a first prize of £7 is offered for twelve forced *Rhododendrons*, and £1 for six *Orchids* (amateurs and nurserymen); and for three plants of *Coccolyne cristata*. On May 10th and 11th the leading first prizes are—£25 for twelve Roses in pots (open); £10 for six *Roses* in pots (amateurs); £18 for twenty *Roses* in 8-in. pots (open); £12 for twelve new and rare plants; £12 for twelve distinct *Dracenas* (nurserymen); £10 for eight gold and silver tricolor *Pelargoniums*. The show on May 30th and 31st ought to be a good one inasmuch as there are seventy-two classes, and the highest prizes offered are £50, £30, and £20. Amongst the other chief prizes are £25 for twelve stove or greenhouse plants, and £15 for eight of a similar kind; £20 for twelve *Orchids* (nurserymen); £12 for eight *Orchids*, twelve new plants, eight greenhouse *Azaleas*, eight show *Pelargoniums*, nine

fine-foliaged plants, four tree Ferns, &c. On July 5th and 6th *Roses* will be the chief feature, the highest prizes being £10 for seventy-two single trusses, forty-eight varieties, three trusses of each, and forty-eight single trusses (amateurs), and twenty-four *Roses* in 8-in. pots. Four prizes of £25, £20, £15 and £10 respectively will be awarded at this show for dinner-table decorations. For the exhibition of fruit on October 4th and 5th there are sixty-eight classes, the prizes in all cases being very liberal. Six classes are provided for exhibitors from the Channel Islands and English fruiterers who cannot compete in any others.

Schreiber's True Friend Lamp Stove.—This will be found valuable in winter for heating small plant structures, of which there are hundreds scattered over the suburbs of London. With such houses all goes well during summer, but when the dark, dull days of autumn set in, and damp and frost make their appearance, the want of some heating power is seriously felt. The question naturally arises, what contrivance will best enable us to overcome these evils? I unhesitatingly reply, this lamp stove, which is both cheap and economical. My greenhouse is a tolerably large one, and, unfortunately, owing to having to be raised so that the floor might be on the same level as that of the sitting-room; it is open beneath, and, therefore, frost attacks it below as well as above. Under these circumstances, I gave this stove a trial during the severe weather, just before Christmas, and it proved satisfactory. It has a powerful German round burner, by which means the air is heated in passing through the stove, without emitting any unpleasant odour, or becoming in any way injurious to the plants. I have burned this stove forty-eight hours at a stretch, and the plants have not suffered in the least, but, on the contrary, looked as healthy as could be desired. I use ordinary paraffin oil of good quality, and when the lamp is burning I frequently take off the lid at the top, and place on the opening a common garden pan filled with water. This becomes heated in a short time, and gives forth steam, which moistens the air, and no doubt benefits the plants.—R. D.

L A W.

ALLEN v. MARTIN.—This was an application in the suit relating to the Euston Square garden, which has been left in such a disgraceful state for months past by a contractor who had undertaken to put it in proper order. In July last an order was made that the defendant Martin should stand committed to Holloway prison for disobeying the injunction of the Court by continuing to excavate gravel and to shoot dust-bin refuse in the Square garden, which he was under contract to put in order. The order for committal was not, however, put in force till October, since which date the defendant had been in custody. He now applied for his discharge, having made an affidavit submitting himself to the clemency of the Court, and further undertaking to cancel the contract and not to interfere further with the garden. Mr. Romer, for the applicant, submitted that the defendant, having cleared his contempt of Court, should not be detained in further custody till the costs of the commitment were paid. Mr. Edward J. Foster, for the plaintiffs, contended that the payment of these costs should be made a condition precedent to the defendant's discharge, his inability to pay these costs not being established. The Vice-Chancellor said that since the Debtors' Act, 1859, he could not keep the defendant in prison until these costs were paid. There must be an order for discharge, in which might be stated the undertaking of the defendant with respect to cancelling his contract. The order would also direct that the costs of the commitment and of that application should be paid by the defendant, and the plaintiffs would be left at liberty to enforce that order as they thought fit.

NOTES AND QUESTIONS—VARIOUS.

Prince Albert Pine Apple.—I cut up a small fruit of this variety last week, and found it in all respects excellent. Inside it is deep yellow and almost scarlet outside. In form it is conical and handsome, and when better known it cannot fail to be largely grown.—R. GRUBER, *Essex*.

Echinonea grandiflorum.—This beautiful plant, figured in *THE GARDEN* last week, is very impatient of transplantation, and hence there is some difficulty in its culture. Seedling plants are the best, and they should when young be planted where they are to remain. They will in time form very neat bushes. It is a true rock plant, and one of the best we have.—R.

Tuberous-rooted Begonia Grubs.—Everyone of the tubers of these *Begonias* should now be closely examined, as they are unfortunately liable to the attacks of a white grub or larva, similar to that which bores through and destroys the roots and crowns of *Primula cortusoides amana* and double *Primroses* when grown in pots. It eats into the heart of the tuber and causes it to decay, if not discovered and removed in time. The eggs of this troublesome insect must be deposited in the soil the season previous. Fortunately their white colour renders them easily visible to the careful eye.—G.

Cologne Exhibition.—The Commissioners of this Exhibition have awarded to Messrs. Dennis & Co., of Chelmsford, who were the only British exhibitors of horticultural buildings, a diploma, gold medal, and 2000 marks for their Victoria Regia house, and also a diploma and 750 marks for the heating apparatus for the same. Mr. Laing, of Forest Hill, has also received a diploma and medal.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE WILD GARDEN IN SPRING.

ONE of our brightest harbingers of spring, and doubly welcome on that account is the gay little winter Aconite (*Eranthis hyemalis*); it may well be called the winter Aconite, blooming, as it does, in the earliest spring months, and often before the snow is off the ground its little yellow flowers are seen perched on whorls of shining leaves, somewhat resembling the "ruffs" of our forefathers. This useful little subject should be planted abundantly not only in the wild garden, but on slopes in the pleasure-ground, in the bays of shrubberies, and under the branches of deciduous trees. It may even be introduced towards the outer edges of the lawn as its foliage dies down sufficiently early not to interfere with the mowing of the Grass. A few patches, carefully planted here and there, will soon increase, and its cheapness should be an additional inducement to its being grown abundantly. In the wild garden it is quite indispensable. Here, we have it everywhere in large masses peeping through carpets of the small Periwinkle (*Vinca minor*), blue, white, and purple, and the effect is very good. The bloom of the *Vinca* is a trifle later than that of the Aconite, but they flower so nearly at the same time that both are often in bloom together. There are double forms of the *Vinca*, but I do not think them so good as the single ones. *V. rosea* has very small pretensions to its name, being a purple blue. *V. major* is almost too rampant, except for very wild spots, under trees or elsewhere, in which it will be found useful. It is surpassed by its variegated form, which is a very desirable plant. *Vinca herbacea* is more fitted for the garden, as it is not so vigorous as the preceding. It has herbaceous stems, and succeeds better in open spots. The Winter Aconite is, however, not the only spring flower set off by the dark green leaves of the Periwinkles. The Snowdrops, both double and single, are equally numerous, and are too well known to need any tribute of praise. A single Snowdrop flower is exquisite, but the effect is proportionately enhanced when we see them (as here) in thousands and thousands. A rarer species is *Galanthus plicatus*, which must, at present, be confined to the flower garden, at least till it is more plentiful. It is not a plant commonly seen, though it has been introduced several years. The flower resembles that of the common Snowdrop, but it is a trifle smaller, the bulb, on the other hand, being larger. The name *plicatus* has been given to it from the appearance of its leaves, which are folded lengthways near the edge, and on both sides. It comes from the south of Russia, and blooms in February and March, and occasionally in April. I have seen the names also of *G. reflexus* and *G. Imperati*, but do not know anything about them. In the shrubberies here, on each side of a long avenue, we have the common *Crocus* in every shade of purple (there are scarcely any yellow ones) growing literally in hundreds of thousands. We have no record of when the roots were originally planted (and the oldest people about the estate say they have always been the same as far as their recollection goes); but they grow so thickly that it is quite impossible to step where they are without treading on two or three flowers. The effect produced by them in spring is magnificent, but unfortunately, their beauty is but short-lived. I have transplanted a good many roots to the wild garden to the great improvement of the size of the individual blooms; they are so matted together in the shrubberies I have mentioned, and have remained so long in the same place that the flowers are small. We have also great quantities of Primroses of every colour, from dark crimson to white, including every intermediate shade, owing to their having been crossed and re-crossed through natural agencies. These were probably planted at the same time as the *Crocuses* and Snowdrops, and the result is a most pleasing and very uncommon spring garden. When their beauty is on the wane they are succeeded by glorious varieties of Daffodil, principally the fine old double kind.

I may add that only those who have grown bulbs (particularly spring ones) among Grass have really seen them in perfection. Of course, spring bulbs look well in any position, whether in lines or patches in the flower-beds, but they are incomparably superior when seen peeping in irregular clumps from amongst dwarf vegetation. When once the flush of bloom has passed, the decaying leaves and stems are unnoticed in such spots as these, whereas in the garden properly so-called they are most unsightly, for what can look worse than tufts of *Crocus* leaves tied up (as they often are) in the form of brown wisps? pend upon it, the less artificial the style of gardening the more pleasure it gives, and my great ambition in the wild garden is to produce a result similar to what Nature would do if left to her own devices. Only those who have tried to imitate her graceful irregularity can tell (unfortunately) how far our best efforts fall short of her most ordinary productions. OXON.

VALUE OF HERBACEOUS BORDERS.

THOSE who do not possess a good mixed herbaceous border should lose no time in forming one in some suitable situation, as the best season for planting it is now at hand. A suitable site for such a border may generally be found without encroaching on the flower garden properly so-called. Borders hitherto devoted to the ribbon style of planting may easily be converted into mixed borders, and with good results, inasmuch as such a border always yields something for the flower basket, as well as forms an object of interest in itself from early spring till late in autumn, and, indeed, throughout the year, for the last fiery spike of the *Tritoma* will have scarcely faded before the Christmas Rose is unfolding its blossoms, and these are quickly followed by *Aconites* and *Hepaticas* in continuous succession, which, if they do not rival bedding plants in brilliancy of colour at any one time, are at least free from their faults. The mixed border, too, has a decided advantage in point of fragrance; for in it *Roses*, *Cloves*, *Pinks*, *Musk*, and *Mignonette* find a suitable home, as do also hosts of other sweet-scented plants. Neither can any plant, whether annual, biennial, bulbous, or bedding, be considered out of place in it, nor is one obliged to get up a stock of any particular kind of plant before placing it in its permanent quarters. Moreover, many plants enjoy being left for years undisturbed, a luxury which bedding plants can never experience. Compare, for instance, the growth of *Tulips*, *Hyacinths*, *Crocuses*, and similar plants that may be fortunate enough to find a home in the mixed border with that of those that are torn up with foliage half matured to make room for summer bedding plants. The difference between the two will at once be obvious, to say nothing of impairing their vitality through exposure during the hottest months of the year. That splendid autumnal flower, the *Gladiolus*, if left permanently in the ground, is always much better than when lifted and re-planted. There is also a host of plants that are not adapted for bedding out in any department that one scarcely knows what to do with unless a mixed border is available. *Phloxes*, *Lilies*, and *Carnations*, for example, all look better singly than when arranged in separate beds, as they often are in botanic gardens. There is no necessity for allowing strong rooting plants to overgrow their weaker neighbours, or self-sown seedlings to give the mixed border the aspect of a wilderness; but the pruning, training, and, above all, the digging practised in the mixed border should be done with care and judgment. If well prepared at first, a good surface-dressing of well-decayed manure or mould applied annually will suffice to keep it in good condition, until it will be found desirable to lift and re-arrange the whole of its contents. JAMES GROOM.

Henham.

An Effective Plant Stand.—At the house of a friend, a short time since, an arrangement of plants in an ornamental stand attracted my attention as being most effective and elegant, and the stand itself was anything but an expensive one, being of wire in the form of a circular table, with perforated balcony or edging round the margin; the table stood on supports about 3 ft. high, and underneath, about 6 in. from the ground, has an ornamental case for a pot plant. The edging of the table and pot case, if I may so term it, were gilt,

and all the other parts were painted white; the pot receptacle and edging of the table were lined with zinc, also painted white, against which the gilt lattice-work came out well. The flower arrangement of the ornamental pot case consisted of a well-grown plant of *Adiantum cuneatum*, and the table or tazza had an outer circle of plants formed of white *Primulas* and *Isolepis gracilis* placed alternately; inside of these was another circle of a higher growth, consisting of mixed varieties of Ferns, while the centre was finished off by a *Cactus* (elevated), whose magenta flowers had a most charming effect. This form of stand could be quite as effectively fitted up with other plants as those enumerated above, but, just at this season, arranged, as I have described, it looked very neat and pretty. Lilies of the Valley could be introduced in place of some of the pots of *Primulas*.
—ANNIE HASSARD.

ROYAL HORTICULTURAL SOCIETY.

At the adjourned anniversary meeting of this Society, held at South Kensington, on Thursday last, the 10th inst., the annual report of the Council for the past year was adopted by a large majority, after a warm discussion on the part of both horticulturists and resident Fellows. The accountants' report shows a balance in favour of the Society of £850 10s. 2d. It was, however, pointed out that this favourable result is mainly produced by crediting revenue with £786 16s., being the proportion for the year chargeable (under agreement with the Royal Commissioners) to the Life Composition Account. The actual result of the transactions of the year is therefore (after crediting revenue with £207 18s. on account of annual subscriptions in arrear) a balance in favour of the Society of £63 14s. 2d. This result, however, compares favourably with that of 1874, as in that year, after crediting revenue with £790 6s., proportion of Life Composition Account, there was a balance against the Society of £223 15s. 3d. Since completing the balance sheet and account the assistant secretary has reported that there are still some items, amounting to about £100 (the accounts for which had not been sent in) to be charged to the debit of revenue, which must be taken into account in considering the balance in favour of the Society.

Report from Chiswick.

The Board of Direction at Chiswick report that a great deal of good and important work has been carried on during the past season. That the crops of fruit have been plentiful, but owing to the great want of sunlight and extreme moisture, not only has the flavour been very inferior, but many varieties have decayed prematurely, an observation which seems to apply very generally throughout the country. The matter of the greatest interest which came before the Board, as regards the Fruit and Vegetable department, after the adjudication with respect to the trials of Onions, Celeries, and the more perfect definition of the several varieties of Currants, of which the Society possess a very complete collection, is the discovery, which has so long been a desideratum, of the resting-spores of the *Peronospora*, to which the formidable Potato murrain is due. Some peculiar features soon manifested themselves in a large collection of American varieties of Potato, which are under experiment. It was not, indeed, the first time that these features had been observed, for they were well known to Mr. Barron, who had remarked that they were far more pronounced with respect to English-grown sorts, than those which were immediately imported from America. Indeed, these latter seemed free from disease. During the early part of this year the disease was so prominent, not only in the garden, but generally over the country, as to call more general attention to the subject. It was, indeed, intimated that the matter was exaggerated, or indeed was altogether denied; but the slightest inspection showed that there was enough for serious inquiry. Some peculiar bodies had been observed in the blackened leaves, which were supposed to belong to some species of Protomyces, but Mr. Worthington Smith at once conceived that they might be the long sought resting-spores, and carried out the matter so perseveringly that he arrived at complete certainty on the question. It remains only to be observed how these resting-spores may comport themselves when germinating in the spring, and we trust that Mr. Smith will add to the honours, which he has so well merited, that of ascertaining this closing point in the life history of this destructive pest. The crop of fruit of all kinds has been unusually abundant in the garden this year, and many varieties which have not hitherto fruited have been observed, and descriptions of them have been made. An opportunity has also been afforded for correcting erroneous nomenclature and of ascertaining synonyms. The varieties of Currants have for many years been very much misunderstood, great confusion having existed as to their nomenclature and identification. A collection of as many kinds as it was possible to obtain, both at home and abroad, was secured, and the number of reputed kinds planted in the garden

amounted to 50. When these were examined, and compared one with the other, it was found that there were only 16 distinct—12 of them being red, 1 flesh-coloured, and 3 white. One of the largest experimental trials of Onions which has ever been undertaken was carried out very successfully. 153 samples were sown under 93 different names. These were all carefully compared and referred to their proper sections, whereby that large collection of reputed varieties was reduced to 20. A full report of this trial has been already published (see p. 20), and as this was confined to the spring-sown sorts, the remainder, consisting of the Tripoli and Silver-skinned sections, are now under trial as autumn-sown Onions, and will form the substance of a future report. A trial of all the varieties of Celery was also very successful, and out of 47 sorts that were sown, 20 proved to be distinct. A full report of this trial has also been published (see p. 94). An attempt was made to obtain a full report on the numerous varieties of the Kidney Bean, but the season being cold and ungenial this proved a failure, and another trial will be made this year. An attempt was also made to investigate those varieties of Potatoes that had not been included in the former trials, but the virulent attack of the Potato disease to which they were subjected rendered the experiment a failure. A complete collection of all known varieties of *Canliflower* has been sown for trial during the present season. It was found that the Potato disease this year attacked chiefly the new American varieties, grown from home-grown seed of the second year after their introduction; and it has been further remarked that all those New American Potatoes which produce such enormous crops from newly imported seed rapidly degenerate year by year after their introduction, and that the produce gradually becomes smaller and of inferior quality. The extensive collection of Strawberries which was planted for the purposes of trial, promises to fruit well this season. During the spring months the Floral Committee examined the collection of Bedding Violas which Mr. Barron had got together, consisting of some eighty-two varieties, and amongst them seventeen certificates of merit were distributed. Later on, a collection of *Fuchsias*, grown alike, in comparatively small pots, and consisting of 125 varieties, underwent the scrutiny of the same body, and on this occasion twenty certificates were awarded. These were cultivated under glass. In the open-air beds, a large contribution of Zonal Pelargoniums, from the principal nurserymen and florists, and consisting of 350 varieties, was planted out, and amongst them seventeen certificates were distributed. Besides these subjects, considerable collections of *Phloxes* and of *Pentstemons* were planted for inspection and comparison. The plants prepared at Chiswick for the decoration of the Garden at South Kensington always draw heavily on the labour and other resources of that establishment. During the past year there have been provided in this way, and devoted to this object, 12,000 flowering plants for the ornamentation of the Conservatory, and 52,000 for bedding out in the Garden. The Conservatory Plants, calculated at the low price of 1s. each, give a return of £597 16s.; and the Bedding Plants, valued at from 1d. to 4d. each, a return of £457 17s., making a total of £1055 13s.; the whole expenditure on maintaining the Garden during the past year being only about £1500.

Skating "Rink" at South Kensington.

A correspondent of the "Times" has had something to say about the latest efforts of the Society to prolong its existence by means of a skating rink. "A Guarantor of the Exhibition of 1851" thinks a "rink" has nothing to do with the science and art of horticulture. The promoters of this idea, being men of "serious" views, seem unaware that the ruined foundations of a "rink" now disfigure the south end of the gardens at South Kensington. Lord Bury and Sir Alfred Slade's Council began a "rink" last year, but being threatened by an injunction from Her Majesty's Commissioners (the trustees of the estate), it was abandoned. The Commissioners holding, for the benefit of science and art, the gardens of the value, according to present prices, of more than a million of pounds sterling, have thought it consistent with their public trust, to allow the lease to be virtually forfeited for many years by non-payment of rent; to allow the gardens and buildings to be neglected, to keep the public out of the use of the ground, and to become guarantors for the debts of the Society; but it is to be hoped that they will not delay the inevitable crisis by recanting their objections to a "rink." It has been demonstrated that the lease to the Horticultural Society is unworkable and a failure, and it appears to be the duty of the Commissioners to awaken to a perception of this fact, and rouse themselves to a sense of the responsibility that they hold the ground at Kensington as public trustees, bound to administer it for the benefit of science and art, or, if unable to do so, to surrender it to the public. A correspondent of the "Pall Mall Gazette," writing on the same subject, says—The Commissioners of the Exhibition of 1851 are the

owners of the large and valuable piece of ground at present leased to the Royal Horticultural Society. The land was bought out of the surplus profits of the first International Exhibition; and as the money was contributed by the visitors to the Exhibition, who cannot be identified and have left no representatives, it must now be considered as in the nature of public property. It was supposed that the encouragement of the science of horticulture came sufficiently within the objects to which public property might fairly be applied; and in this belief the Commissioners leased the land to the Royal Horticultural Society at a rent which, estimated by the present value of the site, must be called nominal. For some years this rent has become nominal in another sense, inasmuch as it has not been paid. It is notorious that from the standpoint of scientific horticulture the Society is a failure. The gardens have latterly been maintained for the benefit of the residents in Queen's Gate, Prince's Gardens, and Cromwell Road, with the interposition of occasional flower shows, which were useful partly as bringing in a little money, and partly as helping to drape the unpleasant fact that the Society was doing next to nothing to promote the object for which it professedly exists. Last year the Society became so nearly insolvent that it could not pay the prizes for which it had invited competition; and the result was that at one of its flower shows there were as good as no exhibitors. The cause of this catastrophe is not far to seek. The Society appeals to two classes of persons—horticulturists, for whom it does nothing; and the residents in the streets immediately round the gardens, for whom, considering what they pay, it does a great deal too much. In the administration of the Society the interests of the former class have been sacrificed to those of the latter; and the consequence is that horticulturists generally have grown indifferent to the Society's misfortunes, while the residents in South Kensington, though far from indifferent to them, are not at all disposed to put their hands in their pockets to better them. It must be remembered, however, that if this section of the Society's fellows were prepared to pay ten or twenty guineas a year instead of four guineas, and if by this means the Society could be set on a sound footing financially, the matter would not be ended. The Commissioners of the Exhibition are a public body, holding land bought by what is in effect public money in trust for a few wealthy families who want a quiet lounge for themselves on Sundays and a safe playground for their children on week days. The ground was originally let to the Society in its supposed character as a promoter of horticulture. That element in it has all along been choked by the residential element, and would probably be entirely banished by its further development. Yet a further development of the residential element is the Society's only chance of getting once more on its legs. So that the Society finds itself confronted by its dilemma. The only way in which its income can be raised so as to pay even the present nominal rent is by making the gardens more attractive to, and by consequence more entirely the possession of, the occupiers of a few houses in a fashionable district; while in proportion as this object is attained so it becomes more obviously the duty of the Commissioners to whom the land belongs either to give the Society notice to quit or to insist upon a rent which shall fairly represent the real value of the land leased to them. The writer of the letter in the "Times" estimates that the ground held by the Society is now worth more than £1,000,000, and supposing that to be within the mark, we put it at half this sum, it is plain that a rent of £5000, which we believe is what the Society is under a consistently broken agreement to pay, falls very far short of the real value. If the occupiers of the houses round the gardens like to call themselves the Royal Horticultural Society, and are willing to pay the Commissioners a fair rent for the land they wish to have the use of, we do not know that there would be any objection to the granting of a new lease. The ground would no longer be let below its value for the promotion of an imaginary horticulture, and the Commissioners would draw from it a large yearly income which they might apply to the purposes of their trust. The only thing that is clear is that they ought not any longer to be parties to a gross misuse of public property. A body of Commissioners charged with the duty of administering an estate in the interests of science and art has no right to leave the land in the occupation of a Society which has virtually ceased to have any scientific or artistic character, and has for years been unable to pay even the nominal rent demanded of it. Why should the inhabitants of two or three terraces in South Kensington have any special claim on the Commissioners' bounty? The inhabitants of every London square contrive to maintain gardens for the use of their nurseries without help from the public; and if the residents in Queen's Gate cannot be content with having Hyde Park and Kensington Gardens close to their doors, they must pay for what they want in addition, just like other people. That they should be charged a fair rent for the gardens is not the best arrangements that could be made, but it is at

all events free from the glaring faults of the present arrangement. It would be better still, however, if the land itself, and not merely the money derived from letting it, were restored to the public. It might very well be turned to account in providing a site for some of the great national collections which are constantly tending to outgrow the confined space at present allotted to them; or by the sale of a small portion the Commissioners would be able to raise funds sufficient to maintain the rest as a botanic garden to which students should have free admission. As an adjunct to Kew, the ground would probably do more good to science in a fortnight than, in the possession of the Horticultural Society, it has done in fourteen years. At all events, public land supposed to be worth a million or even half a million of money ought not to be wasted as it now is; and if the Commissioners do not act with promptitude and decision, their lagging steps should be quickened by parliamentary interference.

BERRY-BEARING AUCUBAS.

I HAVE a row of Aucubas, 45 ft. in length, the plants in which are 5 ft. in height; in the centre is a male Aucuba, by means of which the whole of the plants in the row are beautifully set with berries without having recourse to artificial fertilisation—a fact which shows how readily Aucubas produce berries through a natural distribution of the pollen: some of the berries are now colouring. From these plants I have raised different batches of seedlings, the first of which are now from 2 to 3 ft. high, and are bearing berries freely. Fully 80 per cent. of the seedlings have green foliage; the male plants are easily distinguished by the points of the flowering shoots being much larger than those of the female plants. I allow the berries to remain on the plants as long as possible; they drop freely towards the end of May, when I gather them, and in a short time afterwards sow them in a seed-pan, and place them on a shelf in the stove, where they soon germinate and make good plants, about 3 in. high, the same season. In the following spring I put them off into 3-in. pots, and plunge them out-of-doors.

JOHN GARLAND.

Killerton, Eweter.

Allow me to add a few words to my former communication on berry-bearing Aucubas (see p. 117). I there stated that a small male Aucuba (some 8 or 10 in. high) had fertilised half-a-dozen female plants at various distances apart in a small garden. I now find that the pollen must have found its way into an adjoining plot, which is separated from the other by a high, closely boarded fence, as a female plant on the opposite side of the fence is now sprinkled all over with berries. This plant is between 30 and 40 ft. distant from the place where the male plant stands.

G. G.

Notts.

Gardening in a natural way does not seem to suit some people; they must have elevated boxes, grafting, budding, and many other systems strictly artificial of inducing the Aucuba to bear berries. Has no one ever considered at how small an expense male Aucubas may be procured and planted amongst female plants? The male Aucuba cannot be too much planted, particularly where there is, as in most places, a redundancy of the opposite sex. The first time I ever saw pots elevated was at St. Cloud, where the superintendent of the Imperial gardens showed me a house where he adopted this plan, in order to put berries on his Aucubas. It is not, however, the best plan, although I tried it five years ago in the open air and with satisfactory results. I have also tried budding, but to very little purpose, comparatively speaking. Any one who will buy male plants will be delighted with the results next year. With the green kind (*A. viridis*) I have succeeded best.—W. MELLES, *Camden Road*. [Mr. Geo. Paul, to whom we are indebted for this note, says, "I never saw Aucubas more loaded with berries than Mr. Melles's. They range from 6 ft. to 8 ft. in height, and as much through, and when the fruit is ripe must be strikingly effective."]

The Ochra as a Fibre.—This plant, though indigenous to the West Indies, has long been naturalised in India. Its pods produce the common vegetable known as Ochra by the English, Gonto by the French, Chimtomto by the Spanish, and Benditeai in India, where it is so much esteemed for its mucilaginous thickening for soups. The pods are gathered green and pickled like Capers. The seeds may be boiled like Barley, and the mucilaginous matter they contain is both a demulcent and emollient. They have also been recommended when roasted as a substitute for Coffee. A patent has now been taken out in France for making paper from the fibre, and for this purpose it is to be introduced into Algeria. The fibre is prepared solely by mechanical means in a current of water, without any bleaching agent, and the pulp, washed and bleached, is reported to make a strong, handsome paper, equaling that from pure rags. It is called *banda paper*.

NOTES OF THE WEEK.

— A bush of *Aucuba japonica*, measuring 60 ft. in circumference and 12 ft. in height, and literally covered with scarlet berries, now forms a most beautiful object in the gardens at Marlfield, near Clonmel, County Tipperary, the residence of Mr. and the Honourable Mrs. Bagwell, and is the admiration of every one who sees it.

— ONE of the best cooking Apples now in Covent Garden is Lucombe's Seedling. It is also known in the Apple market as the Mushroom Apple and Yorkshire Greening. It is sent to the London market from Kentish orchards, and it was originally raised in Lucombe & Pince's nursery at Exeter.

— It may be useful to some of our readers having much foreign correspondence to know that letters and documents in all languages are translated into English or *vice versa* at the Universal Translations Institute, 59, Mark Lane, London, the proprietor of which, Mr. Ernest Bergman, is the son of Mr. F. Bergman, the well-known superintendent of Baron Rothschild's beautiful gardens and estate at Ferrières. This Institute was established in 1868, and efficiently meets a public want.

— THE new street from Trafalgar Square to the Thames Embankment will now be opened in a few weeks. It is to be planted on either side with trees, like the Embankment itself. Meanwhile the Board of Works is pushing on with a new thoroughfare connecting the east of London with the west, and extending from Bethnal Green to Bayswater. It will sweep away a good many of the worst of the metropolitan rookeries, and as it is to be several miles in length, the cost of its construction is likely to be very considerable. It is to be hoped that the opportunities for tree-planting thus offered will be wisely taken advantage of. It is also greatly to be desired that the Board would encourage the planting of the proper trees in the many open roads and streets now bare of them. Mr. Meston, or whoever has charge of the planting, will, we trust, give us some variety in the trees; "always Plane" is better than always bricks, but far from being the best course even with our present knowledge of the trees that grow in cities and the injurious atmospheres therein.

— MR. S. HIBBERD lectured at the Society of Arts last Wednesday evening, on the pruning and management of fruit trees. The lecture, which had the merits of clearness and vigour of exposition, was a denunciation of pruning, and a plea for leaving the trees to Nature. No doubt much harm has been wrought by overpruning of diminutive trees, but the lecturer was fighting against facts, common sense, and the best practice, in going too much the other way. It is demonstrable that all the finest fruits in every fruit market in Europe and North America are from carefully pruned trees. The difference between the rubbish of the neglected orchard that is not worth sending to market, or which, if sent there, fails to pay for being gathered, and the finest fruit which brings an abundant return to the grower and all concerned in its production, is mainly caused by the neglect of judicious pruning. But judicious pruning is not mutilation, and if Mr. Hibberd had confined himself to denouncing that, nobody could object. The lecturer also spoke against dwarfing stocks, which are, notwithstanding, the greatest improvements ever introduced into our hardy fruit culture! A few years more will probably show this to everybody interested in the matter; what the French Paradise may do, not merely for the amateur but for the large grower for market, has been already proved in this country. Mr. Dancer, of Little Sutton, who is probably the most successful of London market fruit growers, has already over 400 of Cox's Orange Pippin alone on it, and they have already borne the finest fruit freely; and the other dwarfing stocks have each peculiar merits, not the least of which is the great gain in time. This is so marked in the case of the French Paradise that little trees in Messrs. Veitch's nursery at Fulham were last autumn laden with fine fruit. This, indeed, was so plentiful that the crop would equal that often gathered from large trees occupying the same space.

— In a small cheap pamphlet on "The Potato Disease, by a Resident of Kent," we find the following recommendations as to its culture:—Have the land clean and in good condition from having well manured it for other crops; select two or three varieties of the early ripening sorts suitable to your soil and taste, for early and late consumption; plant in February or March—the plants will not be so liable to be injured by spring frosts on this plan, being longer in coming through the ground—according to the dryness of the ground, whole sets if possible (before the first shoots have pushed forth), about the size of a large hen's egg, 3 or 4 inches deep; cover them over to about a foot in height from the set, and do nothing more to them till they are ripe, except carefully hoeing or pulling out any weeds that may grow among them; when the haulm is quite dead, take the Potatoes up on a fine day and store them.

Giving Air in Forcing Houses.—Mr. W. Taylor has some pertinent remarks on this subject in the "Journal of Horticulture." "I will pass over," he says, "the question of high night temperature kept by artificial means, as I have reason to believe that is nearly a thing of the past. But what about giving air in the morning? Is it never given too late or too abundantly? Imagine a house with a temperature of 70° while the air outside is frosty. Fill the house with tobacco smoke and watch how very rapidly it all escapes through the smallest apertures. The air, I imagine, of the house changes in nearly as short a time as it takes the smoke to escape, and of course would change just as rapidly if there were no smoke there, the smoke only making the movement of the air visible. The greater the difference between internal and external temperatures the more rapidly will the air change in the house, and therefore the openings for ventilation ought to be regulated according to such difference. People are too much afraid of letting the sun help them to do their forcing; they neutralise its good effects by letting in a rush of cold air. We are getting better in this respect, but there is still room for much improvement. There must be more Nature-forcing; the more light the more heat and moisture should there be. Many people would be surprised at the amount of heat some plants will flourish in when they have sufficient sunlight and moisture, if they have not previously been drawn out too much with fire-heat during dull weather. Very often, instead of giving air on every favourable occasion as the old calendars recommend, it is better policy to shut up as close as possible when the sun shines in winter and early spring. This kind of forcing, however, requires more care and judgment than the old-fashioned way, but, at the same time, when properly done it is much more successful and far more economical. All the air a house is likely to require during any part of the day ought to be given before the sun has shown on that house half-an-hour, and before the thermometer has risen 5°, a little the instant touches it, a little more in a few minutes when the mercury is inclined to rise, and so on by degrees, till as much is given as former experience has taught to be necessary. I would much rather a man under my command remained in bed all day than that he should commence giving air after the sun has been shining on a house half-an-hour."

Plumbago capensis for Autumn and Winter Flowering.—Where large quantities of flowers are required in autumn and early in winter, this plant, says Mr. Henderson, of Thoresby, in the "Florist," from the distinct colour of its blossoms, and the easy way in which it can be had in great beauty, should be grown largely. In March put in a quantity of cuttings, which will root freely in a frame amongst ordinary cuttings. When well rooted, pot off singly into small pots, using rather a free compost, and re-placing them in a close, warm frame or pit, until they have taken root, when they ought to be removed to a house where the temperature ranges about 45° at night, with a rise during the day; as spring advances they will stand in a cold frame (say all May), keeping frost from them, and never letting them suffer either from want of water or of pot-room. When all danger from frost is past, select a good piece of ground, sheltered from rough winds, but fully exposed to the sun, and plant them out of their pots 18 in. apart. Here they will require little or no attention until near the end of September, except an occasional pinching, and if dry weather sets in, a few copious waterings. They should then be lifted carefully and potted into as small pots as the roots can be got into, watering them well, and standing them in a cold frame, kept close and shaded, if bright sun occurs, for about ten days, giving them an occasional sprinkle overhead with the syringe in the morning. If these plants be put into a gentle heat they will soon open their blooms, when, by transferring them to the greenhouse, they will be found very ornamental.

Suckers on Peach Tree Roots.—In pointing over a Peach-border a few days ago I came across numbers of suckers. I carefully removed the soil, and cut them clean out as close to the root as I could without injuring the latter. Perhaps some of your readers, who have had experience in this matter, will kindly explain whether suckers affect the bearing properties or not of the tree. I am inclined to think that one of the causes of so many suckers appearing is the fact, that as soon as they are seen they are constantly removed. In the operation the roots get bruised, partial stoppage in the flow of the sap occurs, and, as a consequence, buds are produced which otherwise would have remained dormant. These, I think, must deprive the tree of a good deal of nourishment which can ill be spared.—REX.

Hardy Climbers with Fine Foliage (Lady W.).—*Ampelopsis Veitchii*, *A. hederacea*, *Aristolochia Sipho*, *Hedera algeriensis*, *camariensis*, *palmaria*, and *himalaica*. There is a very elegant kind of *Cissus* at Messrs. Veitch's not yet sent out which has finely-cut leaves, and would be precious for such a purpose as you describe. *Lardizabala hibernica* is well suited for a wall, and has distinct and very ornamental foliage.

THE INDOOR GARDEN.

CELOSIAS FOR WINTER BLOOMING.

DURING the dull days of autumn and the yet more sombre winter season few plants are more striking than Celosias. For late blooming the seed should be sown in August, in light soil, and covered but slightly as the seeds are small; after sowing, place the pots or pans, as the case may be, in heat, and as soon as the plants are up raise them near the glass, as future success largely depends on a sturdy habit induced during the first stage of growth. Pot off as soon as the seedlings are large enough to handle, and plunge the pots in a bottom-heat of 60° or so, still keeping the plants near the glass. Under such treatment they will grow fast, and the pots will soon become full of roots, when successive shifts should be given until a 6 or 8-in. pot is reached. These sizes, unless very large plants be required for lofty conservatories, will be sufficient. Properly managed and well fed with manure, a 6-in. pot will be large enough for a Celosia a yard high and almost as much through. Large plants, however, are not by any means the best or most useful for winter decoration. Well-grown pyramids, about 2 ft. high in 6-in. pots, are much more serviceable, as they will stand on a shelf in any out-of-the-way part of the stove, and yield quantities of blossom which will prove useful in a cut state. After their final shift, Celosias should gradually be removed from a hot to a more temperate climate; a warm light greenhouse or conservatory is about the best situation for them. The final shift should be into rich soil, composed of turfy loam and leaf-mould, with a free admixture of sand. For summer decoration Celosias may have a much richer soil, say half of loam and half of rich manure. But less stimulating food is better for such as have to pass through the winter. The chief enemies of Celosias are thrips and red spider, both of which dislike moisture, in which Celosias delight while growing. Hence, if the plants be shaded and frequently syringed, such pests are seldom troublesome. Should they, however, gain a footing, fumigate twice at least in succession with Tobacco-paper, and, in fact, continue fumigating until they are eradicated. The pyramidal flower-spikes of Celosias have almost driven the old Cockscombs out of cultivation, and deservedly so; for though not without interest, they required a good deal of skill and care to grow them well, and they refused to group effectively with other plants: The crimson comb might be large and striking enough, but it never could be made anything else than stiff and formal, whereas these new Cockscombs, or Celosias, group well with all kinds of plants, and are among the most useful of any for cutting for vases or bouquets. Celosias in groups by themselves are very showy, and they have a still richer effect when mixed with such strikingly beautiful foliated plants as *Amarantus Henderi*, *A. salicifolius*, and *A. tricolor*. Of these feathered Celosias there are a great many varieties, ranging through the different shades of colours from lilac to crimson and from yellow to orange. Almost each grower has his own specially good strain, distinguished either by its superiority of vivid colouring, size, or profusion of bloom. Among the finer named sorts are the following:—*C. pyramidalis aurea*, golden; *C. p. ignea*, crimson; *C. p. aurantiaca*, orange; *C. p. plumosa aurantiaca*, variously coloured. One and all of these produce feathery-looking flowers of great richness and beauty. Indeed, few plants are more striking or more useful in the stove during the winter season, or more highly ornamental in pots in the conservatory throughout the autumnal months than these pyramidal Cockscombs.

Pyramidal Cockscomb (*Celosia pyramidalis*).

NOTES ON ORCHIDS BY A TEA-PLANTER.

SINCE I began cultivating Tea in Cachar, writes a correspondent in "The Gardener," I have noticed some very fine Orchids, such as *Dendrobiums* of different kinds, *Vanda teres*, *Colognyes*, *Cymbidiums*, *Saccolabiums*, and *Aerides*, the latter by the hundred, especially *A. odoratum* and *A. o. roseum*, and the observations I have made in reference to these lead me to think that the majority of East Indian Orchids at home are grown in too hot a temperature, especially in winter. If I had again to deal with Orchids in Great Britain, I would make my minimum in winter from 40° to 45° at night, and allow it to go up to 80° during the daytime, but only with sun-heat. After February the night temperature could be raised to 50°, that is to say, if the plants showed signs of starting. Here mostly all the Orchids flower during March, April, and May, and up to the latter month they do not make any leaves, owing to the want of moisture. The rains begin in June, and from then till the middle of September the plants are never dry, but in a soaking wet state; during this period they make their growths. The leaves on *Aerides*, *Vanda teres*, and others, are short and glossy, the plant short-jointed, and every leaf like a piece of lath as regards stiffness—a circumstance which I attribute to their having a good long rest, and also a low temperature when in that condition, during which time they are as dry as a bone. When they are well started into growth, water should be literally poured into them, and they should be kept in a steaming heat, but their drainage should be efficient. As regards soil, I would recommend good loam with rough charcoal mixed with it for all terrestrial Orchids. As respects those which are generally placed on blocks or in baskets, it cannot be denied that their natural habitat is on the trunks and branches of trees; but, at the same time, such situations are not those in which they flourish best. In April, 1873, I planted a large *Vanda teres* in the soil, at the root of a Cotton tree. This I did as an experiment, expecting to see it die. I put it 1 ft. into the soil, and trained its top to the tree. I paid little or no attention to it until about the following May (1874), when I went to see if it were still alive, and, to my surprise, I found nearly eighty spikes of bloom on it, and dozens of air-roots issuing from the plant about 1 ft. above the ground, creeping downwards and entering the soil instead of laying hold of the tree. I shortly afterwards earthed it up with loam about 18 in., and last May (1875) the bloom on it was really magnificent, and the plant is now in luxuriant health. Since May, 1874, I have planted *Dendrobiums* in soil alone, and they are thriving splendidly. For *Dendrobiums* I would advocate mixing the Sphagnum Moss with charcoal and round lumps of fibry loam, and especially let good drainage be provided. The quickest method I have tried for fixing Orchids to posts is to spread a layer of cow-manure round the post, cover it with a piece of old blanket, and then tie the plant firmly on it.

RAISING FLORISTS' FLOWERS FROM SEED.

The first essential point is to secure seed saved from the finest flowers of the finest kinds, the chances of success being vastly greater from a few plants raised from seed of the finest quality than from a large quantity raised from seed of an inferior description. It is from seed only that new varieties are raised, and this can be done as successfully by the inexperienced amateur as the professional cultivator—in fact, many, if not most, of the finest florists' flowers now in cultivation have been raised by amateurs.

Antirrhinums.—Seeds of these should be sown in February in a cool frame or under a hand-light, and from March to August in the open air. Sow thinly, and, as soon as the plants are strong enough, transfer them to beds or borders as required. This useful perennial blooms the first season if sown early, and produces a great variety from seed.

Auriculas.—These should be sown from February to the end of April in well-drained pots or pans. Use a compost of about two parts loam and one part leaf-soil. Cover the seeds very slightly, and place them in a cool pit or under a hand-light in a shady situation—a north or east window will answer the purpose. As soon as

the plants are large enough to handle, pot them off into small pots, and keep them under glass in a shady situation, giving plenty of air. When these pots have become filled with roots, finally pot off for flowering into 5-in. pots, with the addition of a small quantity of well-decayed cow-manure to the soil. *Arucula* seed may also be sown in a shady situation in the open ground during summer, and kept well watered until the plants are up.

Calceolarias.—Seeds of these should be sown in July and August in well-drained pots or seed-pans; cover the drainage with rough, fibrous loam, and fill up to the surface with fine, light, sifted mould and silver sand; water with a fine-rose water-pot, after which sow the seed, placing a piece of glass over the pot to retain the moisture, no covering of soil being required. Place the pots in a cold frame or under a hand-light, taking care to shade from the sun. Remove the piece of glass as soon as the plants are up, and when large enough to handle, prick them off 1 in. apart into pots or pans made up as before; place them in a somewhat close situation, and when of sufficient size, pot them off singly, and treat them as recommended for tender annuals.

Carnations, Picotees, and Pinks.—These may be easily raised by sowing thinly from the early part of May to the end of July, in shallow drills in the open air in a somewhat shady situation; keep them well watered until the plants are up. Plant them out in autumn where they are intended to flower, 1 ft. or 18 in. apart.

Cinerarias.—When required for early spring flowering, these should be sown in July and August, and for autumn and winter decoration in March, April, and May, in pots and pans. The seed should have out a slight covering of soil. Place the pots in a cold frame or under a hand-light. Shade from sunshine. Pot off when the seedlings are large enough, and treat them as tender annuals. They may also be successfully raised in June, July, and August, sown under a hand-light, or in a moist, shady situation in the open air, taking care to pot them up in September, and to remove them to a place secure from frost.

Chrysanthemums.—Both large-flowered and pomponne kinds when raised early will bloom the first season. Sow in March in a slight bottom-heat, or in April, May, and June in a shady situation in the open air. Prick out on nursery beds when the seedlings are about an inch high, and when strong enough plant them out where they are intended to flower. *Chrysanthemums* like a warm, sunny situation, and an abundance of moisture.

Dahlias.—Sow from March to April in pots or pans on a slight bottom-heat, and when the young plants are about 2 in. high, pot them off singly into small pots, and place them in a cool frame or under a hand-light, gradually hardening them off till the end of May, when they may be transferred to the open air, giving them a slight protection for a few nights, if the weather be cold. Thus treated, Dahlias will bloom the first year from seed.

Fuchsias.—These should be sown from February to May in pots on a gentle bottom-heat. When about 2 in. high pot them off into small pots, shifting them into larger-sized ones as these become filled with roots; treat them afterwards as ordinary pot plants.

Geraniums.—Gold and silver tricolor, bronze, and zonal kinds, should be sown in February or March in well-drained pots, pans, or boxes, and placed in a gentle heat. These, when grown freely, will bloom the first year; but they may be easily and successfully raised in pots in sunny windows, or in a cool frame without bottom-heat, any time from April to the end of August; pot off singly into small pots when the plants have pushed a second or third leaf, and, in order to induce sturdy, compact growth, place them in a position where they will obtain all the air and sunlight possible. It may be observed that seed from the most carefully hybridised flowers will not produce a large per-centage of variegated seedlings, and that the beautiful variegations for which the gold and silver tricolor varieties are celebrated are not always shown by the plants in a young state, but are frequently produced by sports, breaks, or side-shoots, which are removed and struck as ordinary cuttings any time during the summer.

Hollyhocks.—These should be sown thinly in seed-pans in February and March, under glass, or in shallow drills in the open air from April to July. Select a shady situation, keep the young plants free from weeds, and plant them out in autumn or early spring in clumps, beds, or rows.

Pansies and Polyanthuses.—These should be sown from March to August in shallow drills in the open air, selecting a moist, shady situation for them. Plant them out as soon as large enough to handle, 9 in. apart in beds. Pansies sown in March will bloom the following autumn; those sown in August, the following May.

Primulas.—These should be sown in March, April, May, June, and July. Great care must be taken to have a well-drained pot or seed-pan filled to within $\frac{1}{2}$ inch of the top with sifted leaf-mould;

leave the surface rather rough, and sprinkle the seeds thinly upon it. The most successful raisers do not cover with soil, but place a square of ground white-washed glass over the pot. Place them in a warm house or hot-bed, and, when the soil becomes dry, water them very gently. The seed will germinate in two or three weeks, after which remove the glass and keep them in a shady place. Pot off into small pots when the plants are $\frac{1}{2}$ inch aboveground, and place them near the glass in a frame, greenhouse, or window.

Verbenas.—Sow these in February or March in pots, and place in a pit or frame on a slight bottom-heat, or in April and May in a warm, sunny window. Pot them off singly into small pots when about 1 in. high, and plant them out the second week in May, in beds or borders where they are intended to flower.

Norwich.

G. DANIELS.

Rhododendron argenteum.—M. Ambrose Balfe informs us that specimens of a fine variety of this *Rhododendron* are now in bloom in the Royal Botanic Gardens, Glasnevin. In its native country *R. argenteum* forms quite a tree 30 ft. in height or more, and bears gorgeous flower-heads, which are very large, as are also the individual flowers. The head, in fact, consists of several tiers of flowers, each resting horizontally on the one below. The flowers are pink in the bud state, but as they expand become white. Each flower shows at the bottom of the great open tube a rich dark purple spot encircling the base of the stamens; this is very conspicuous by reason of the way in which the flowers present themselves to a front view. The clusters of anthers with their purple stamens add much also to the effect; but of all the floral organs the stigma is the most striking on account of its great size and bright rosy-carmine colour. There are, moreover, several other choice Indian *Rhododendrons* in flower at Glasnevin just now, and among them one which, as regards symmetrical compact heads and fiery brilliancy of colour, has no equal, namely, *R. barbatum*.

Want of Chlorophyll in Variegated Seedlings.—Mr. Gumbleton's note on this subject (see p. 116) is very interesting, and since want of chlorophyll or deficient root-action (or both combined, inasmuch as each depends on the other) is the cause of death, it has occurred to me that grafting or inarching might often, in such cases, be resorted to with success. A clever manipulator, with a sharp knife and a few strands of soft cotton, might inarch a green or partially green seedling on the yellow ones, more especially if a green spot can be found on the stem of the seedling which shows too great a predominance of yellow. In less extreme cases, that is, where there is rather more chlorophyll, the young seedling might be grafted on a young cutting or branch of an old plant as a stock. This might be practicable in the case of variegated *Acer*s, *Pelargoniums*, *Aralias*, &c., but of course not in that of endogenous plants like *Phorium*. It does not appear to be sufficiently known that many plants are more easily grafted when very young, that is, when all their tissues are in a soft or cellular condition, than at any other time. Major Trevor Clarke succeeded in grafting a seedling *Cotton* below the seed-leaf on to an older plant as a stock; and it was at one time a common practice among Italian gardeners to inarch two or three seedling *Oranges* together and afterwards to sell the plants in pots as curiosities; indeed, the *Trifacial Orange* is said to have originated in this way, but of this we have no proof. Whether inarching or grafting be useful or not in the case of variegated seedlings which are deficient in chlorophyll, or, in other words, wanting in health and vigour, the fact remains that young growing tissues are the only ones which unite properly in grafting; hence it follows that a perfect union by grafting can only be obtained when both scion and stock are in a cellular condition, that is, while the cells are growing and before the vascular tissues begin to harden.—B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Single Hyacinths Best for Forcing.—It is worth reminding beginners that single *Hyacinths* only should be forced early—double ones do no good. We have had fine plants of single ones since Christmas.—CHIEF.

Wintering Alternantheras.—During two years these died off with me in winter—a loss to check which I tried a variety of means, but none so effectual as the one I have tried this season. When I took them out of the beds last October, I put them thickly together in the bed of my Cucumber-house. Here they have kept splendidly, and to-day (Feb. 7) I am tearing them to pieces and putting in the cuttings.—P.

Speedy Way of Striking Cuttings.—I saw in a neighbouring nursery the other day a mode of propagating soft-wooded bedding plants, such as *Verbena* and *Lobelia*, which might be usefully followed. All along the pipes employed for top-heat, by the side of the central pathway, were placed zinc pans, $\frac{3}{4}$ in. deep, and from 6 to 7 in. wide; these were filled with 2 in. of silver sand, kept wet through. In this were inserted the cuttings, which, under such conditions, are said to strike root with great rapidity.—N. H. F.

THE FRUIT GARDEN.

GRAPES IN GREENHOUSES.

By paying attention to a few common-place particulars, Grapes may be cultivated in greenhouses with a very fair amount of success. The aspect of the house is not of great importance so long as the principal exposure is not direct north. Supposing a span-roofed house to run north and south, the best side on which to plant the Vines would be the east. In houses in which plants are grown in the centre, it is not advisable to plant Vines on both sides of them, and by planting them on the side least exposed to the sun, their shade has no weakening influence on the plants. The main rafters in small houses are generally 6 or 7 ft. apart, and on each of these one Vine should be planted. Three wires should be fixed for the support of each Vine. The centre one should run up underneath the rafter, and the other two should be fixed one on each side a foot distant from the centre one. An arrangement of this kind leaves 4 ft. of vacant or uncovered space between each Vine. The wires should be placed 15 in. from the glass, a distance at which they may be secured by means of a three-armed support screwed into the wood. There should never be more than one leading cane taken from the root, and this should be trained to the centre wire. As the side-shoots grow they should be carefully tied to the side wires, and attention must be paid to the stopping of the shoots, as on this depends, in a great measure, the success of the undertaking. Each shoot should be stopped, and not allowed to grow another inch further than one leaf beyond the bunch. On short-jointed wood the fruit will generally be produced from 6 to 9 in. from the main rod, and by restricting the shoots as just directed, the leaves and young wood will not extend much beyond the outside wire. In the case of young Vines there should be no hurry in getting them to the top of the house. The first matter requiring attention is the border, and for this I

will not say that so many cart-loads of the best turfy loam are absolutely indispensable—as hundreds who grow, or might grow, Grapes in greenhouses have no great choice of soil—but, if it could be got, all the better. Many fairly good Grapes are, however, grown in common garden soil, and often in no prepared border whatever. Underneath the side shelves is where the Vines are generally planted, and there the earth should be taken out to the depth of 3½ ft. The opening thus made should be at least as broad as it is deep, and if it can be made wider so much the better; but about many small houses there is not space enough to admit of making a large border. In preparing material in which to plant the Vines, a quantity of the best soil obtainable should be procured. If nothing else can be had, use that in which ordinary kitchen garden crops have been grown, adding to it parings of Grass verges, road-scrappings in which there are horse-droppings, plaster rubbish, and bones broken small. These should all be well mixed together. 6 in. of rough stones or bricks should be placed at the bottom of the border for drainage, and over that the soil removed. The mixture just adverted to should then be put moderately firm above this, and the whole should be allowed to settle for a week or two before planting the Vines. The next thing to be considered is what varieties should be planted—not at all a difficult problem to solve. Amongst black kinds the Black Hamburgh should be invariably preferred, inasmuch as there is no other that succeeds in a cool house, and, under ordinary treatment, so well. It is a free grower, sure bearer, and its fruit, unless under very exceptional circumstances, is always well flavoured. From among white varieties select Royal Muscadine or Chasselas de Fontainebleau of the French, a kind which seldom fails

where the Hamburgh succeeds, and it is a kind that is easily grown. Its fruit is somewhat small, but its flavour is good; and there is no certainty that such kinds as Muscats will succeed in a greenhouse. Neither should late varieties be grown in such a place. The fruit of these does tolerably well while it is young, but it fails as it approaches maturity; a remark that applies to such sorts as Lady Downes, Black Alicante, and Gros Colman. With only two kinds there is certainly little variety, but it is better to grow two sorts well than a great many indifferently. Well-ripened canes should be selected for planting, for, where such are chosen, they start into growth under the every-day conditions of the house: and the growth, made under such circumstances, gets hardened as it proceeds; whereas a Vine that has been brought into leaf in strong heat, and planted in a greenhouse, would have to overcome a double check in the shift and change of temperature to which it would be subjected. About the beginning of March is a very suitable time to plant, using Vines raised from eyes, and grown into well-ripened canes the previous season. The loose soil should be shaken from their roots, and those which have grown in a circular direction should be uncouiled. In planting, make a hole large enough to accommodate the roots comfortably; and the soil should be laid over each root with the hand until all are covered, when the surface may be trodden down and dressed up with a spade, watering well with tepid water. There will be little signs of growth until after they have been planted two or three weeks, and no extra heat should be applied in order to induce them to start quickly. When the buds are bursting, the ventilators may be partially

closed on cold nights, but a cool temperature and short-jointed wood are better than a warm one and feeble growth. If the canes are—say 6 or 7 ft. in length—they should be cut back when planted to 2 ft. from the bottom, and only three of the buds left should be allowed to grow, each shoot produced by them having a wire to itself. These may be allowed to grow to the top of the house. When pruned in autumn the two side-roads should be cut away, and

the centre one alone retained with 2 or 3 ft. more of young wood than it started with at the beginning of the season. This young wood left will throw out several side-shoots when started the following season. Two bunches may be allowed to remain on the strongest side-shoots, none of which should extend beyond the side-wires or one leaf beyond the bunch. The leading rod and crop may be increased annually, at the same rate until the top of the house is reached. During the growing season the roots should never be allowed to get dry, and heavy cropping must be avoided at all times. Insects may be troublesome sometimes in summer, but they are generally not so plentiful in a cool as a hot house. Occasional syringings will keep down red spider and thrips, and mealy bug or any other insect must be cleared off when the Vines are pruned.

J. MUIR.

A Spur-pruned Peach tree.

Spur-pruned Peach Tree.—The accompanying is an accurate representation of a Peach tree spur-pruned by a skilful Continental fruit grower, who adopted this kind of form. In fact, it is such a tree as one might see in M. Chevalier's garden at Montreuil, and as such is useful in calling attention to a system very different from the one we pursue in this country in the case of the Peach tree. The spurs are cut in rather closely every spring, and the whole tree kept perfectly under control. Excellent crops of fruit are borne by trees trained in this manner; it is probable, however, that the fan-trained system common in England is, when the stocks are of the best kind and the training and culture good, on the whole, better than this one. Be this as it may, the perfect control exercised over the tree, the equable furnishing of fruit buds in every part, and the beautiful symmetry of a tree thus managed have an interest for all students of fruit culture.

Selecting Keeping Apples.—It is familiar to most orchardists that some Apples of the same variety in the cellar keep much longer than others. Some of the Baldwins (says the "American Cultivator"), for instance, begin to rot in December, even without having been injured by bruising. Others will remain fresh, solid, and sound until April or May. These different specimens, with all grades between them, are promiscuously mixed together. It is worthy of enquiry whether the long keepers do not come from particular trees, which from soil, culture, age, or other influence, ripen their specimens in such a way as to enable them to resist decay. By keeping the crop from different trees separate, something valuable might be learned in this way. An examination into the causes might possibly enable us to control in some degree the keeping qualities of different sorts.

Renovating Old Apple Trees.—I have just noticed in THE GARDEN (see p. 514, Vol. VIII.), some remarks on this subject. The following account of how I treated some old standard Ribston Pippins—planted by my great grandfather—is at your service. I was urged by some friends to cut down the old trees, which were apparently past bearing. Every year they blossomed freely, but had not strength enough to carry fruit. However, having a vivid recollection of the delicious Apples which they used to yield when I was a boy, I determined to manure them vigorously, and encircled them accordingly, at 12 or 15 ft. from the stem, with manure from the farm-yard near by. I persevered for two or three years till I killed the Grass below them; but, to my delight, I noticed that each year they made longer shoots, and when the new wood thus made became ripe I had sackfuls of beautiful fruit, which, at 30s. a sack, helped to repay me for my trouble. The place to put the manure is just outside the radius of the branches, where the roots are most likely to be able to take it up.—W. H. F.

Old Vines.—Few will be inclined to dispute the soundness of the practice of "W. D. C." regarding the lifting and renovating of Vines, as the comparative loss of crop is small, and the certainty with which they yield their fruit and ripen it, after the plants are re-established, are matters of great importance where means for growing Grapes are limited; and I have often observed that, after the roots have been removed from a cold sub-soil, either underneath the border or at its front, and plenty of new roots have formed near the surface, there was no difficulty in getting the fruit to set freely. It may be observed, that often, in the case of shallow borders formed with extra attention to porosity of soil, that the Vines did well for a few years, and then suffer much from some cause unknown—red spider and shanking; or, it may be, that there was great difficulty in getting the fruit to set and ripen properly. My experience has been, that the very pines frequently taken to ensure success have led to mischief. I need hardly remark that, in very open borders, the roots push their way very rapidly to the extreme limits of the new soil, under which a bed of wet clay may be found by the various feeders: they do not turn back to the good food they have so quickly passed through, but pierce the unkindly soil, where they almost become sealed from the influence of sun and air, and the roots, not being fibry, but like thongs, by the fact of their having received no check in their progress through the open soil, soon fall victims to many evils destructive to plant-life, for which there is no cure except a new addition to the border, or the entire removal of the roots from their unhealthy quarters. Deep open drainage, through which the roots can easily pass to the sub-soil or to the concrete, are evils which do not always receive due consideration when new borders are formed, and if at any time there is an absence of sufficient moisture at the roots, they naturally go downwards in search of what is so essential to their existence. Among many old Vines which I have been successful in renovating was a black Morocco, which was lifted out of cold clay at a place in East Anglia. Though it had borne no fruit but small stonless berries previously, the raising of the feeders to fresh soil gave results of the most satisfactory character.—M. T.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Select Pears (E. S. W.).—1, Jaxonelle; 2, Louise Bonne de Jersey; 3, Thompson's; 4, Henri's Superfin; 5, Benrédé Bosc; 6, Doyenné du Comice; 7, Marie Louise; 8, Glou Morceau; 9, Marchal de la Cour; 10, Benrédé Rance; 11, Pitmanston Duchesse; 12, Winter Nelis.

Purple-leaved Nut.—This should have a place in every garden, its leaves being as dark and effective as those of the purple Beech. It may be kept dwarf by cutting the longest shoots back every winter. It should be planted before the leaves start into growth, and it will thrive in any ordinarily good soil, and in the most exposed situation.—J. Murray.

Gloria Mundi Apple.—This is one of the largest of Apples; we had many last season which weighed over 1lb. each. It does best in the form of espaliers or low bush trees, as the fruit, being so large, is apt to get blown off or bruised on high trees. Its season is from October to January, and it is an excellent culinary Apple.—J. G.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Fuchsias.—Where these were struck early in autumn and kept through the winter in a temperature of about 50° during the night, they will be found to have made the finest plants. When the small pots they were put in after being struck have got moderately filled with roots, they should at once be shifted before they have become stunted, which will most assuredly occur if the roots get matted, the effect of which is fatal to free growth afterwards. They may at this time be transferred to pots 4 in. larger than those they have been kept in through the winter; and the soil ought to consist of four parts of good ordinary loam to one of rotten manure and leaf-mould in equal proportions, to which a good sprinkling of sand should be added, but do not make it too light, as Fuchsias progress most favourably in moderately strong material; for this reason, in potting them ram with the potting lath the new soil, so as to make it quite firm. Keep them for the present in a night temperature similar to that in which they have been during the winter, increasing it during the day as the sun gets more power. Syringe them freely overhead every afternoon; this is necessary to promote growth, and to keep down red spider, to which they are much subject. Stop the shoots so as to keep them bushy, and check a disposition to flower until the plants have attained the size required. Where amateurs have not the convenience of keeping up the temperature necessary for these young plants through the winter, a few of the old plants that flowered during last season, and that were recommended to be pruned back some weeks ago, should now be placed in heat. These old plants will naturally bloom the earliest, and will also furnish cuttings that may be taken off and struck when they have grown to about 2 in. in length. A few young ones should be struck every year to take the place of older plants, which may with advantage be planted later on in the borders out-of-doors. The following is a selection of the best kinds in their respective colours, both old and new:—*Light varieties*—Schiler, Fairest of the Fair, marginata, Annie, alba coccinea, Josephine, Water Nymph, and Star of Light. *Dark varieties*—Wave of Life, Noblesse, Empress of Germany, Inimitable, conspicua, and alpha. *Double white varieties*—Euchantress, Alexandrina, Pursuit, and Mrs. E. Bennett. *Double dark varieties*—Triumphant, Marksman, and Prince Leopold. The light variety, Arabella (syn. with Mrs. Marshall), so much grown for Covent Garden Market, is still one of the very best decorative kinds, flowering very early. The old corallina is yet unsurpassed for clothing a pillar or a wall. Amateurs, who wish to add to their collections of Fuchsias, may select all or any portion of the above, as they produce not only fine individual flowers, but have a free, close habit of growth, forming handsome plants.

Lilies in Pots.—From such that has been written respecting the cultivation of Lilies, amateurs who have hitherto given their collections in pots may be induced to turn them out into the open borders. I should advise discrimination in this, as it is evident many of the more recently introduced kinds will not succeed nearly so well in the open ground in this country as they will in pots, if, when so grown, the treatment be such as they require. The greatest success that has yet been attained, even with any of the Japanese varieties in the open border is a long way behind that which has been reached by the most successful pot culture. I mention this through knowing the failures that have attended indiscriminate planting out, especially in the north of the kingdom. The soaking they are subject to through the heavy autumn rains which we usually get every season appears to be injurious to the roots—falling, as they do, when the tops are dead or dying. Where the potting was done soon after the tops were decayed, as at the time I urged it should be, and the soil has been kept since in a slightly moist condition, all that is requisite now is to keep them where they will be out of the reach of frost, but where the shoots appearing above the soil will get from the first plenty of light. If allowed to remain in sheds, under greenhouse stages, or in similar out-of-the-way places, until they have made even a few inches of growth, they will be so injured that no subsequent treatment during the season can fully rectify; neither must they be put under the influence of a higher temperature than that of an ordinary greenhouse. Where the potting has been delayed until the present time, and the pots are too small to sustain them through the season, they should at once be removed to others that are larger without breaking the ball or disturbing the roots in the least; in fact, the crocks necessarily used for their drainage must not be shifted if the roots of the failures attend themselves in any way to them. Three-fourths of the failures attending Lilies under pot culture are owing to their roots being disturbed when they are growing. Large masses of soil, as the different sorts of *L. lancifolium*, that have not sufficient root-room, and where, nevertheless, it is not deemed desirable to increase the size of pots, should at once have the surface-soil removed, working it

out with a pointed stick down to the tops of the bulbs, at the same time taking away and potting separately all the young bulbs that were formed last summer on the base of the stems; this can be done without touching the roots, for all that are living at this time of year will occupy the lower portion of the ball beneath the bulbs; then fill up the pots to within 1 in. of the top with good loam of a turfy nature, if obtainable, to which add one-fifth of thoroughly rotten manure, such as has been used for hot-beds last season.

Miscellaneous Plants.—Where *Solanum capsicastrum* and *S. pseudo-capsicum* are grown from seed, they should at once be sown in heat; if placed where a night temperature of 50° can be kept up it will be sufficient; the seed should be put in pots or ordinary seed-pans in two-thirds loam to one of sand and leaf-mould sifted, covering them with $\frac{1}{2}$ in. of the finest of the soil; they will soon vegetate; when up place them near the glass or they will get drawn, which will prevent their forming bushy plants. When large enough to handle, pot them singly in small pots, from which they can be either moved into others 6 or 7 in. in diameter, or they may be planted out in a sunny border and grown for the summer and afterwards potted; this latter is the best mode of treating them. Where these most useful winter decorative subjects have to be raised from seeds, no time should be lost in sowing them, or they will be late in forming their berries, and, consequently, will not get their wanted colour before winter. The old *Humea elegans* is not only one of the best plants for relieving the flat surface of the flower garden, but it is a handsome pot plant for the decoration of the greenhouse, the corridor, &c. To have them in good condition, they should not remain too long in the pots they were moved to in the autumn, or the lower leaves are certain to turn yellow and fall off, which completely destroys their appearance; to avoid this, they should at once have more root-room; 10 or 12 in. pots will not be too large, using rich soil and keeping them near the light in a greenhouse temperature, so as not to excite growth, otherwise they will get drawn up weakly. They are very subject to green fly, which, if allowed to get established upon them, will quickly discolour the leaves—a condition which cannot afterwards be rectified.

Vineries.—As I some time since urged, it is not advisable for amateurs who have not had considerable practice with Vines to attempt very early forcing, as with such the chances of failure are increased; but those who happen to have more than one house in which Vines exist will find it most desirable to treat one so as to get the fruit ripe as early in the season as there is a likelihood of success, and to have the second in as late as will permit of their being ripened before the season is too far advanced. With this intention one house should now be started with the night temperature up to 55° at the commencement, giving air in the daytime, and syringing the Vines overhead morning and evening. Such a house will be found very useful for bringing on many other plants. The outside border will be all the better for having 3 or 4 in. of rotten manure spread over it, and on this 8 or 10 in. of stable litter to keep the surface from being frozen. Do not tie the Vines up in their places till the young shoots have shot out an inch or two, or they may not break freely towards the bottom. This is more particularly the case should they be young.

Peaches.—Where Peaches are grown under glass with the aid of fire-heat it will now be advisable to start them, turning on a little heat to raise the temperature up to 50° in the night, giving air in the middle of the day, but closing the lights early in the afternoon; syringe the trees overhead at the same time, but be careful not to have the house at any time too hot. In this it is always well for those who have not had much experience in fruit forcing to err on the right side in not using too much heat, especially at the commencement. See that the soil is sufficiently moist, not merely near the surface, but as low as the roots go; to make sure of this, it is always safe practice to test inside borders at the time the trees are started. This can readily be done by the use of a piece of strong tin or thin iron pipe, something like an ordinary gun-barrel, but open at both ends, and long enough to reach to the bottom of the border; if this be pressed down into the soil it will, of course, when drawn out, come up charged with it; by using a stick that will fit the bore of the pipe the soil can be thrust out almost entire, and its condition as to moisture right down to the bottom will thus easily be seen. By the use of a simple instrument of this kind in different parts of the border there can be no mistake on this most important matter in the cultivation of all kinds of fruits, but especially the Peach, to which a dry condition of the roots is more injurious than others.

Greenhouses.

The Zonal Pelargoniums, both single and double, form a very showy and interesting class of plants. For summer decoration they are most valuable, as they come in to succeed the large-leaved and fancy kinds, and continue in beauty till they have to

make way for the Chrysanthemums and other autumn-blooming plants. A portion of the old plants that have been wintered in pots should now be shaken out and re-potted, preparatory to starting them into growth. Where size is desired, the shoots should be simply stopped, or only slightly shortened back, as there will be no difficulty in getting them to break if the weak shoots be thinned out. A good stiff fibrous loam, without any admixture whatever, is the best soil to grow them in, as they make much firmer short-jointed wood in this way than they do when a more loose open compost is applied. In potting, re-place them in the same-sized pots, or smaller, if the roots can be got fairly into them, as the plants will be benefited by another shift later on. Pot firmly, so that when finished the soil will not yield to the touch; and, when potted, place them in a good light position on shelves, or as near to the glass as possible, and where they can have a little heat to give them a start. The tops, or young shoots removed in thinning them out, may be made into cuttings, and these will form capital plants for successional blooming, or to stand through the following winter to be grown on again in the spring. A few pots of Mignonette sown now are sure to be useful to come in before it can be got ready in the open air, and to succeed such as are now becoming exhausted from winter blooming. The best way to grow this is to drain freely, using small crocks for this purpose. Over this place a handful or two of rough fibrous loam, in which some soft and well-rotted manure has been mixed up. Fill up the pot as firmly as possible with good yellow loam, and water twenty-four hours or so before sowing the seed, leaving the soil that time to settle and drain. Slightly cover the seed, and give no more water till quite dry again, as the plants go off if the soil become at all wet. Cinerarias, to bloom early next autumn, must be sown at once, and any that have their pots well filled with roots, and showing for bloom, should be assisted with manure-water as often as they become dry. Others, intended for late blooming, must be grown freely on by shifting them into larger pots as often as becomes necessary. They should never at any time be allowed to become pot-bound until they have attained the desired size, or are placed in their flowering pots. The soil for these can scarcely be too rich and open, and at least a third of very mild, thoroughly decomposed manure and leaf-soil may be added to the loam. Pot somewhat loosely, that the roots may be able to penetrate the soil in a free manner. Water liberally, never at any time allowing the plants to become dry, or a stunted growth and discoloured under-leaves will be the result; keep the atmosphere as humid as possible, and syringe freely overhead on the afternoons of fine sunny days, closing the lights at the same time. In arranging these in the greenhouse as they come into bloom, keep them as far from the hot-water pipes or other heating surface as can conveniently be done, as dry heated air of this kind is fatal to their beauty. *Lachenalias* will now be showing bloom, and a more useful or desirable plant for decorative purposes at this season it is impossible to have. If the pots have a sufficient number of bulbs without being actually crowded, they will form a fine display. To add to their vigour and assist them in developing fine heads of bloom, the pots may be placed in small shallow pans that they may have the benefit of an abundant supply of water at their roots. Keep them close up to the light that the flower-stems may come straight and strong, so as to stand erect without any support, which would be a great disfigurement to them. There is generally so little variety in the greenhouses during the summer and autumn months, that anything to afford some change from the ever-recurring Balsam, Fuchsia, and Pelargonium is sure to be very acceptable. There are now so many good things among hybrid Begonias, that anyone desirous of adding variety is sure to be charmed with their beauty. Such comparatively hardy kinds as Cheloni, Sedeni, Professor T. Dyer, and a host of others are just at home in the greenhouse, while many similar hybrids succeed well out-of-doors. Seed of these sown at once in gentle heat will make good flowering plants before the season is over, but to make anything of a show, a few bulbs should be purchased and started to grow at once. Another exceedingly useful plant for autumn decoration is the *Celosia pyramidalis*. Its brilliant feathery plumes, ample foliage, and regular symmetrical habit render it an object of great beauty, while its lasting properties and the pleasing effect it produces when cut and used for dressing among other flowers is unapproachable. To get these fine and of large size they should at once be sown in heat, and, when up, be pricked out in light rich soil, and potted on when of sufficient size for that purpose. The berried *Solanums*, so useful for winter decoration, should be looked over to have seed saved from the best varieties. This can scarcely be sown too soon as the plants do not attain much size in one season, and therefore all those of a year old, and the best of others, should be kept over for the purpose of cutting back and planting out when the time arrives for so doing. Keep a few of the best of the Cyclamens and Primulas on shelves

well up to the light, for the purpose of getting them to seed, and mark any of the former that are at all inferior, only saving such as are distinct and good. By raising a few every year and saving only the best, a good stock of really superior kinds may soon be obtained. Seed of these should be got in now in order to get plants of sufficient size for turning out in May or June, as they grow much faster than when confined to the limited space of a pot.

Camellias.

Any Camellias so thinly set with bloom-buds as not to be deserving of room among the general collection of flowering plants should be removed and looked over with a view to starting them into growth. If the plants be healthy and vigorous, they may, with safety, be thinned out where the shoots have become thick and crowded, so as to cross each other and obstruct the light and air from playing freely through the plant. Camellias are very amenable to the knife, and by a judicious annual use of the same they may be kept to almost any shape desired, but with these, as with most other plants, a loose free pyramidal form is by far the most pleasing. If the plants have already attained sufficient size, the leading shoots should be shortened back a few inches, taking care, when doing so, to make the cut at a good prominent bud. To save removing the biennial buds thus late in the season, when it is desired to limit the size of the plants, I have always found it the best practice to remove all the young wood buds from the ends of the shoots the moment they show themselves, or are sufficiently forward to be distinguished from the flower-buds. By so doing, those partially developed, that exist at every leaf lower down the shoots, are induced to break, and then, after blooming, they can always be cut back to any of these. Treated in this way, I have never found the least difficulty in keeping plants well wooded back, and of the same uniform size as long as it was considered desirable. If these terminal buds are allowed to remain till the plants have done blooming, most of them will have pushed into growth more or less, and if pruned back after the energies of the plants have been severely tested in carrying a crop of flowers and starting the terminal wood-buds, they could not be expected to break back with the same strength and vigour they would have done had the sap been concentrated in developing buds at an earlier date. To get Camellias into bloom early, they must be induced to make their growth early, and for this reason I advise the removal from amongst others of such as have only a few blooms on them. By taking advantage of moist heat as early as possible, Camellia blooms may be had just as easily during November and December as they can any time after. To attempt to force them into bloom is only to sacrifice any flower-buds they may have formed, as they are sure to fall off if artificial heat be applied, or if they should happen to remain on, the blooms will be very small and inferior in every way to what they would have been if allowed to come on in the ordinary greenhouse temperature. There are some varieties naturally much earlier than others—as, for instance, the old Double White, Chandleri, Donkelari, imbricata, Jubilee, and many others, so that by getting any of these into heat as early as possible when they have done blooming, or do not show a sufficiency of flower-buds for keeping them on, Camellia blooms may be had during the whole of the winter, where there is a sufficient stock of plants to admit of them being treated as above. With plenty of moisture in the atmosphere and liberal syringings overhead, the Camellia, while making its growth, will stand almost any amount of heat, and may therefore be placed in any forcing-house, or any other structure where it can have a little shade while pushing into growth. Much difference of opinion exists as to the proper time of potting these, but as all evergreens are in an active state at the root during the time they are making their young growth, there can, I think, be no doubt that the above operation should precede that period so as to enable the plants to get well hold of the soil, and having something fresh to grow in during the summer while ripening their wood and forming fresh flower-buds. If deferred till this has taken place, roots are then becoming inactive, and the fresh soil remains in the pots or tubs unused, in which state it is apt to become wet and sour during the winter, and consequently totally unfit for the purpose intended. Therefore, any plants that require re-potting or tubbing should have that attention as they go out of bloom; and, if possible, before the young wood-buds have pushed into growth, as, when they have done so, there is much danger of injuring the young tender leaves, which, if scratched or bruised in the least, would be permanently disfigured. Before re-potting, remove as much of the old inert ball as can be done with safety without injuring the young roots, which in Camellias are very brittle. The best soil for them is the old regulation mixture of peat and loam, which should be used in the proportion of about one-third of the former to two-thirds of the latter. Both of these should be of a tough fibry nature, that have been stacked up for a time; and, in chopping them up for use, keep both

moderately rough, so that the roots may be enabled to penetrate it freely, and the water to pass readily through. When used coarse, with plenty of large fibry lumps, the air, as well as moisture, permeates the whole freely, and keeps it in a healthy, wholesome state for the roots to feed on. Where it may be desirable to limit any to the sized pots or tubs already occupied by them, they may with benefit receive a liberal top-dressing of a somewhat richer material than that advised for re-potting them in. To effect this, remove as much of the top of the old ball as can be got away without destroying any roots, and replace the same with good fibry loam, to which add some sheep or cow manure that has been seasoned by laying up for a year or so. Give plenty of manure-water to such as are pot-bound or are carrying a heavy crop of bloom, whenever they require moisture at the roots. See that it is perfectly clear and not over-strong, as it is much better to give it weak and often than in strong doses at longer intervals. Nothing is better for the purpose or more easily made or obtained than clear soot water, to which a tablespoonful of guano may be added. The fertilising effects of these soon show themselves, and they have the advantage over most other liquid manures in that they may be used without being offensive. Where cut blooms of Camellias are in much request, and a convenient place can be found for planting a few strong plants out, large numbers of flowers may be obtained, and finer in every way than from such as are grown in pots. Such shade-loving plants as Camellias will do well in almost any position under chimneys, or on the back walls of greenhouses, vineries, &c., where little else would grow. In the latter positions we keep our most useful plants for the purpose of supplying cut flowers, as they are always in at least two months before we can get a bloom elsewhere. Being at the back of the first and second vineries, they have got into the habit of making their growth early, and, with that accomplished, the blooming stage is advanced with the same certainty. The Camellia, unlike most other flowering plants, appears to require a certain time from making its young wood till it expands its flowers; and if the growth be late, no coaxing in any way will induce it to bloom early, as it soon resents the application of artificial heat by shedding its buds. Once get it into the habit of starting early into growth and there will be no difficulty in keeping it up afterwards.—J. SHEPPARD, *Woodrostone Park.*

Indoor Fruit Department.

Vines.—Muscats to be ripe in September, with a high finish and good keeping qualities, should now be started, after having been properly cleaned, and the roots and borders put in good order by removing sufficient surface-soil to enable a top-dressing of the richest compost to be given. The latter should chiefly consist of good cow-manure, so placed that the roots can ramify in it early in the season; cover it over with fresh loam so as to present a neat appearance, and give the whole a thorough soaking with tepid water. Keep the house close, and syringe the Vines and all available surfaces night and morning. Before starting the Vines should have been pruned for some time, and the wounds hard and dry, if not, apply Thomson's Styptic to prevent bleeding. Where the first fruit is to be gathered from pot Vines and where the bunches have been thinned, push them briskly along by day and keep the night-temperature at about 60°, rather under than over; that when the weather is favourable give front air at dusk, and water with tepid manure-water when required. Discontinue syringing where the foliage is expanded, but carefully damp all canes or any portions of them on which the buds have refused to break. Where Vines are in flower and require fertilising, we use a fox's tail for the purpose, which we find not only speedy but effectual. Vine-eyes, got ready as before recommended, should be started in a temperature of 55°. All pruning hitherto deferred should be done at once, and the wounds dressed with Styptic.—J. HUNTER, *Lambton Castle.*

Peaches and Nectarines.—It is not a very general practice to thin out the flower-buds of these when borne thickly on the trees, but when the practice is performed judiciously it is an operation of great importance in the successful culture of Peaches and Nectarines, whether for early or late supplies. It is well known that those buds which are best placed, and of the most compact form, are by far the most likely to set freely and yield the finest fruit; and those which set large and are well formed take the lead and hold their own to the last. These statements are strongly supported by a Peach-grower whom I visited a few days ago, and whose success with both late and early cordon-grown fruit is not surpassed by any cultivator with whom I am acquainted. His Peach trees, for early fruiting (about the end of April), are kept very thin in the bearing wood; and the buds, which are expected to set best, are left. There is no "dropping" of flowers, and it is seldom that any small useless fruits are formed. Allow the fruit-buds to stand thin enough, so that they can fully expand, and have the full influence of

THE ART OF FORESTRY.

THE area over which the experience of the skilled forester extends is very wide, whether regarded according to its geographical range, or according to its physiological extent. From the high-water line of our tidal seas—from the lower level at which the scrub of the Ghor is washed by the rapid torrent of the Jordan, 1200 feet below the surface-level of the Mediterranean—to the lower line of perpetual snow on lofty mountain ranges, each orographic province, or zone of vertical ascent, has its appropriate Flora. The forester must be acquainted, not with timber trees alone, but with at least as much of the organic world as is connected, whether in a friendly or in a hostile mode, with their growth and welfare. As to actual trees, the range in size extends from the minute form of the Alpine Willow, which we have picked on the summit of Skiddaw, of less than 3 in. in height, to the lofty column of the majestic Wellingtonia, which towers in the Yosemite Valley, to an altitude of 350 ft. A height of 200 feet is attained by the Umbrella Pines of Italy. In Slavonia the Sapin (*Abies pectinata*) attains an ordinary height of 275 ft. The *Eucalyptus amygdalina* is described by Dr. Mueller as attaining on the banks of the Yarra River, in Victoria, the height of 420 ft. in many instances. The Californian big tree is said to measure 96 ft. in girth. In length of life and rapidity of growth the diversity is no less marked. A *Pinus sylvestris*, from Finland, 70 ft. in height and 72 in. in girth, has been found to register the passage of 618 seasons by its concentric rings. The venerable Yews that form a majestic avenue at Studley Royal, or the yet more magnificent patriarchs of the same species that form a kind of Druidic circle in the sequestered and beautiful glade near Guildford, known by the name of "Fairy Land," must have been in existence when the wood of the Yew decided the fate of battle in Norman or even in Saxon times. The *Eucalyptus globulus*, on the contrary, rapidly attains gigantic dimensions. It has the property of absorbing ten times its weight of water from the soil, and of emitting antiseptic camphorous effluvia. When sown in marshy ground it will dry it up in a very short time, according to the evidence collected by M. Gimbert, mentioned in the "Medical Times and Gazette." In the spring of 1867 about 13,000 of the *Eucalyptus* were planted at Pardock, 20 miles from Algiers, in a plain situated on the banks of the Hamyze, and noted for its extremely pestilential air. In July of the same year, being the time when the fever season sets in, not a single case occurred; the trees were by that time 9 ft. high. Notwithstanding this rapidity of growth the wood is of great strength and tonacity; and is to be obtained in any lengths. The *Eucalyptus rostrata*, or Red Gum, again, is a hard dense wood, almost indestructible in water or in damp ground. The wood of some amentaceous trees, and even of the Conifere, is converted into pulp for the manufacture of paper; and a Japanese tree furnishes a pulp for this purpose, which more resembles gelatine than ligneous matter in the ease with which it can be manipulated.

The general problem of the distribution of trees and other plants over the surface of the earth was not only unsolved, but unstated, before the time of Linnaeus. Even now we are apt to forget, in mentioning that illustrious man, the mode in which, in his "Philosophia Botanica," he indicated the course which has since his time been followed by the most eminent Continental botanists, more especially by the De Candolles, both father and son. The first principle of distributive, or geographical, botany is, as in the animal kingdom, that of the development of species in proportion to the dose of heat. In vegetables this dose is derived from the sun alone. It is thus a question of habitat. The more directly the rays of the sun strike the surface of the earth, and the more dense the atmosphere which they penetrate, the greater is the amount of sensible heat and light. In moving from the equator to the pole we experience a diminution in the sensible influence of the sun's rays which very closely resembles that which is felt in ascending a lofty mountain. Thus while the Equatorial Flora is limited to a narrow belt of earth, the Arctic or the Alpine Floras, the plants of low latitudes and those of great altitudes, are akin, or even identical. Eight successive zones have been pointed out, each of which may be roughly described as determined by an isothermal line dependent on the combined influence of latitude and altitude. In regarding both the Northern and Southern Hemispheres; the number of zones will be increased to fifteen; although, from the unequal distribution of land and water, the area for vegetation is far less, and the isothermal lines are nearer to the equatorial level in the southern than in the northern part of the globe. These fifteen zones have been divided by Professor Schouw into twenty-five botanical regions, each of which is defined, not by geodesic or photometric considerations, but by the observed prevalence of certain known families of plants.

In the Polar zone vegetation is confined to the Alpine plants, which rise but little above the level of the soil. Mosses and Lichens reach to the snow-line. The Arctic, or Sub-polar zone is the zone of

Rhododendrons, which Dr. Hooker has found in the Himalayas at from 7000 to 10,000 ft. The *Befarias*, which in the New World represent the Rhododendrons of the Old, rise to the height of 13,420 feet on the Andes of Quito, or 120 ft. above the mean limit of shrubs. 11,400 ft. will be the mean limit of the region of Pines, which succeeds that of Rhododendrons. This elevation is attained by the Oak (*Quercus semicarpifolia*), on the south side of the Himalaya Mountains; while on the north the Birch (*Betula alba*) grows as high as 14,600 ft. On the Pyrenees the *Pinus uncinata* is found at 10,870 ft. On the Andes of Quito the *Escalonia* occurs at 11,500 ft. above the sea. The Sub-arctic zone of the Pines is succeeded by the cold temperature zone of the European trees. The warm Temperate zone, that of the evergreen trees, follows; then the Sub-tropical zone, of Myrtles and Laurels; the Tropical zone, marked by tree Ferns and Figs; and, finally, the Equatorial zone, which is the region of Palms and Bananas.

The distribution in longitude of the various local Floras must be regarded as an observed fact alone, as to the original cause of which science has as yet been unable to afford any indication. Why the *Asters* and *Solidagos* in North America should occupy the region filled, in a zone of equal temperature in the Old World, by the *Labiato* and *Caryophyllaceae*, while the same temperature of from 52° to 72° in Australia and Tasmania calls to life the *Egnorides* and *Eucalypti*, we have yet to learn. The law of the localisation of distinct families of plants is one of the most important objects to be ascertained, not only by the student of forestry, but by the physiological botanist.

The economic value of the products of forestry is of the very first importance. Even considered as a matter of import and export, under which aspects it is possible to arrive at a comparative estimate of the actual commercial movements caused by this great industry, of this importance will be manifest. But the absolute necessity of this importance will be manifest. But the absolute necessity of this importance is, far more vital to our civilisation than it is possible in any way to indicate by the tonnage and money value of the imports. No adequate substitute can be found for wood. For one purpose, indeed, that is, for fuel, the mineral relics of contemporaneous vegetation. Nor is it probable that in the lifetime of the existing generation there will be much change in this respect. But it must be borne in mind that however great be the supply of coal in any country, or in the whole coal-measure of the earth, it is a limited and definite quantity. It is a provision which, if constantly sought, must come to an end sooner or later. It has no reproductive power. To an ordinary appreciation it may matter little, so that we are unlikely to witness either the exhaustion, or the panic of exhaustion, of our own coal-fields in our own time, by how many centuries of consumption we may gauge the coal supply of the world. Such will not be the case with the statesman or with the philosopher. To the man who loves his country, who seeks to serve her, and who desires to leave to history the name of statesman or patriot, it must be already evident that the optimist and pessimist views of the durability of our home coal supply are alike extravagant. Whether we accept the highly imaginative estimate (if it can be called by that business-like title) of the Commission of 1871, of a possible supply of 90,000,000,000 (ninety thousand million) tons, reaching down below the surface of our island to a depth where the temperature exceeds 122° Fahr.; or whether we take that practical correction which, by excluding coal that, if it exists, would be impracticable to win, reduces that quantity to a little more than a third, little matters to our present argument. In the latter case our coal-fields would be exhausted, allowing consumption to increase as it has hitherto done, by the year 1915. In the former case the term has not been suggested. But a century sooner or later in the history of a great nation is a matter of comparatively little importance, when it is a question of the displacement of the very centre of gravity of its industrial condition. Again, it is true that the coal-fields of the United Kingdom amount to only some four per cent. of the coal-fields of the world. But this disproportion is not greater than that which exists between the population of the United Kingdom and the population of the world. And even if we strike off the enormous number of the non-industrial, non-coal-burning part of the human race, we still are forced to the conclusion that a result which may be due in one or two centuries in England, and which may be possible in three or four times that length of time in the whole world, is not one which the statesman can afford to ignore. At a period of time not greater than that for which Westminster Abbey has stood (dating, not from the Conqueror, but from its rebuilding under Henry III.), it is probable that the coal supply of the world will have been rified of its cream. If by that time the forests of the world be also destroyed, the future will have a gloomy outlook. Those forests, wisely managed, are adequate to keep the human race in fuel; but if destroyed at the rate at which

destruction is going on in some localities, it will be as impossible to restore them as to win back the coal that has been consumed.

At the present time our annual imports of timber, cork, bark, and dyewoods reach the value of some fourteen millions sterling. Of olive, palm, and cocoa-nut oil we import to a value exceeding three millions sterling. Of turpentine, tar, resin, pitch, india-rubber, gutta-percha, and other gums, we import again something in excess of three millions sterling. This total of twenty millions sterling represents a certain regular demand for definite forest produce. If we regard those requisites of daily life which form the subjects of special industries, closely allied to that of the forester, regulated by the same principles, and requiring for their most successful pursuit the same advanced kind of education, we pass from tens to hundreds of millions. In wine and similar products we import to an amount of nearly twenty millions sterling per annum. Our imported corn, grain, flour, rice, and pulse amount to forty-four millions. Sugar, fruit, spices, and condiments; tea, coffee, and cocoa; tobacco and hops; indigo, madder, and other dyes; cotton, jute, hemp, and flax; Esparto Grass for paper-making; vegetable oils, not from the Olive or the Palm; opium and other drugs, flowers, culinary vegetables, and garden seeds, make up a gross annual total exceeding £125,000,000; and a grand total of vegetable imports (exclusive of materials partly of vegetable origin, such as wax) of £210,000,000. This is close upon two-thirds of the total value of the imports into the United Kingdom, which may be roughly taken at the rate of £1,000,000 per diem, counting working days alone. The year from which we have taken our figures is the year 1871, in which the total value of imports is set down, in the House of Commons Returns, at £326,834,647. It has the further convenience of being a census year. The total imports of 1871 were in excess of those of 1870 by £23,577,154, and the latter exceeded those of 1869 by £7,797,279. The amount of vegetable produce annually imported into England is more than double that which the agriculture of the country is as yet able to rear. The land under grain, Grass, and green crops in England and Wales, is about 25,000,000 acres. The number of persons occupied in agricultural pursuits is one-fourteenth part of the population. The return has been estimated at an average of £4 an acre. But this includes the value of animal produce, which is not included in the imports quoted. It is true that very much more might be produced in England and Wales, by the direction of labour now wasted, to the reclamation of uncultivated soil, and especially by the scientific drainage and irrigation of our river-valleys. But it is not a question of area alone with which we have to deal, it is also one of climate. It will be apparent from the summary above given, that a large proportion of our vegetable imports consists of products which Nature has denied to our soil. The tea and the coffee, the spices and condiments, much of the fruit; the quinine and the opium; the cotton, the sugar, and the rice; the indigo and other dyes; the oils, the resins and the gums, that form so large a portion of our imports, could not be produced in our climate. Tobacco is, perhaps, the only important item of this class, the home growth of which is prohibited, not by Nature, but by legislation. But if not from the British Isles, yet from the territory of the British Empire, all these, and far wider demands can be amply supplied. Of our imported corn and breadstuffs, only about one-tenth part comes from our colonies; fully a third being supplied by the United States, and another third by Russia. From Russia, too, comes more than half of our imported hemp and flax. But hemp is now supplied us from India; flax from Australia; and the special products supplied by almost any foreign country may be obtained, by proper culture, from our own colonial territories. Of some we have, if not the monopoly, yet certainly the most available and productive sources, or, at least, the districts which might be converted into such sources. If we regard the Table of our imports as a sort of bill of fare for the civilised world, the British Empire is able to supply that fare from her own resources, not only to her own citizens, but to the markets of the world. In some instances, articles which long were thought to be the special pride of our own country are now very far thrown into the shade by the products of our colonies. Thus the fame of English Oak, especially for ship-building purposes (although somewhat eclipsed, for a time, by the use of iron) is traditional and well deserved. But Oak, although still ranked in the first class at Lloyd's for ship-building purposes, is inferior to well-known timbers produced by our dependencies; timbers which are only the representatives of hundreds of distinct species. The Teak (*Tectona grandis*), and the Saul (*Shorea robusta*) of the East Indies; the Mora (*Mora excelsa*), and the Green Heart (*Nectandra Rodiei*) of British Guiana; and the Iron Bark, to which may be added many other species of Eucalyptus, from Australia, are all stronger timber than Oak, in resistance both to breaking and to crushing weight. The Science and Art Department published, in 1867, a set of Tables giving the results of a series of experiments on the strength of British colonial

and other woods, made by the late Captain Fowke, R.E., on upwards of 3000 specimens of 600 different kinds of timber. The engineering and commercial value of this result of the patient application of scientific method is of the highest rank. The Iron Bark gives a breaking weight of 11,158 lbs. and a crushing weight of 15,349 lbs. against a breaking weight of 4256, and a crushing weight of 4280 lbs. for Oak; the pieces of wood experimented on in each instance being 2 in. square and 16 in. long. The specific gravity of the Iron Bark is 1.204, in specimens both from Queensland and the New South Wales. That of the Iron Wood of Jamaica is 1.254. At the other extremity of the scale, the Dedoaf Tea, from East India, has a specific gravity of 0.260, being only 0.110 more than of Cork. This enormous range in solidity is not more remarkable than the wonderful variety in texture, colour, marking, scent, and other qualities, of the costly and precious woods which fill the virgin forests of our as yet undestroyed colonial territories. It may be naturally thought that the possession of a vast natural wealth of this nature has been wisely appreciated by our statesmen and legislators. Considering the incalculable amount of national advantage, or loss, that must result from the skilful or unskilful management of our vast forest property, and, indeed, from the whole of our colonial arboriculture and agriculture, our readers may expect to hear that the due education of a class of men fitted to be the guardians of such imperial treasures has been carefully provided for by our Government. So long ago as the time of Queen Elizabeth, the student of English literature is aware, the importance of a study of vegetable culture was insisted on by a great writer, who laboured, as few since have done, for the advancement of knowledge. "God Almighty," said Bacon, "first planted a 'garden.'" On the key-note thus struck depends the tone of the entire treatment of the subject by the restorer of modern science. The imaginative beauty of Bacon's views is not more striking than that clear insight of genius which has pointed out the value of thorough study of natural history as the very backbone of a liberal education. No parent or preceptor, who has taken Bacon's advice in this respect has ever, we will venture to assert, found cause to regret having done so. How far has this advice been followed with reference to our public service? Forestry, which holds on the Continent an honourable and even a distinguished place amongst the branches of a liberal education, is, in this country, according to the authority of Dr. Hooker, "a subject so utterly neglected that we are forced to send all candidates for forest appointments in India, to France or Germany for instruction, both in theory and in practice."

Destruction of Woodlands.

In South Africa, according to reports, millions of acres have been made desert annually, through the destruction of the indigenous forests; in Demerara the useful timber trees have all been removed from accessible regions, and no care or thought given to planting others; from Trinidad we have the same story; in New Zealand there is not now a good Kauri Pine to be found near the coast; and I believe that the annals of almost every English colony would repeat the tale of willful wanton waste and improvidence." In the year 1830, out of a total area of sixty-six millions of acres, contained in New Zealand (being about six-sevenths of the area of the United Kingdom), twenty millions, in round numbers, were under forest. In 1868, the forest area had sunk to fifteen millions of acres; in 1873 to twelve millions. Stated as per-centage, the 30 per cent. of forest existing in 1830 had sunk to 28 per cent. in 1868, and to 19 per cent. in 1873. The first thirty-eight years had witnessed the diminution of woodland to the amount of one-fourth, but the second period, of only five years, had seen a further destruction to the amount of one-fifth of the remainder; or at the rate of 4 per cent. per annum. At this rate, the entire woodland of New Zealand would be destroyed by the year 1893. Dr. Hooker wrote the remarks which we have quoted in 1867. At the very time when we reproduce them, the daily press echoes complaints of the wasteful destruction of timber in any corner of the British Dominion, the subject of forestry is receiving adequate attention. It is from that colony in which more thoroughly than in any other part of the world, the English race has struck vigorous root—that island which, from its congenial climate, promises to become the Great Britain of the Antipodes—that the first vigorous protest (with the exceptions above referred to), against wanton forest arson has been raised. We have before us a volume of papers relating to State Forests, their conservation, planting, and management, presented to both Houses of the General Assembly, in New Zealand, by command of His Excellency the Governor, together with a report of the very able speech of the Hon. J. Vogel, delivered in the House of Representatives on July 14, 1874, on moving the second reading of the New Zealand Forest Bill. We cannot do better than avail ourselves of the careful research by which Mr. Vogel has brought together so much

definite and pertinent information on the important questions of the rapid exhaustion of ancient forests, and of the pernicious effects thus produced on climate and on vegetation. But while, as a literary *proctus*, the speech in question has a singular value, the imagination is more impressed by the vivid picture of the actual state of the newly-settled parts of the globe, than even by the statistic calculations. We seem to hear the axe ringing through the wilds; to watch the progress of the flames as they crackle through hundreds of miles of forest. We become aware that, as we write, irreparable destruction is in full career. We see how slow, feeble, and ineffective is the progress of the planter; how rapid that of the desolator; how clear the duty of preserving that which centuries cannot replace.

Forest Management on the Continent.

The aim of scientific forestry, in its present most advanced state, is to convert the irregular growth of a woodland district into what is called a "geschlossener Bestand," or compact forest; divided into distinct blocks of trees of equal age. The usual "Umtrieb," or rotation, for Beech "Hochwald," or high forest, in Hanover, which may be taken as the model State, is 120 years. The forest is so divided that there shall be as nearly as possible six equal areas allotted to as many periods of twenty years' growth. Thus one block will be full of trees not exceeding twenty years old; a second of trees from twenty to forty years old, and so on. When a block arrives at the last period, felling commences by a "Vorberaitung," or preliminary clearing, which is little more than the ordinary thinning carried on from time to time in former periods. The Beech in these woods only ripens its seed every third or fourth year. After the first seed year in the final period, a "Lichtschlag," or clearing for light, takes place, in order to afford light for the germination of young seedlings; the finest trees being left standing. When the ground is well covered with seedlings, the old trees are felled and carefully removed, and the block recommences growth. The tendency to a gradual removal of the old trees appears to be on the increase, so as to make the culture approach as nearly as possible to the natural growth of a wild forest. The staff for the administration of forests in Hanover consists of two branches, which may be described as preparatory and administrative. All preliminary arrangements, on taking a piece of forest land into culture by the State, are conducted by the "Einrichtungsbureau," or survey office. This consists of a "Vorstand," or superintendent; draughtsmen, and clerks who are generally practical foresters; and a staff of surveyors and valuers, who are generally candidates for the office of "Oberforster," the third grade in the system of permanent administration. The surveyor surveys the whole tract of forest, and delineates, with the aid of the valuator, the blocks or sub-divisions into which it is to be divided for permanent culture. A detailed plan is drawn up for the future management, pointing out the mode in which the successive periods are to be worked off, the roads which it will become necessary to make for transport, and the usual details of the condition of the forest. This plan, together with a complete code of rules, is handed over for the guidance of the permanent forest officers. The permanent administration consists of one "Forstdirektor," and "Oberforstmeister," who is also a councillor; twenty "Forstmeisters" in charge of circles or divisions, who form also a consultative council; 112 "Oberforsters" in charge of districts of about 17,000 acres each; 403 foresters; and 343 overseers and under-foresters, who watch the forests, and supervise the work executed by contract or by day labour. A cashier is attached to each over-forester, who receives and disburses all money in and from the forest cash chest, on the orders of the over-forester. A perfect financial check is thus maintained, under the control of the forest-master. The duties of these officials are confined to superintendence. The "Oberforsters" spend the greater part of their time in the forest, supervising the actual operations. So regular and efficient is the entire system that the state of each block of the forest is generally found to be in accordance with the programme laid down on the original working map. There is a forest academy at Münden, and another at Neustadt-Eberswalde, near Berlin. A special branch of the Revenue department of Prussia, presided over by an "Oberland-forstmeister" and "Ministerial Direktor," with suitable branch establishments, exists; and the "Oberland-forstmeister" is curator or governor of the academies. There is also a special office of control, for forest accounts at Potsdam. Captain Campbell Walker, to whom we shall have occasion further to refer, speaks with admiration of the extent and variety of the studies required from forest probationers in Prussia, and the number of years which they spend part in study, and then waiting for appointments. A candidate must keep certain terms at a government school of the first class; then spend a year with an "Oberforster," then pass an examination as forest-pupil. A two years' course of study at

a forest academy succeeds, closed by an examination in scientific forestry, land-surveying, &c.; on passing which the pupil becomes a "forst-kandidat." In this capacity he passes two years more in study, during nine months of which he must do actual duty as a forester. Then comes the final government examination, directed to ascertain the capacity of the pupil for applying theoretical knowledge, as to the acquisition of which he was previously examined. On passing this, the aspirant for employment is ranked as an "ober-forster kandidat," in which capacity he is employed as an assistant in the academies and control offices, in making surveys and plans, or in charge of a "revier" or district, receiving daily or weekly allowances. After five or six years of this probation he may expect a permanent appointment. He will then have spent five years in study, and five more in probation, on very meagre allowance; and is rarely promoted to higher grades than that of "ober-forster," unless he has undergone a two years' curriculum at a university. Such is the degree of care which the Prussians consider requisite for the education of their forest officers. It is no easy matter to form a clear and accurate idea of the forest wealth of the world. Data are wanting in many places, and the information which is accessible has been compiled with so little reference to any but special utility, that the very points which are of most general interest are often omitted, as if of set purpose, from returns. Again, it is often not so much from the want of arithmetical data as from the difficulty with which the mind realises the value of enormous numbers, that our want of general grasp arises. Writers are too apt to pursue inquiries into a degree of detail that is altogether unprofitable, from a philosophic point of view, owing to the doubt that hangs over other portions of a subject of which they only examine particular branches. It must be, therefore, by the widest collection, and most simple grouping, of facts, and by a comparative, rather than by a positive, statement of results, that we can most intelligently seek to present this great field to the imagination.

Extent of Land Under Trees.

The forests of Europe have been estimated by Dr. Brown as covering 500,000,000 acres, or nearly 20 per cent. of the surface of the Continent. In British North America, the average given by the same authority amounts to 900,000,000 acres; in the United States to 560,000,000 acres; in South America to 700,000,000 acres. The total thus estimated, for Europe and America alone, is equal to 3,600,000 geographical miles, containing 736 English acres each. If we regard these forests as productive of fuel alone (as, sooner or later, it is to actual forest growth that mankind will have to look for a permanent supply of fuel), it is instructive to compare the area and products of the woods with those of the coal-fields of the world. The total area of known coal measures is estimated by M. Simonin at 25,000 square French leagues. Four-fifths of this area lie within British and American territory, in North America; one-twenty-fifth is in the United Kingdom. It follows that the estimated area of the European and American forests is nearly twenty-seven times as large as that of the ascertained coal measures of the world. The English coal measures, which are in full work, cover somewhat more than 5000 geographical miles. The coal raised in 1869 was 108,000,000 tons, of which about 10 per cent. was exported. Something more than 20,000 tons of coal is thus annually won from a geographical mile of coal measure in full operation. The yield of our coal-fields, during the periods as to which no exact returns are in existence, rose from 10,000,000 tons per annum, at the beginning of the century, to ten times that amount in sixty-eight years. If the same ratio of increase be maintained, our known supplies, down to the depth of 2700 ft. (at which level the temperature is that of blood-heat, and labour ceases to be available), will be exhausted in the year 1945. This will give us the approximate period of a century and a half for the life of a given coal-field of large dimensions. The actual yield of those forests, which are now in course of systematic culture and working in Europe, varies to a great extent. In the most unfavourable districts of Prussia it is as low as half a load of timber per acre, per annum. In Baden it is four times that amount. The latter ratio is calculated on areas actually under crop; the former includes large districts of waste and moor. As we advance towards the equator, the forest products become more important as regards the size of the trees, the rapidity with which they grow, and the density or specific gravity of the timber. A specimen of *Pinus sylvestris*, from Finland, sent to the Vienna Exhibition of 1867, grown in 60° 50' north latitude, measured no more than 70 ft. in height, and 72 in. in girth, when 518 years old. In the Teak forests of British Burmah it is calculated by Dr. Brandis that the stock may be entirely replenished, under proper management, in 120 years. First-class trees often attain 15 ft. in girth. A poisonous *Antiaris* is described as 38 ft. in girth, and 250 ft. high. The Teak is said to attain

a height of 32 ft. in two years. Thus, if we take the rate of annual production of wood actually attained in Baden (which is less than the weight of hay that can be grown on an equal acre, under favourable circumstances, in England,) as an average of forest production, we shall be very far within the mark. From three to four loads and upwards per acre per annum would probably be nearer the truth than two loads. Limiting our estimate, however, to the lesser figure, we have an approximate yield of 1500 loads of timber per geographical mile of forest per annum. We have seen that a yield of 20,000 tons of coal per geographical mile is now attained in our own coal-fields. It is unnecessary to go into the exact arithmetical mean of a yield which has increased 75 per cent. in fourteen years; the actual rate is ample for the purpose of comparison. Subject to such correction as may be due to the different quantity of carbon contained in a load of wood and in a ton of coal, which depends on the character of the wood, the product of the coal-field is seven times as much, per mile, as that of the forest. To produce a yield of fuel equal to that obtainable from the known coal measures of the world, if worked with an activity equal to that of our own, seven times the area of cultivated forest is required. But the actual area, as estimated, is not seven, but twenty-seven times that of the coal measures. It is thus four times as important, regarded as a source of fuel. But, while the life of the coal-field has been taken at 150 years, that of the forest, if rightly cared for, will endure as long as that of the human family. A wealth such as this is not to be measured in tons of gold. Immense as it is, if considered only as a source of fuel, its value is far higher if we consider the nature of some of these arboral products which form nearly one-seventh part of the total value of our imports. The products of tropical forestry and arboriculture are among those objects which give luxury its chief resources, and life some of its most cherished enjoyments. To restrict our consumption to the vegetable products of our own shores, or even of Europe, would be to return to barbarism. We have, however, only estimated a portion of the existing forest wealth of the world. The proportion of the woodland to the whole area of Europe is estimated at 20 per cent. In America the ratio is 21 per cent.; in the United States alone the estimate of Dr. Brown was 25 per cent.; but by 1870 the proportion had fallen to 15 per cent. In New Zealand we have seen that the 30 per cent. of 1830 had shrunk to 18 per cent. by 1873. If we suppose that the forests of Asia, Africa, and Australasia bear the same common proportion of 20 per cent. to the area of the land, we have a further spread of forest, raising the grand total of the forests of the world to 7,734,000 geographical miles, or nearly fifty-eight times the area of the known coal measures of the world. While a great range of this extent, if duly cared for, and wrought with an eye to the future, no less than to the present, would thus be ample to supply every need of a far larger industrial population than we can readily contemplate as living in those parts of the world where skilled labour finds its natural home, no assumption can be more erroneous, more foolish, or more mischievous, than that the supply, however vast, is inexhaustible. The very contrary is the case. The rate of exhaustion of forest, where we are able to measure it, has been so rapid and so constantly increasing as to cause the gravest anxiety. It must be remembered that we are living at the commencement of the most stupendous revolution that the world has ever witnessed. It is not a political but an industrial movement of which we speak, and an industrial movement attended by unexampled physical results. By the use of machinery moved by heat, and, as the most convenient mode of managing heat yet discovered, driven by steam, we have shifted the centre of gravity of human labour. We are multiplying our new servants, the drudging goblins of the steam engine, at an enormous and ever-increasing rate. The discharge of all the heavier kinds of labour in all civilised countries will soon be effected, we cannot doubt, by mechanical power. With the freedom thus given to the hand of the skilled mechanic, his inventive power is allowed fuller play. Each new process, each improved manufacture, stimulates the energy of consumption. The rate of our own production of coal, which has increased, between 1800 and 1869, from 10,000,000 to 108,000,000 tons per annum, is the best gauge that we can present for measuring the rate of the increase annually taking place in the industrial activity of the world.

Forest Re-production.

It is not easy, it is not always possible, to renew extinct forests. Under some circumstances planting can be resorted to with success; but the general outcome of forest experience is to the effect that the systematic care of self-sown seedlings, and the thinning of the young growth year by year according to definite plans, constitute the true method of providing for forest reproduction. Thus, "In 1839, Mr. Williams, dockyard manager, reported to the Bombay Government that in twenty-one months 40,000 Teak trees, between 12 in.

and 6 in. in diameter, had been floated down by the contractors (in the Travancore Forests) who had been allowed to act indiscriminately, and that the supply of large timber for ship-building was scanty. The prospects of reproduction of the Teak trees had become so bad through this neglect, that Government was advised to purchase 200 square miles of forest land for replanting young Teak for the use of the Government dockyards. This was actually done in 1842. Several plantations were attempted, but it was found that the expense of planting an acre with Teak was greater than the value of the timber likely to be produced, after 100 years, on a square mile! The British provinces of Malabar, Canara, and Gojerat, Bombay, Madras, Rajamundry, Coimbatour, and Cochin, containing Teak forests of vast extent, stocked with first-class trees fit to cut, and a natural growth of young trees reproducing themselves, and capable, with proper management, of yielding an ample supply without any chance of deterioration, had in these thirty years been given over to destruction." Again we find that in 1842, when the Government were made aware of the destruction which they had allowed to take place in Burmah, plantations of Teak were formed in Attaran to remedy this evil. The Teak was found to grow freely from seed; but so little care was taken of the seedlings that in 1845 only one tree was found alive. "Dr. Brandis calculates that in order to make Teak plantations profitable after sixty-two years, the total outlay per acre should not exceed sixty-seven rupees. The actual outlay was, however, over 600 rupees per acre, so that Government planting, as a method of restoring the exhausted forests, is a failure." We should remember that the great demand which must hereafter come upon the forest reserves of the world for fuel is as yet comparatively unmet. In the United States, indeed, the 60,000 miles of railway now in use, or soon to be completed, make a steady annual demand for combustion, as well as for construction. To give 2500 sleepers to the mile these roads require 150,000,000 trees, each tree making generally but one sleeper. These sleepers require renewal every five years; making a demand for 30,000,000 trees per annum. The estimated distance run each day by trains on all the roads is 308,000 miles. Each engine, with an ordinary train, consumes about $1\frac{1}{2}$ cord for every twenty-five miles. This gives an annual consumption of 6 $\frac{1}{2}$ million cords of wood. The 60,000 miles of railway require, at the rate of 40 poles per mile, 2,400,000 trees. These also decay, and will require renewal. The demand for lumber increases at the rate of 25 per cent. per annum. The fences of the United States are now valued at 1,800,000,000 dollars, costing 98,000,000 dollars per annum for repairs and renewals. These are chiefly of wood. In 1871, 10,000 acres of forest were stripped of their timber to supply fuel for the single city of Chicago. 63,928 establishments, employing 393,378 persons and using material to the value of 310,000,000 dollars per annum, were engaged, in the year 1869, in manufacturing articles entirely from wood, in addition to the number of 7,439,840 persons partly employed on wood, and using annually wood to the value of 554,000,000 dollars. The estimate given by Mr. Hough, cited in the speech of Mr. Vogel, of 1,000,000,000 dollars per annum as the value of the products drawn from the forests of the United States, falls nearly one-third short of these enumerated items, without taking count of the consumption for the railways.

Timber for Fuel.

In England, and to some extent on the Continent, the comparative cheapness of coal has arrested the consumption of wood as fuel. But this protection is rapidly disappearing. The question of fuel is one which is pre-eminently decided on economical principles. The actual cost at which a given quantity of steam can be produced by the consumption of wood, or of coal, will be found to regulate the choice of combustible. As the price of coal rises, whether through increased cost in winning, or from that alarm as to the exhaustion of our coal-fields which has already produced a serious, and probably a permanent, advance in the market rate, the substitution of wood in part or in whole, becomes more practicable. It may be interesting to glance at the relative calorific value of the different species of fuel, as this will enable us to form a tolerably clear opinion as to the prospects of our supply. The lowest price that we have seen, in any of the works before us, quoted for timber for fuel in England is sixpence per cubic foot. But this includes a large proportion of the price for rent, or royalty, and profit. In the forests of Baden, where water-slides are used for the conveyance of large rafts of timber, "the Fortsverwalter is enabled," reports Captain Campbell Walker, "to fell, slip, and float the trees to a depot at a cost of 4 kreutzers, say $1\frac{1}{2}$ d. per foot all round." This cost is divided into felling, 1 kreutzer; slipping, $1\frac{1}{2}$; floating, $1\frac{1}{2}$. In Hanover, according to the same reporter, the price realised for the thinnings of the Beech woods, cut into billets, and piled ready for sale as fire-wood, is as low as $1\frac{1}{2}$ d. per cubic foot. The specific gravity of Beech is greater than that of average Fir, a cubic foot weighing 43 lbs. The calorific value

of a load of hewn billets will be thus fully one-fourth of that of a ton of coal. Forty cubic feet of Beech are sold for 5s. The best coal could formerly be obtained at the pit's mouth in many parts of the English coal-fields at 4s. 6d. per ton. Those days, no doubt, are over, but the comparison indicates the line where the cost of each of the two descriptions of fuel is at the minimum. The average price of our exported coal in the year 1869, just before the rise in price commenced, was 96s. per ton. In 1874, according to the last returns, it was 17'28s. per ton, and thus about equal to the calorific value of wood at 1½d. per foot. But we find the price of Fir in the Earl of Seaford's woods in Strathpey rated at 6d. per cubic foot, Larch being twice that price. The average value of the hewn timber imported into the United Kingdom in the year 1871 was 56'8s. per load, or 13'6d. per foot. It is clear, therefore that the price of coal must continue to rise until it attains something like four times the actual export value, before we are likely to see the introduction, on any large scale, of timber as a competing fuel. While the rate at which the forests of the United States, and of parts of our own territory, are being laid waste, is so rapid, and while the inducement to continue that waste, at least so far as the cutting of fuel and of lumber is concerned, is so great, it is certain that no power but that of legislation will be able to check the progress of destruction. The prospect that, at a time to be measured by tens of years, or even by generations, the woods of any country will be exhausted, will have but little influence on the dealer in fuel.

Trees and Climate.

In Eastern Ohio, William C. Bryant gives evidence that "it is a common observation that the summers are becoming drier, and the streams smaller; several rivers showing a considerable decrease in navigability during the last fifty years. The summers are hotter and the winters are colder." This is referred to the destruction of the forests along the tributaries of the Mississippi. Valencia, in South America, according to Mr. C. H. Granger, was formerly "situate about 1½ miles from a beautiful lake, which was surrounded by a dense forest. The trees were cut away, and in course of time the water receded to the distance of 4½ miles. The trees were afterwards replaced by others; and, in about twenty-two years, the lake returned to its original boundaries." "From all parts of the State" of Maine, according to the Report of the Commissioners of Agriculture for 1860, "comes up the same complaint of the diminished volume of water in the streams, occasioned by clearing up the forests and denuding the hills of trees. The snows are not so heavy nor so frequent as they were twenty or thirty years ago; and there is less rain in the summer. Many of the old trout streams of twenty years ago are now completely dry, and several parts of the State suffer more than formerly from drought. Snow covers and protects the ground with less regularity. . . . The first settlers in the counties of Kennebec and Oxford raised good Peaches in abundance. This fruit retired gradually from Maine, quitted Southern New Hampshire, lingered for a time in Massachusetts, and has finally been driven from all New England, except some favoured spots where shelter has been provided. . . . The same causes materially affect the more hardy Apple." Some twenty-five years ago the Danish island of Santa Cruz was a garden of freshness, beauty, and fertility. Woods covered the hills, trees were abundant, and the rains profuse and frequent. A recent visitor, who sought the island, with which he had been familiar in the time of its greatest beauty, for the sake of botanical study a year or two since, found a third part of it reduced to an utter desert. The short copious showers had ceased, and the process of desiccation was gradually extending over the island. An attempt to restore the former fertility by means of planting was made too late. One planter had set a thousand trees, but every one of them failed. "The island of Curaçao was," again says Mr. Hough, "within the memory of living persons, a garden of fertility, but now whole plantations, with their once beautiful villas and terraced gardens, are nothing but an arid waste; and yet 40 miles away, along the Spanish Main, shower down abundant blessings." The history of the forests of France would alone be ample to fill all the space at our command. The recent desolation wrought by floods is fresh in the memory of all. "By the destruction in France of a great extent of forests," writes Dr. Brown, "in order to replace them by cultivated fields, the temperature has become very irregular; heavy rains, storms, and dryness have each done their work upon the soil, and made crops every year more and more uncertain." In the Vosges, the destruction of forests has gone so far that agriculture has suffered, the soil has become arid, and inundations are frequent. In the Department of the Gard, in 1837, "no rain fell for nine months." Nismes, named from the forests which once surrounded it, is now amid an arid waste. At Beziers, the Agricultural Society reported in 1797 that the forest which once

sheltered the place having been destroyed, the loss of the Olive crop was the consequence. The authorities of the Isère represented, in 1793, that the destruction of the forests had altered the temperature, augmented dryness, and seriously affected the crops. From Provence, from the valley of the Moselle, from that of the Haute Garonne, from the Hérault, and from the Eastern Pyrenees, come complaints of the same nature. The regular rainfall has been diminished, the temperature has changed and become uncertain, and partial and irregular storms have proved curses rather than blessings, wherever the forests have been ruthlessly swept away.

So fully are these facts regarded as established in Switzerland, that in the Social Science Congress at Berne, in 1865, the question was raised as to the means of establishing a common legislation between countries watered by the same rivers, in order to protect their respective interests, by the maintenance of the mountain forests, and the greatest possible attention is now paid to the subject by all the Cantonal Governments of Switzerland. It is hardly necessary, after so much evidence as to the consequences of that destruction of forest which is now so actively going on in many parts of the Old World as well as of the New, to follow Prof. Laurent, of Nancy, in tracing the desolation which has been brought on the former homes of teeming human life in the East by the same cause. Babylon and Nineveh, Thebes, Memphis, and Carthage, now waste and even pestilential, were formerly the very lives of human life. The remains of conduits, canals, cisterns, and pools throughout Palestine, and especially through the now desert country east of the Jordan, are such as to explain the accounts on record of the former population of these regions. So thorough has been, not only the change of climate, but the denudation of soil, caused by the cutting down the Olives, Palms, and other trees of Palestine during the Roman war, that it would be impossible to attach any credit to the most venerable accounts of the former fertility, beauty, and population of the Holy Land (its brooks and fountains gushing out of valleys and hills, being now replaced by bare and solid rock), without the knowledge that we have acquired of the fatal effect of the destruction of timber.

Forests on the Continent and in England.

Into the special products of arboriculture, indeed, we must forbear now to enter. The subject is full of interest. Among the 3000 species of wood of which specimens were shown at the Paris Exhibition in 1867 were to be found samples of the most varied beauty; of ivory smoothness and purity of colour and texture, or streaked, pencilled, mottled, ocellated, and marked with every imaginable caprice. Arboreal products, apart from wood, are numerous. Such are the bark of the Cork-Oak in Portugal, and that of our own Oak coppices and woods, stripped in spring for the use of the tanners. Such are the gums from Zauzibar, from Angola, from Senegal, and from Mogador; the resin from the forests of the Landes, the caoutchouc from the banks of the Amazon. The physiognomy of trees, the mode in which each well-grown tree tends to fill out the sketch given in the venation of the leaf; the effect produced on landscape by the social or solitary growth of trees; the wonderful glow of the flowers of some tropical species, as in that crimson-petalled and glossy-leaved tree that lines the banks of the Parana; the variety of form in the same species, according to locality, as in the Olive, which, from the size of a Carant-bush on the hills near Marseilles, rises to that of a lofty forest tree by the shores of the Ionian Sea; are subjects on which we have no space to dwell. Nor can we pause to speak of the dangers and foes of the forester; how broad spaces should be left as barriers against fire, while at the same time any rash opening cut in a forest may admit the winds which overthrow the trees, or the sun which strikes with fatal energy on their bark. Insect and other animal foes lie in wait for every symptom of weakness—the bark-beetle, the wood-beetle, the squirrel, the rabbit, the field-mouse, the wild hog, the deer. The insectivorous and carnivorous birds are the great allies of the forester, paying ample rent for the shelter afforded by the forest. Against drought, the great foe to agriculture, the forests can protect not only themselves but the neighbouring country. Their only irresistible foe is man—chiefly seen in the guise of the squatter or of the lumber dealer. The contrast that is presented between England (notwithstanding the vast importance of her colonial forests), and France and Germany, in respect to the education provided for the forester, is not the least striking feature of this interesting subject. We have seen how to gain elementary knowledge for the management of the Indian forests it has been necessary to send out officers to study in France and Germany. In those countries, Mr. Webber remarks, "Forestry is one of the State professions of the highest scientific character, and regularly filled from the well-educated class who are specially trained for the purpose." In France there yet exist 2,700,000 acres of State forest, in the conservation and management of which

THE KITCHEN GARDEN.

LATE-SOWN HORN CARROTS.

We have just finished taking up our crops of late-sown French Horn Carrots, as they keep fresher and better in the ground till February. In severe winters, a little dry litter is thrown loosely over them during the continuance of sharp frost; but, with us, that has not been necessary this season, as the only severe frost we have had was accompanied with several inches of snow, which formed a sufficient protection. They were sown the first week in August, on a warm, dry, south border, after a crop of early Potatoes, the only preparation the ground received being a liberal dressing of soot mixed with a small proportion of salt, sown broadcast over the surface, and hoed in deeply. The surface was then raked level, drilled drawn, and the seed sown in the usual way. In due course the young plants appeared, and were thinned out from 1 to 2 in. apart; to be still further thinned when large enough for use, by constantly drawing the largest. Occupying a warm site, they continued growing till Christmas, and are now as fresh and sweet as young Carrots. If left in the ground longer, the roots would have thrown out fibres, which would have injured the flavour. In places where the summer crop is attacked by maggots, a larger sowing might be made in August to lift fresh now, as I have found the late-sown crops do not suffer so much injury from insect enemies, probably one reason may be the earth is so warm, the seeds quickly vegetate, and the young plants rapidly grow away from their foes; at any rate, where there has been a difficulty in providing good Carrots for use after Christmas, this plan is worth an extensive trial. In old gardens, that have long been under cultivation with little change in the mode of culture or variation in the crops, and where stable-manure, with the refuse vegetable substances usually accumulating about a garden, has formed the only manure supply, insect enemies in the grub or larva state are likely to be abundant. In such cases a very slight acquaintance with the use of salt, gas-lime, lime, or soot will convince anyone of their value, when judiciously applied, either as top-dressings to growing crops, or dug into the land in winter. A mistake can hardly be made in the application of soot, but salt and gas-lime may be used to excess, especially where it is necessary for one crop to follow another in rapid succession; and this, perhaps, is one reason why salt is so little used in private gardens. I think it will be readily conceded that in applying salt to land, the nature of the crop following should be considered, as well as the nature of the soil, whether dry and porous or retentive; and, unless something is known of its chemical analysis, it is far better to proceed tentatively; but, at any rate, from $\frac{1}{4}$ to $\frac{1}{2}$ lb. per square yard may be used with safety on all porous soils, for nearly all crops except Potatoes; and for Asparagus, Seakale, and Onions double the quantity may safely be used. There is one thing in which gardeners might take a lesson from farmers, and that is in their applications of stimulating manures. I am convinced that, even where other kinds of manures are abundant, in a climate like ours, if our efforts to get things good and early were aided by the application of some concentrated stimulant sown with the seeds in very small quantities, just to give the young plants a fair start, very few failures need be dreaded: I will just give one instance that has a bearing upon this. For several years I had the greatest difficulty in preserving the earliest crop of Turnips from the fly—so persistent and destructive were their attacks. I tried all sorts of surface-dressings, but success was far from perfect till I adopted the expedient of mixing salt, guano, and wood ashes together, the latter far in excess of the two former, and strewed the mixture thinly along the drills on the top of the seeds. I had read that guano and salt would destroy the vitality of all seeds with which it came in contact, and, therefore, I proceeded cautiously; and I can only say that I have not since sown the seeds thicker than formerly—indeed, not so thick—and I have always plenty to hoe out. I believe the larvæ of the flies are in some way attached to the seeds when sown, and the small quantity of salt ensures their destruction before they are developed, whilst the guano pushing the young plants on so rapidly they soon grow away from the

£500,000 is annually expended; the returns amounting to £1,740,000. Prussia has 6,200,000 acres; Bavaria, 3,294,000 acres; Hanover, 900,000 acres; Saxony, 394,000 acres; Austria, 2,230,000 acres; the Grand Duchy of Baden, 72,500 acres, according to the report of Captain Campbell Walker, who spent four months and a half in a tour through these provinces, at the instance of Dr. Brandis, for the purpose of education as a forest officer in India. Another statement taken from Bernhardt's "Forststatik," for Prussia, Wurtemberg, and Baden; and from the "Tharander Forstliches," for Saxony; and from the "Forststatistische Mittheilung," for Bavaria; is tabulated by Captain Walker as follows:—

Name of State.	Area of State Forests in English Acres.		Yield of col. 2. Cubic Feet per Acre.
	Productive.	Non-productive	
	1.	2.	3.
Prussia	5,836,100	686,175	34.5
Saxony	378,655	16,614	72.6
Bavaria	2,079,835	238,738	63.0
Wurtemberg	469,087	—	84.7
Baden	212,770	18,817	69.8
Austrian Empire	1,576,699	653,347	41.0

The total acreage of the twelve Royal Forests and Woodlands in England, according to a return to the House of Commons in 1863, was 112,376 acres, of which 51,606 were actually under wood. Of these the New Forest, with a woodland of 22,319 acres, had a revenue, in 1871, of £12,034, and an expenditure of £7790. Dean Forest, with 14,754 acres under wood, earned £10,838, at a cost of £7878. High Meadow Wood, lying in the counties of Gloucester, Monmouth, and Hereford, purchased under the provisions of Act 57 Geo. III. for the growth of Oak and Fir, contains 3359 acres, all under wood. The revenue in 1871 was £5176, the expenditure only £1827. The receipts of the whole 51,600 acres, in 1870-71, are reported by Captain Walker at £37,390, the outlay at £22,230. In 1849 the timber in the 40,000 acres of plantations made since 1808 was estimated at the value of £1,087,777, and the value of the same when arrived at maturity was estimated at £10,000,000. Compared with the French forests the revenue is 14.46s. per acre in England, against 12.6s. in France; but the expenditure is 8.22s. per acre here, and only 3.7s. per acre in France; the net revenue in the former country being 6.24s. per acre, against 8.9s. per acre in the latter. Thus the financial outcome of our forestry is better than might have been expected from the absence of regular education for the duties of the forester. It is rather in the general destruction of timber through wide districts of England, and in the wholesale devastation of our colonial forests, that the evil results of our want of study are displayed, than in the actual results of our home State forestry. The net revenue of the Bavarian forests is stated at 8.7s. per acre, and that of the Saxon forests at 12s. 6d. per acre, but in Prussia and Austria the profit to the State is far less considerable. The report of the Vicomte de Bonald points out, with great justice, that the financial returns of forests are so far subordinate to the necessity of a culture that will maintain an adequate supply of fuel, and more especially of timber for construction, that the administration of the forest demesnes should not be under the control of the Minister of Finance.—"Edinburgh Review."

Curious Effect of Frost on Trees.—A correspondent of the "Times," writing from Helsingborg the other day, says:—Part of the south coast of Sweden is at present the scene of a phenomenon so rare that a brief description of it may perhaps be of interest to those to whom such freaks of Nature are interesting. During the last seven days, simultaneous with a very dense fog, there prevailed such a severe frost, that every tree and bush were crystallised, in many cases 4 in. The crystallisation differed, however, from any similar phenomenon I had ever seen before in other parts of the world, inasmuch as it was confined to one side of the objects crystallised, and was formed in so striking a resemblance to the feathers on a quill that the forests, gardens, and avenues, seemed composed of a mass of gigantic quills or plumes. When the fog cleared away the sun shone full out, and a brisk breeze sprang up, the iridescent dazzle of the forests, and groups of waving crystal plumes were beautiful beyond description. Nothing similar has been witnessed in Southern Sweden by even the oldest inhabitants.

Counting the Years of a Tree.—L. H.—A good way is to have the section planed, then fix a straight-edge on it, from the centre to the bark, and mark with a pencil the place where the edge of the straight-edge cuts the rings; you can then readily count the marks on the straight-edge. This method is, of course, only approximately correct. It is sometimes desirable to varnish a piece of wood with close rings when evidence as to its age is sought for in this manner.

few insects that may ultimately struggle into life. This, however, opens up a wide field for discussion that can only just be glanced at in a short paper. EDWARD HOBBAY.

American Potatoes Degrading.—Like Mr. Groom (see p. 124), I have not found the American Potatoes degenerate when grown in this country. I have grown the American Early Rose for some years, and have found no deterioration in it, but I have now discarded it, owing to its bad flavour. The Extra Early Vermont, a newer variety of the same section as the Early Rose, is another productive kind, but not of good quality as grown in the strong soil of the garden here. No doubt soil and seasons have some effect on the qualities of these American varieties, and the only sort I find, when grown year after year, worthy of a place in my collection is Climax; but, if Snowflake, sent out last year, be at all good for the table, it may be grown with advantage on account of its fine shape and good cropping qualities. I see that Potato seed, grown in America and raised from their sorts, is advertised for sale in this country, but I should rather prefer sowing seed from good sorts here if crossed with American varieties.—WILLIAM TILBEY.

Forcing Asparagus.—For this purpose strong, healthy, well-developed crowns and roots should be selected, which at four and five years old are at their best for forcing. They start more readily into growth, and, according to a writer in "The Gardener," are more remunerative at that age than younger or older. The first roots placed in heat on the 1st of November last are not yet exhausted. They were forced in the bed of a Cucumber-house, where there is a bottom-heat pipe underneath, with about 1 ft. of broken bricks between it and the soil. About 2 in. of soil were spread over the surface of the bricks, and on this the roots were closely packed; 3 in. of soil were placed over the crowns, and the whole was thoroughly watered with tepid water. The heat in the soil remained steadily at 50°, and the air temperature between 60° and 65°. Most of the stalks have been cut when 12 in. high, and being fully exposed to light, they were quite green. When allowed to grow longer Asparagus becomes less tender, and to cut it before it grows to this length is extravagant. It is always cut over at the surface of the soil; and although an inch or two might be got underneath, it is always tough, and when cooked is deficient in flavour. A few of the smallest stems are allowed to grow tall when they branch out, and the delicate tops are cut and used with excellent effect as greenery amongst cut flowers. Asparagus can be much more profitably forced in structures of this kind during the cold winter months than in frames set on a hot-bed. It does start away freely in the latter at first, but the heat soon declines, and a good deal of what it ought to produce is consequently lost. Manure frames do very well with which to begin forcing about the middle of February or beginning of March, so that when the heat declines, there is enough of warmth in the air to bring up all there is to come. In whatever position Asparagus is forced, the stems should be fully exposed to light and air throughout their growth, otherwise the flavour will be deficient.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Importance of Heeling-in Broccoli.—Many practical gardeners will endorse Mr. Baines's statement (see p. 124) in reference to this matter. Here, with us, in severe winters, Broccoli or no Broccoli is simply a question of partially lifting the plants and laying them down, heads northward, about November. We tried to do without lifting one season, and lost half our plants—the lifting prevents us losing any.—W. S. G. H. A.

Potatoes for Exhibition.—The best four sorts in each section at the late Alexandra Palace Potato Exhibition were.—Of white Rounds—Model, Rector of Woodcock, Porter's Excelsior, and Early Market; of coloured Rounds—Red Emperor, Scotch Blue, Blanchard, and Early Oneida; of white Kidneys—Waterloo, Snowflake, Lapstone, and Excelsior; and of coloured Kidneys—Bountiful, Extra Early Vermont, Purple Ashleaf, and Salmon Kidney.—A. D.

Large Seeds Best.—Looking upon the plumpest, best developed, and consequently largest seeds as the best, I have, like many other gardeners, been in the habit of selecting our Melons, Cucumbers, Beans, and other large seeds for planting, because we have long known that they produced the best plants, but, though the rule will, no doubt, hold good with regard to small seeds, such as those of Turnips, &c., (see p. 124), selecting is not worth the trouble. Seed is not so very dear; therefore, sow thickly enough, allow for vermin making "a selection," and in due season thin out to the best plants.—J. S. W.

Early Market Garden Potatoes.—The best Early Kidney for market purposes is Myatt's Prolific Ashleaf, and the best early Round is Fenn's Early Market. This kind, which is new, is a first early, and has an exceedingly short top, which does not interfere with the growth of a succeeding green crop. A fine successional Kidney for market purposes is Dawes' Matchless, as its large white mealy tubers are fit for sale and are in great demand even before ripe. It is highly esteemed as a market kind in West Middlesex. It is probable that the new American Snowflake, which is an early second early, will shortly become a popular market variety.—D.

THE FLOWER GARDEN.

HARDY FLOWERS NOW IN BLOOM.

SOME of the choicest gems of the early year, Iris (Xiphion) Histro for example (see p. 29), are already over, and their places supplied by others. Iris reticulata is pushing up odd blooms here and there in Mr. Barr's grounds at Tooting, and a few warm bright days would bring out many more. Of this Iris there are two distinct forms—one with deep bluish purple flowers, the other red or bronzy; both are, however, very beautiful, and should have a place on every dry sunny border. Anemone blanda, one of the earliest of blue flowering plants, is cropping up here and there, but it wants warm sunshine to enable its flowers to expand properly. This is one of the prettiest of our early flowers, and, fortunately, one which is easily propagated by cutting up its tubers in the autumn. In order to see the beauty of these Irises, the blue Anemone and its allies, the Hepaticas, to the best advantage, they should be planted in patches here and there on the herbaceous border, or used in quantity to fringe the edge of the rockery or rock-garden, and with them should be associated the never-failing winter Aconite and a few of the earliest yellow Crocuses for contrast. How rarely do we see Snowdrops and Daffodils sprinkled on the green turf in outlying portions of our gardens, and yet how beautiful they look in many old country orchards and paddocks? The hardy Cyclamens are in good condition just now, especially the following—viz., *C. vernalis*, a kind with flowers of the most vivid magenta; *C. ibericum*, *C. Coum*, *C. Atkinsii*, and other varieties of these kinds; while *C. hederastolium*, and its variety *C. gracum*, although not in bloom, are very ornamental, inasmuch as they carpet the bare earth with their large and beautifully marbled leaves, and nothing can be prettier than natural-looking patches of these plants in the rock garden or elsewhere with a few Snowdrops or Crocuses dropped in irregularly among them, but not in rows or formal patterns, which would be unsightly. Snowflakes and Snowdrops are everywhere pushing through the ground, the common *Galanthus nivalis*, however, being the only one in full flower. *G. Elwesii*, *G. Imperati*, and the Crimean Snowdrop (*G. plicatus*), are, however, showing colour. The common Snowdrop, lovely as it is in many sunny country orchards among the Grass in early spring, is even prettier, if possible, when plucked and made up into little posies; indeed, a little bunch of Snowdrops and Violets forms the sweetest and most tasteful of all button-hole bouquets. As regards pearly whiteness few flowers can compare with the Snowdrop: place one beside the Lily-of-the-valley or the whitest *Odontoglossum*, and they look creamy-white or actually yellow. Crocuses are now beginning to make their appearance in quantity. The lovely fawn-lilac and purple-flowered *C. Imperati* is already very beautiful, as is also lilac *C. Sieberi*, which is one of the most distinct of all the early-flowering kinds, and there are, likewise, forms of the common yellow and common purple (*C. vernus*) showing colour.

Christmas Roses are still showy, and for cut flowers are invaluable, for if the flower-stems be cut when the first blossom expands, they open out all their flowers well in water indoors. *H. Olympicus* is showing rich maroon-coloured flowers, along with those of *H. niger*, *H. maximus*, and *H. purpurascens*. Christmas Roses seem to be in great confusion as regards nomenclature; for example, the beautiful, large flowered form recommended by Miss Hope as *H. maximus* is by Herr Max Leichtlin (see p. 137) referred to *H. abchasicus* of Robert Brown. I find *H. abchasicus* is a species described by A. Brown (see *Otto Garten-Zeitung*, 1858-1). If I mistake not, this *H. abchasicus* is a Hungarian plant, of which there are two well-marked forms, one with purplish flowers, hence named *H. purpurascens*, and another with nearly white flowers, which is grown in gardens under many different names, and, together with *H. guttatus*, it has given rise to a beautiful race of very showy striped and spotted hybrids in the Botanic Gardens at Berlin. These new forms do not appear to be yet introduced to our gardens—a fact to be deplored, as they would form charming companions to the white and pale rosy form of our common Christmas Rose. I mention these here so that all who desire them may make

inquiries about them at the Berlin Garden, and I hope some botanist, who appreciates the early beauty of these Hellebores, will take them in hand and unravel the now confused and confusing synonymy. This is rather a dull season for aquatics, but one at least is in bloom, namely, *Aponogeton distachyon*. Of this I gathered several fresh spikes from plants in Mr. Parker's nursery at Tooting a day or two ago, and they are now quite fresh in a glass of water. There were dozens of fine spikes on the plants which have been blooming all the winter in the running water of a shallow ditch, and are quite uninjured. For cut flowers this plant deserves attention—its white bracts and black anthers contrasting together very beautifully, and for grouping in moist

type of the more recent introductions in the same section of the genus, which agree with it in forming radical tufts of narrowly linear or linear-lanceolate channelled foliage, from 1 to 2 ft. or more in length, with parallel nerves, and spiny at the margin, whilst from the centre of the tuft arises a tall paniculately branching stem, bearing numerous rather small heads of flowers. In *E. orbunum* the foliage is broader than in the preceding species, and forms handsome effective tufts. In *E. padanifolium* the leaves are twice as long as in *E. orbunum*, more uniform in breadth, and more erect in their growth. In *E. Lascaurii* the foliage resembles that of *Yucca angustifolia*, and is less spiny than the species just named; the flowers are also said to differ in being of a reddish colour. All these plants appear to be hardy in dry soils, with a covering of dry leaves or straw in severe weather, but they are likely to perish in wet soils

and may advantageously be cultivated in large pots, the seedlings being first pricked off in small pots, and shifted successively into larger ones, as growth advances. Abundance of moisture during summer and autumn is an essential feature of their treatment. They are natives of southern Brazil, or of the Argentine provinces.—W. THOMPSON, Ipswich.

Plant protectors.—In our changeable climate it is of the greatest consequence to plants to preserve them as much as possible from injury caused by these changes, and above all to supplement the coating of snow, which in the colder regions of the world protects plants from the injuries of exposure. I tried the refuse of Cocoa-nut matting, but it was unsatisfactory. It then occurred to me that there was no non-conductor like hair, and no cheaper commodity. The hair dressers throw away all their hair which at present is useless. Quantities of horse-hair (the result of clipping) is also thrown away. I use both with great advantage; it makes what I call false snow, protects the small plants, and with a little dexterity may be arranged to protect the larger plants and the bases of delicate trees, and entirely prevents their being injured by frost; and, amongst other advantages, slugs cannot travel in it.—GEORGE LEIGH, High Leigh.—P.S. I think bulbs surrounded by hair might be benefited, and though I have not tried it, many sorts of seeds dropped in hair and covered with a thin layer of earth might be more easily propagated than at present.

Early Flowers at Bitton.—The season is rather backward, but I have noted the following plants in flower to-day (Feb. 1):—*Crocus messiacus*, *asiaticus*, *Imperati*, *lucigatus*, and *vernus*; *Primula veris*, v. double and coloured, and *polyanthus*; Common

Dwarf Calceolaria.

Dwarf Herbaceous Calceolarias.—MM. Vilmorin, Andrieux, & Cie., of Paris, have lately introduced a dwarf strain of Calceolarias. They are described as remarkable for a dwarf, bushy habit, with the flowers arranged in a large and thickly-set bouquet, the blossoms being of first-rate quality as regards size and markings.

Eryngium orbunum.—Under the head of *E. Leavenworthii*, reference was made to several species with ornamental foliage recently introduced to gardens, and their decorative value is so considerable that some special notice of their merits seems desirable. The *E. bromeliæfolium* is now pretty well known, and it may be taken as the

F. W. B.

NEW PLANTS, &c.

Snowdrop, and its double variety, and *Galanthus Elwesii*; *Hepatica*, red, white, and blue; *Mahonia japonica* and *Aquifolium*; *Garrya elliptica*; *Viburnum Tinus*; *Erica hercacea*; *Leucojum vernum*; *Filbert*; *Ulex europæus*; *Tussilago fragrans*; *Helleborus niger* and *maximus*, *cupreus*, *orientalis*, *kamskatkionis* (?), *atrorubens*, *guttatus*, *lucidus*, *antiquorum*, and *olympicus*; *Arbutus Croonii*; *Chimonanthus fragrans*; *Xiphion Histrice*; *Eranthis hyemalis*; *Violet Czar*; *Cyclamen Coum* and *ibericum*; *Iberis semperflorens*; *Daphne indica rubra*; and the naked flowered *Jasmine* (*Jasminum nudiflorum*).—H. N. ELLACOMBE, *Bitton Vicarage*.

A Misnamed Primrose.—Allow me to protest against the loose way in which "A. D." uses the name *Primula altaica* in THE GARDEN. He is thinking of one of the coloured varieties of the common Primrose, but this does not call it, to the confusion of those who know nothing of those things, and the annoyance of those who do—for the difficulties of plant nomenclature are sufficiently formidable without adding unnecessary confusion by wrong names. It has been shown again and again in THE GARDEN that the plant meant by "A. D." is simply a variety of the common Primrose, and that it has no claim whatever to that of *altica*, which belongs of right to another species.—V.

Large Christmas Roses.—Christmas Roses were never finer than they are here this season. I measured one bloom yesterday (Jan. 31), and it measured rather more than 4 in. across. One plant is producing some forty blooms. Christmas Roses are said to object to being transplanted, but all my plants now in such fine bloom were lifted in September and planted in good loam and peat on the edge of a Rhododendron bank. For the decoration of rooms nothing can look better than vases of Christmas Roses fringed with leaves of *Hedera maculata variegata*. Are my Hellebores the true *Helleborus Major* or *maximus*? The fact that they have but lately come into bloom would seem to indicate that they are not; but does the true *maximus* produce larger flowers than those which I have described? They resemble blossoms of a beautiful white Clematis.—HERBERT MILLINGTON, *Bromsgrove*.

The best Phloxes.—Some of the best of the herbaceous Phloxes will be found among the following:—White Lady, the best of the whites in the decussata section; Madame A. Damesil, white with purple eye; Madame Maisonnette, white with crimson eye, and somewhat flushed; Mademoiselle Marie Saison, white with purple eye; Coquette du Parc de Neuilly, white with bright purple eye; Eugénie Immer, white with delicately-tinted purple eye; Comtesse de Turenne, white with delicate purple eye, a very chaste-looking flower; coccinea, a bright but dark carmine crimson; Resplendent, carmine-scarlet; Lothair, light salmony-scarlet with dark eye; Madame Caillard, bright salmon with dark eye; Rivière, fine salmon-scarlet with dark eye; Mons. Jigne, rosy-salmon with dark eye; Mademoiselle Hermine de Turenne, purple crimson; Madame Godfrey, bright purple; M. Galdensharoh, rosy-pink with dark eye; Menotti, lilac with white eye, very distinct; and Madame Darenne, lilac with broad dark purple centre. These are all fine, of good habit, and striking colours.—"Florist."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Transplanting Rose Cuttings.—Following the advice given by you last year (see Vol. VIII., p. 22), I put in several cuttings of *Rosa* in July and August. These took exceedingly well at present, and are making beautiful shoots. I should be glad to know when they should be taken up and planted in the borders with the other Roses. May they be moved this year, or would it be wiser to wait till next? They are in the open ground.—D., *Leicestershire*.

***Primula vulgaris grandiflora*.**—According to Mr. Niven P. *altica* is in future to bear this name; but, looking at its charming mauve hue, it seems to me that the title of *P. vulgaris* *cerules* would have been more suitable. It is, however, too late now to suggest such an amendment. From a cross with this kind and *P. vulgaris auriculiflora* I obtained some lovely seedlings, possessing violet-purple and intermediate tints, that are most welcome.—A. D.

***Myosotis Imperatrice Elizabeth*.**—This is a very beautiful little hardy plant. I believe it is a hybrid from *M. azorica*, of which it retains the deep ultramarine hue, but it has the free habit and hardiness, at least in this mild climate, of *M. sylvatica*. At first it was considered tender, but it has stood out in the open border without any protection for the last three winters. It is easily increased by cuttings.—SALMONICERS.

Destroying the American Water Weed. (J. Y.)—Empty the pond, and rake it out. Swans will help to keep the pest down. Nothing but repeated attention will keep it within bounds. After a time, however, its growth is often less vigorous than when it first appears, owing no doubt to its exhausting the soil of its more special requirements. It will, probably, in time be re-placed in its turn by other plants, as, indeed, we have noticed in one piece of water already.

***Celastrus scandens*.**—This climbing North-American shrub, related to the *Euonymus*, produces masses of orange-scarlet fruit in winter, and, if properly grown, may be made to present a brilliant display. It is popularly known in America as Bittersweet or Wax-work.—W.

***Wallisia princeps*.**—A showy Gentianeaceous plant, known also as *Lisianthus princeps*, and a native of the Columbian Alps and also of New Grenada at an altitude of 10,000 to 12,000 feet.—"Gartenflora," t. 839.

***Crocus veluchensis*.**—A very showy purple-flowered *Crocus*, a native of Greece and Transylvania. It is a very rare plant in cultivation, and has flowered with the Rev. H. Harpur-Crewe, who received it from Herr Max Leichtlin. Mr. Baker remarks that Col. Trevor Clarke sent a flower of *C. vernus* of nearly exactly the same colour. This plant is said to differ from *C. Sieberi* in having a purple throat like the segments instead of a yellow one.—"Botanical Magazine," t. 6197.

***Carica candamarcensis*.**—A graceful little Papaw tree, a native of the Andes of Ecuador, and raised by the late Mr. Hanbury from seeds sent home by the late Professor Jameson, of Quito. It flowered in an open border at Clapham in 1874. Mr. Spruce calls this the common Papaw of the Andes, where it is grown for the sake of its edible fruit up to an elevation of 9000 feet. The flesh is white, not yellow, as in the common Papaw. It has been introduced to the Belgian Nurseries, and has recently fruited in English gardens.—"Botanical Magazine," t. 6198.

***Dendrobium amenum*.**—A very pretty little slender-stemmed Dendrobe, bearing two or three-flowered fascicles of white flowers, each segment being tipped with lilac-purple. In general appearance, this plant very closely resembles the old *D. transparens*, and is very distinct from *D. primum*, which is, indeed, one of the best forms of the *D. Pierardi* group. *D. amenum* has been introduced from the Himalayas by Mr. W. Bull, and is said to grow at an altitude of 5000 feet. It has been shown repeatedly at the metropolitan exhibition, by Mr. Bull during 1874-5.—"Botanical Magazine," t. 6199.

***Calochortus citrinus*.**—This is a showy-bloomed Californian species, that bears flowers fully 3 in. in diameter, the petals being somewhat rhombiform of a deep orange-yellow colour, and very hairy. The species previously known are—*C. venustus*, *C. Leichtlinii*, *C. Gunnisoni*, *C. splendens*, *C. macrocarpus*, and *C. luteus*, and of these *C. venustus* is by far the most attractive, and, like the present species, it has recently flowered with Mr. G. F. Wilson, at Heather Bank, Weybridge. *C. citrinus* is described as being somewhat intermediate, between *C. splendens* and *C. luteus*.—See "Botanical Magazine," t. 6200.

***Decabelone Barklyi*.**—This is a south African species, quite distinct from *D. elegans* (see "Botanical Magazine," t. 6115), which has large pendulous flowers. In habit it reminds one of the columnar Euphorbias, more than any of the *Stapelias* to which it is nearly related. The tufted seven and eight-angled stems are 5 or 6 in. in height, the bell-shaped five-lobed flowers being borne erect in pairs, and of a soft yellow colour, profusely spotted with brown. It will be a useful addition to the collections of succulent *Asclepiads*.—"Botanical Magazine," t. 6203.

***Nicotiana Tabacum* (var. *fruticosa*).**—One of the numerous forms of the common Tobacco plant, originally brought into cultivation from South America, and now popular in our gardens during the summer months as decorative plants. It grows about 2 feet or more in height, having clammy leaves, rarely over a foot in length. The flowers are in terminal panicles, comparatively tubular, and of a pale rosy colour.—"Botanical Magazine," t. 6207.

***Cucumis sativus* (var. *Sikkimensis*).**—This is the supposed hybrid Melon-Cucumber, figured and described in THE GARDEN (p. 235, Vol. VIII.), and though very distinct in general appearance, it is only a form of the common cultivated Cucumber of our gardens (*C. sativus*), which its leaves and flowers closely resemble. The fruit is about a foot in length, and thicker or more swollen than in the common Cucumber, and, although the young fruits are prickly, these prickles become nearly obsolete or reduced to blunt tubercles, when the fruit attains its full size. Its skin is of a warm brown colour, and when ripe it crackles all over like the "netting" of a Melon, and the white inner coat beneath shows through and adds to the ornate character of the plant. The origin of the common Cucumber is by no means well known; Dr. Hooker and M. Naudin both consider it that is a cultivated form of, or, rather, that it is a species evolved from, *C. Hardwickii* (Boyle), a native of the Himalayan Range, where it is found from Ramoan to Sikkim.—"Botanical Magazine," t. 6206.

NEARLY 200 tons weight of Orange blossoms are used in the manufacture of perfumery in the town of Niseleson.

NATAL FRUITS AND VEGETABLES.

A WRITER in "Fraser" gives an account of the fruits and vegetables of this colony, which is more candid and trustworthy than most accounts that are printed respecting exotic fruits. Of the fruits in Natal the Orange ranks first and foremost. Most people know that the Orange tree is one of great beauty, though the stunted hot-house specimen in this country can scarcely bear comparison with its more fortunate relative that lives always in open air, in a climate that suits it, and which spreads at will its lovely dark leaves, and sweet-scented flowers, and profusion of golden fruit. I think there is nothing prettier than a well-grown Orange grove, with the trees full of flowers and fruit together. They are trees that require little care; an occasional pruning keeps them in very good order. There are several different kinds of Orange in Natal. The most common are of a large size, and have a much deeper and tougher lining to their coats than those that are imported into this country; but they are deliciously sweet and juicy in spite of their unpromising exterior. It is surprising what a difference there is in the flavour of an Orange just picked and in one that has been kept; they seem to lose half their taste when they have been lying about for some weeks. Besides the common kind of Orange, they have the Natje, or Mandarin, a small flat fruit, with much juice, but of excellent flavour. It seems a thousand pities that the Oranges cannot be turned to more account. A good many are sold, but quantities lie about under the trees and are wasted. They are very good preserved whole, or made into marmalade. It is a mistake to suppose that it is necessary to have Seville Oranges for that purpose; the common yellow kind does just as well. Lemons in Natal are by no means so satisfactory as Oranges. They grow to a large size, and are nearly all rind and tough white lining, with very little juice. Citrons are plentiful, but cannot be considered a useful fruit—only good for candied peel. Limes flourish, which are nice in hot weather to make refreshing drinks with, and I think they come to as great perfection in Natal as they do anywhere.

Bananas deserve to be mentioned next. The Banana grows to a good height, and is covered with large limp leaves that hang down, some a foot or more in length; which leaves have a way of rustling when the wind blows through them, like the ghost of a lady in a stiff silk gown. The fruit is mealy, ispid, and of a slightly Pear-like flavour. A taste for it is acquired; few people like it at first, but it improves on acquaintance, and children get very fond of it; and it is good for them, being a wholesome and nourishing fruit; indeed, it may be regarded more in the light of food than ordinary fruit, for it is so satisfying that after a good handful of Bananas one would feel one had had a tolerably substantial meal. They are excellent also cooked in the form of pancakes or fritters. Plantains are a coarser and larger species of Banana, and to my mind inferior.

There are three kinds of Guava in Natal. They are a coast fruit. I cannot say that I have seen them grown much about the part I know best—the neighbourhood of Maritzburg—but at the Chace, a beautiful garden in the Town Bush Valley near Maritzburg, they have the three sorts. The largest kind is about the size of an ordinary hen's egg. It is covered with a thin yellow skin, and the inside is pink and pulpy. It smells very much like a mouse, which is not so pleasant; but if one holds one's nose tightly and eats it very quickly it really is not bad, and rather refreshing in hot weather. The small yellow Guava is a poor imitation of its larger relation, and somewhat flavourless, but is without the mouse-smell. The little red Chinese Guava is delicious; too much cannot be said in its favour. In shape and size it is not unlike a small Medlar, but of a deep crimson colour. It has a slight taste of Strawberries, combined with a delicious flavour peculiar to itself. It is altogether excellent. It is of this Guava that the far-famed jelly is made; and I think that prepared in Natal quite equals what we get from the West Indies, and it is far cheaper.

Loquats are an agreeable and useful fruit. They grow in thick bunches, on a handsome, well-shaped tree, that in its height, and the colour of its leaves, reminds one of the Laurel at home—but the leaves are smaller. The fruit is about the size of small yellow Plums, but quite unlike any Plum in taste. It is full of juice, and has a partly sweet, partly acid flavour. It partakes a little of the general insipidity of the fruits in the colony, but after the first disappointment one gets used to that. It makes good jam, and capital tarts, so it deserves some praise. And the trees are always ornaments to a garden, for they retain their beautiful leaves all the year round.

The Grandilla is the fruit of a species of Passion-flower, which flourishes like a weed in Natal; but it does no harm, excepting, perhaps, as a harbinger for snakes, which are fond of curling themselves up among its thick leaves, and people need to be cautious when they are picking the fruit. The Grandilla requires support, and it very quickly finds its way from one tree to another, around which it

wines, ornamenting it with its lovely starry flowers and pretty fruit. The fruit is green when young, but as it ripens, gradually changes to a deep purple. It is egg-shaped, and one eats the top off, and eats it just as one would an egg. It is full of small seeds, pulp, and juice, and, besides being very good in its natural state, makes excellent jelly.

The Mango I think quite unpleasant, but as many people think otherwise, I must not run it down. It is like an enormous Plum, and has a taste of turpentine combined with various other flavours, and is so extremely sticky, that I have heard that in India, where it is thought a great deal of, people are in the habit of eating it in their baths, so as to get rid of the sticky effect as speedily as possible.

Pine-apples flourish abundantly on the coast; they will also grow higher up, but they do not do so well, as they require so much heat. A large quantity are brought to Maritzburg from Durban for sale, and can be bought for about fourpence each in the season. There is not much pains taken with their cultivation, and they are seldom more than half the size of those reared with so much care in our own country, and not to be compared with them in flavour. They are too much inclined to become woody and tough, but even at their worst they always seem to be appreciated, and the coolies, who are their principal vendors, find a ready sale for them.

The Cape Gooseberry is a small shrub, and bears a bright yellow berry, as unlike a Gooseberry as one thing can be unlike another. It is a wild plant, and is found all about near Maritzburg. It is a useful little fruit, and good when cooked in various ways. The Amatungula is another wild berry that is a good deal sought after; it is bright red, and is used for preserves and jelly. The jelly is not a bad imitation of red Currant.

The Papaw is a large round fruit, that grows on the coast; it is chiefly useful for cooking purposes, and from its flavour and colour might very well pass for an Apple.

The Fig tree does well in Natal, and no doubt, if the birds would only allow the Figs to ripen, they would be very good; but though we had several large-sized trees in our garden, I cannot say that we ever had the satisfaction of eating a single Fig off them; the birds gobbled them all up when they were only half-grown.

Grapes answer very well against a wall. But let me warn anyone against trying to make them grow out in a field. Preparing the ground for them—for it must be properly prepared—is a great expense, and they do not do well at all. Some people have fancied that they might be cultivated in that way, as they are at Cape Town, but it is not possible, owing to the seasons in Natal and at the Cape being quite different. The rainy season comes just at the wrong time for Grapes in Natal. We tried the experiment, and fancied we were going to make a heap of money by it, but it proved a complete failure, and we gave our Vines every chance. We got several hundred plants of different kinds; and had a Swiss gardener, who professed to know his work, to look after them, but all to no purpose. The heavy rains came, and beat down some of our poor Vines, and washed others out of the ground, and the hot winds frizzled up the rest, very few of which escaped, and I do not think even those will ever bear any Grapes. And I should be afraid to say what, with the gardener's wages and Kaffir's labour, and the plants, our unlucky venture cost us. I asked an old experienced gardener about it, and he said he did not believe Grapes could ever be grown in Natal, without a good wall to support them. Then they do very well, grow to a large size, and are of fine flavour. But as houses are usually low, it is not so easy to get a good wall.

The Prickly Pear, the fruit of a Cactus, is watery, somewhat tasteless, but not unpleasant. It is extremely unpleasant to pick through, as it is covered all over with minute thorns, which get into one's hands. The only way to get at the Pears comfortably is to take a knife and fork and cut them off into a basket. The Cactus is almost a weed in the colony, and makes a very secure hedge, as cattle are afraid to jump through it on account of the prickles.

There are Peaches in great abundance, but they are not satisfactory. They suffer from the heavy rains which come in the summer, just when they ought to be ripening, and want most sun, so that they really have no chance, and they drop down or are blown off the trees in a green state, in which they are only fit for pigs. Some of the early white Peaches ripen, and are not bad, but the commoner yellow kinds seldom come to perfection, and Nectarines and Apricots fall from the same cause. I believe it is from Peaches that a spirit called Cape smoke is made, which I should think is only second to Natal rum in its injurious effects; but it is popular on account of its cheapness and intoxicating qualities.

Pomegranates are gorgeous in colour and pretty in form. I have seen a whole orchard of them, and they certainly made a splendid show. But I think their good qualities end with their handsome appearance; they are full of tasteless seeds, and have scarcely any juice.

Of all English fruits in Natal the Raspberry seems to succeed the best; it often surpasses ours at home. As much cannot be said of Strawberries. The heavy summer rains wash all the taste out of them, and beat them into the ground, so that in eating a Strawberry one is apt to swallow as much of one's mother earth as Strawberry.

Apples of a common, useful sort are plentiful; but I have never seen any very fine kinds grown in Natal, but I should think there is no reason against their doing well.

The Mulberry is a stunted sort of tree, with far smaller leaves and smaller fruit than that which we are accustomed to see in England; it is sweeter and not unlike our Blackberry, and is used for jam and tarts. I never heard of any Plum or Cherry being grown in the colony. I suppose the climate is unsuited to them. The Olive does well, and I am surprised it is not more cultivated, as it is profitable; I believe it is rather trying to the patience, as it is some years before an Olive bears, but when it does, it is a small fortune to its owner. A colonist in Natal has no excuse for being without a good kitchen garden. With the exception of a few drawbacks everything favours him. The soil is exceedingly productive in most parts, and there is generally plenty of means of irrigation; of course of the greatest importance in the dry winter weather. The first thing to be done is to make a good fence; and I have been told there is none equal to a hedge planted with Cactus or Aloes, and, if possible, a deep ditch on the wrong side. That seems the greatest protection against that plague of all gardeners, the oxen, which are allowed to roam about the veldt at will. Most English vegetables, as well as Potatoes, Peas, and French Beans, are equal to those at home; and if the matter of irrigation be accomplished—not difficult where there are so many streams at hand—anyone may have a succession of these vegetables all the year round. No homestead ought to be without a good garden. Industry alone is wanted, and I fear that is very much wanted in Natal; for good gardeners are few and far between. And in the whole of the town of Maritzburg there is only one greengrocer's shop, which of course cannot supply the demand, and exorbitant prices are asked for its mouldy little heap of Potatoes and flabby vegetables or fruits displayed in the dust-covered windows. Carrots also do well, and grow to a very respectable size; indeed, I have seen some not unworthy of our shows in England.

Turnips are apt to fall, and at their best are never quite satisfactory. Cabbages, Cauliflowers, and Spinach are excellent; of the latter there is a wild kind, just as pleasant as the cultivated sort.

Beetroot grows to perfection; but I cannot make out that that very useful root Mangold wurzel cannot be grown, though one would think it had very much the same nature as the Beetroot.

Cotton, Coffee, and even Tea, grow in Natal. I am not able to give any sufficiently exact information on the subject. Cotton does best on the coast, as it requires a good deal of warmth. Coffee also seems to prefer a tropical climate, though it will grow near Maritzburg. Tea does not seem to have been turned to much account; I have only seen a few bushes of it. I suppose there is some difficulty in its preparation, and therefore it is not cultivated to any extent.

American Hazel Nuts.—*Corylus americana*, or the American Hazel Nut, is very common in Western America, and, unlike the other species, seems to only thrive permanently in the open ground. It is said to be of a better flavour than the Filbert, and varies enough in size and quality to suggest the desirability of attempting its improvement. *C. rostrata*, the beaked Hazel Nut, is found generally in the Northern States, but extends down the Atlantic coast as far south, we believe, as the Carolinas. We do not know that it is found in the north-west. It is lower and stronger than our common Hazel bush, and has the "hulls" curiously twisted about the Nut, whence its name. It grows from 2 to 5 ft. in height.

A New Measuring Instrument.—The Boston correspondent of the "Academy" says:—"May I mention an ingenious instrument which I had the pleasure of seeing the other evening, and hearing explained by its inventor, Mr. Edward C. Pickering, Professor of Physics in the Massachusetts Institute of Technology? It is designed for measuring the distances and heights of mountains. It consists of a common telescope, with a level attached, a scale of equal parts in the eyepiece, and with a mirror of plate-glass fastened to the object, so that it can be set to any angle. Two images are seen, one through the glass, and the other by reflection from its surface, and any two objects may be made apparently to coincide by turning the mirror through the proper angle. Selecting as one object the mountain the distance of which is to be measured, and as the other any convenient, well-defined point, the telescope is moved through a known distance, and the apparent change of position of the two images is measured by the scale. From this the distance may be determined with all the accuracy needed for an ordinary map. It is, in fact, equivalent to the "stadia," with the advantage that an assistant

need not be sent up the mountain, for it can be measured with the same accuracy and precision as with a pole 100 ft. or 1000 ft. long. The altitude is then determined by levelling the telescope and reading the apparent elevation from the graduated scale which is now turned round. By a second inclined level, higher mountains may be measured. It will probably equal in accuracy a large theodolite, without the necessity of employing a finely graduated circle or delicate mounting. It is therefore inexpensive, light, and easily used. It could be carried by any traveller, and would give the height of a mountain much more accurately than a barometer. Further, a whole range of mountains might be measured in a few hours by this instrument, while with the barometer a single ascent often occupies several days."

Submergence of Trees.—In past ages the Yorkshire moors were covered with woods and forests equally with the Lancashire moors, as the remains of large trees have been frequently discovered on the moors. One such discovery was made during the last autumn on the hills lying to the north-west of the town of Holfirth, close to the well-known Ford Moor. The trees were found during the formation of the Upperthong Reservoir (at present in course of construction), which lies in a shallow depression between two long ridges of lower coal shales. The reservoir is dug out of a deposit of no great depth, which principally consists of clay and black boggy peat, both lying on coal-measure shales. The excavation, when we saw it, was about 200 yards long by 70 yards broad. This area contained the prostrate trunks and upright boles of about thirty large trees, which had had the black peat removed from them, but were otherwise undisturbed. Some of these trunks are 30 ft. long, and of good girth at the upper part, showing the age of the trees to be not less than half a century. The wood was black and soft, but perfectly sound at the heart. The trunks, which were clearly identified, were those of Oaks, Beeches, and Birches, the latter predominating. The course of events appeared to lead to a conclusion somewhat like this:—At one time, in past ages, on the hills about Harden Moss, clumps of large Oaks, Beeches, and Birches grew in vigorous health. Suddenly, by some catastrophe, the trees were broken off near their roots, and fell prostrate where they are now found. The drainage from Harden Moss soon after was stopped and converted the place into a swampy bog. Peat was then formed and enveloped the trees, and the whole became hard and dry. After a time a small lake was formed over the peat. The water from higher ground bore fine clay and marl, and spread it over the peat to a depth of about 3 ft. Then the lake drained off, and the marshy turf grew on the clay which now forms the surface soil, an aspect being given to the shallow depression which appears to have existed from the earliest historical times.—J. PLANT.

Canna liliflora.—In a late number (Nov. 1) of the "Revue Horticole" the Comte de Lambertye has given some interesting details respecting the culture of this *Canna*, which has become rare in collections. He has succeeded in keeping it since 1860, alternately in a temperate house in winter and in the open air in summer—from the end of May till the first week in October; and it has flowered and produced seeds year after year without any special care or treatment. The largest specimens in the possession of the Comte de Lambertye, at Chaltrait, gave the following measurements on the 27th September last:—Height from the soil to the tips of the upper leaves, about 17 feet; circumference of the clump near the ground, about 8 feet; circumference near the top, about 20 feet; number of stems, thirty; girth of one of the largest stems near the base, about 10 inches; length of the longest leaves, 3 feet 9 inches; width of the largest leaves, 20 inches. This plant flowered in June, and at the end of July it had ripened seed in abundance.

A Beautiful Country.—Bosnia is so little frequented by tourists, and so little known, that a few words about the aspect of the country and the nature of its soil may not be out of place. A few extracts from one of a series of letters addressed by the Superior of the Trappist convent near Banjaluka to a brother Trappist in the Tyrol will give some ideas on the subject. "People outside Bosnia hardly have a notion how beautiful a country it is. True, the banks of the Rhine from Bingen to Cologne, the shores of the Swiss lakes, of the Lago Maggiore, and the Lago di Como, are very fine, but if you take away from them all that has been done by the hand of man—the castles, ruins, villas, villages, towns, and vineyards—you will find that Nature undorned has not done so much in those spots as she has for Bosnia at Ialca and Iulisar. True, again, that the views of Constantinople and Naples are magnificent; but the work of man, prolonged through ages, has its share in the beauty of those views. For my part, ever since I was a boy I have travelled all over Europe in search of beautiful scenery, but I have never found Nature in itself, without the help of man's works, so exquisite as at the Lake of Iegero and at the Ialca cataracts—far superior to

the fall of the Rhine at Schaffhausen. In two words, Bosnia is like Styria or the Tyrol, only more beautiful, with grazing lands more extensive, and with a climate which allows the cultivation of almost any European produce high up on the mountain-side. There is abundance of mineral produce, which only waits for the miner; river streams on every side offer extensive water-power almost everywhere; the forests abound with costly trees. Ignorance and mismanagement alone could have allowed such riches to lie waste for so long. We (Trappists) are, I am happy to say, teaching the inhabitants little by little to realise what they possess."—"Times."

Origin and Extent of Cranberry Culture.—The future historian of Cranberry culture will revel in a richness of synonyms. On Cape Cod the grounds planted with this fruit are called yards; in the interior of Massachusetts and in Rhode Island, meadows; in Wisconsin, marshes. New Jersey men speak of Cranberry bogs and plantations. The Cranberry grows naturally on swampy lands. Its first known culture was at Dennis, on Cape Cod, about sixty years ago. Captain Henry Hall had the fruit growing wild about the margin of a pond, and to increase the fruit-bearing area, he shoveled sand from the banks into the edge of the water. The runners promptly overspread the new soil. When the shovel would not suffice, the wheelbarrow came into play, so by degrees the entire pond was filled up, and covered by runners from the marginal plants, thus constituting the first sanded Cranberry bog. It is still in good bearing. In round numbers, I think the area under Cranberry culture in New Jersey at the present time is 5000 acres; New England and New York—judging from their crops—aggregate about the same acreage. Wisconsin, Minnesota, Indiana, and Michigan, probably have 5000 acres in Cranberry plants, either partially or wholly cultivated—in all about 15,000 acres!—N. R. FRENCH.

Varieties of Tea.—Tea is a kind of Camellia, and very like a miniature copy of that well-known ornament of our greenhouses and conservatories. Then I was told the distinction between the Chinese plant and its taller relative, which is wild in Assam. Then I learned the difference between black tea and green. Both come from the same plant, but the former is fermented and the latter is unfermented. I asked about the half-fabulous teas one has heard of, which never come into the market, "tea of the Wells of the Dragon," for instance. Such things, I was told, if ever made, would be the young unexpanded leaf plucked and prepared separately. Then I asked about Flowery Pekoe, which, in my ignorance, I supposed to contain portions of the flower. Flowery Pekoe, I was told, is the very finest kind of black tea, and has its name from the soft down of the young unexpanded leaf which may be perceived upon it. A little of it is sometimes prepared separately. Orange Pekoe, which is much the same, has its name from the colour of the unexpanded leaf when dried. Its orange colour enables it to be easily distinguished and picked out. You must understand that save and except the half-mythological teas I have alluded to, all black tea, from Orange Pekoe down through Pekoe and Souchong to Bohea, which last is made of the largest and oldest leaves, and all green tea, from Young Hyson down to Hysonskin, are plucked and prepared together. The sorting is an after process, done partly by sieve, partly by hand.—GRANT DUFF.

The Fever Gum Tree in the Roman Campagna.—In a paper read before the Pharmaceutical Society the other evening, some interesting facts relating to the influence of the Eucalyptus globulus, or Australian blue Gum tree, in a malarious district, were communicated by Mr. R. G. Glover, as having come under his observation during a recent stay in Italy. The locality chosen for the experiment was the most desolate part of the Campagna, about three miles from Rome, where tradition fixes the place of the execution of St. Paul. On that spot three magnificent churches and a monastery were erected, but towards the end of the last century they had to be abandoned by the fever-stricken monks, and the ruins had since become a show-place for visitors in the winter. About six years ago some French Trappist monks, under the superintendence of Padre Gildas and Fra Orsi, planted Eucalyptus trees in the cloisters, and they have already grown to a height of over 30 ft. During the first four years the monks did not venture to live on the spot altogether, but returned to the city to sleep every night during the summer and autumn months. For the last two years, however, all the monks have inhabited the hitherto fatal spot, the community sleeping in the monastery, and remaining day and night all the year in the most fever-stricken spot of the whole Campagna. Notwithstanding this, the monks, most of them beyond the prime of life, have existed and preserved their health. Whether this result has been due to the direct influence of the trees upon the atmosphere or the soil, or to the efficacy of a kind of liqueur which the monks prepare from the Eucalyptus and take with their cup of black coffee every morning, Mr. Glover leaves others to decide; but he is of opinion that, if the

Italian Government were to turn its attention to the subject, the whole of the desolate plain might be restored to the condition in which it unquestionably was in the days of the Roman Empire.

A Step in the Right Direction.—I see, by an advertisement in THE GARDEN, that the Wimbledon Society of Gardeners have obtained leave to meet at the Lecture Hall once a fortnight, to discuss matters relating to horticulture. This is as it should be, and puts me in mind of the days of yore when we used to meet to discuss the merits of the Pink, Auricula, Carnation, and similar florist's flowers; few at the present day are aware of the benefits derived from such meetings. If amateur cultivators would, in their respective neighbourhoods, contrive to get together such meetings, which involve no expense, they would probably learn more about matters pertaining to gardening in a year than they would otherwise in seven. Societies might be formed with no other object in view than that of periodical conversations and discussions among their members, and the interest of such conversations and discussions might be increased by the production of any plants, flowers, fruits, or vegetables that any member might have in his possession in a state fit for showing. By having the subscription to such societies on the lowest possible scale many would be able to join them, and much good would be the result.—EDWD. BENNETT, *Rabley, Herts.*

Sources of Medicinal Rhubarbs.—At the garden of the Royal Botanic Society, Regent's Park, a plant of the *Rheum officinale* has borne ripe fruit. This plant, a native of Thibet, is the species shown by Baillon to be the source of some at least of the "Turkey" Rhubarb of commerce (see *J. Bot.*, 1872, p. 379), and has been figured in the "Botanical Magazine" for last December (t. 6135). It is an exceedingly handsome plant when in flower, and certainly not less so in fruit. The broad wings of the triangular nuts are of a brilliantly bright red, and cordate at the base and apex, the whole fruit being nearly half an inch long, and pendulous in clusters. They are very indifferently rendered both in form and colour in the Bot. Mag. plate. Quite recently Professor Maximowicz has proved that the Rhubarb which enters Siberia by Kiachta, or "Moscow" Rhubarb, is yielded by *Rheum palmatum*, Linn., which was found in 1872-3 by Przewalski, on hills at Tangut, in the province of Kansu, in North-west China. This is a re-discovery, for the species was originally brought to Russia in 1750, and thence distributed to the gardens of Europe, as the number and source of officinal Rhubarb. There is no necessary antagonism between the statements of Baillon and Maximowicz, and it may well be that the drug is afforded by both species of *Rheum*.—"Journal of Botany."

NOTES AND QUESTIONS—VARIOUS.

Weymouth Pine in Wiltshire.—In the old Fir woods on this estate there are several groups of this Pine, some of the largest specimens of which measure from 80 to 90 ft. in height, and from 6 to 8 ft. in circumference of stem at 5 ft. above the ground. In this country it is inferior as a timber tree to the common Spruce and Scotch Fir.—G. B., *Longleat.*

Cockroaches and Crickets.—After repeated trials of different substances for the destruction of these, I find James's Phosphoric Paste to be the best, inasmuch as it clears them off the first night. I place two or three pieces of it, about the size of a Hazel-nut, on bits of paper, and lay it about in dry places. This paste is rather expensive and somewhat difficult to obtain.—R. H. B.

Prizes for Roses.—At the annual meeting of the Frome Rose Club, which took place the other day, it was resolved to considerably increase the amount usually given in the shape of Prizes for Roses. At the Crystal Palace £115 is given in prizes for Roses; at Oxford, £107; at the Royal Albert Hall £160s.; at Birmingham, £144; and it was thought that the Frome Club ought to give £100.

Celosia pyramidalis var. *Reid's Perfection*.—Mr. Thompson, of Ipswich, (see p. 80), describes this as attaining a height of 2½ ft., but that is a mistake, inasmuch as it attains a height of from 4 to 5 ft., and has a diameter of from 2½ to 3 ft. Mr. Thompson's description is otherwise perfectly correct. We grow a large number of plants of this last year; they formed a line on each side of a house 140 ft. in length, and were really magnificent, the brilliancy of their colours being perfectly dazzling.—REID & Co., *Appley Bridge, Wigan.*

Dressing for Vermin-infested Soil.—Quicklime and soot, pointed into the ground at sowing time, half a bushel to each per 30 square yards, is a good preventive; but a better remedy is gas lime, at the rate of half-a-peck per rod, or twenty bushels per acre. The ammoniacal liquor of the gas-works, diluted with six times its volume of water, and applied to the ground with a rosed watering-pot a day previous to sowing, is also a good preventive of canker.

Hybridising Bouvardias.—Will "R. H. B.," who writes so well on Bouvardias (see p. 121) state whether *B. leiantha* bears male and female flowers on the same plant or not, as I have some recollection of having read (see "Social Science Review," 1872, art. "Bud variation") that it is dioecious? It may interest some to know that M. Lemoine, of Nancy, this year announces a new hybrid obtained by fertilising *B. jasminiflora* with pollen obtained from *B. flava*. It is described as having the umbels of the former, and the seed-parent, while the flowers are of a clear canary-yellow, and sweet-scented.—B.

Macqaya bella.—Will some correspondent kindly give me a few hints on the cultivation of the above plant? With me it grows freely in the stove or in the greenhouse, but never flowers in either.—W. W.

An Old Time Notion.—There is a popular belief here that timber cut down in the forest before full moon is sure to decay quickly. This belief extends also to the picking of fruits from trees before that time. Is there any ground for this belief?—PRESTON POWERS, *Florence.*

[Vol. IX.]

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

GESNERAS FOR THE GREENHOUSE IN WINTER.

GESNERAS, though classed among stove plants, are found to be admirably suited for the winter decoration of the greenhouse, provided care be taken not to place them in draughts of cold or dry air. In a temperature ranging from 45° to 50° as a minimum, Gesneras will continue to put forth a succession of flowers, which will last much longer than if exposed to a higher temperature. The moist atmosphere and subdued light of winter suit their development, and though they may be grown for summer use, indeed, for any season of the year, they are in reality winter-blooming plants. There are many species and varieties of them well worthy of cultivation; we have tried several, and among the rest the old shrubby *G. clongata*, which is now very showy; but the kinds at present under notice will consist of herbaceous bulbous-rooted sorts. Of these the best are *G. Cooperii*, an improved variety of *G. zebrina*, and *G. cinnabarina*. These are indispensable to the conservatory, and should be grown in quantity wherever plants for table decoration are in demand. Even after they have ceased blooming, if the foliage has been preserved in health, they have beauty sufficient to cause them to be retained in the show house as decorative plants; for, besides being flowering plants of the first order, they are also fine-foliaged plants. *G. zebrina splendissima* is a very robust grower, forming massive stout stems and foliage, which, when well developed, is broad and flat, showing the serratures prominently round the margin of the leaf; the colour is glossy velvety-red, with the light green colour showing through in numerous spots and patches. No foliage is more liable to injury from indifferent culture than that of the Gesnera; it quickly becomes spotted from rain or sunshine, curls inwards at the edges if it is grown in too dry an atmosphere, and loses the delicate glossy texture of the hairy surface. Gesneras are nevertheless of very easy culture, with a little intelligent care in furnishing them with these few requirements. *G. Cooperii* is also a very robust grower, dwarfier than the last, shorter-jointed and of a closer habit, the foliage broad and massive, and of a pale green colour, with numerous marbled spots of a lighter tint. As a flowering plant it is perhaps to be preferred to the last, as the foliage has the effect of showing up the colour of the flowers to great advantage. The gem of this genus is, without doubt, *G. cinnabarina*, not so robust in growth as the two last-named, still with a vigorous and free constitution, dwarf and short-jointed in habit; its great attraction is the brilliant velvety-red colour of the minute hairs on the foliage; the flowers, of a delicate orange-scarlet, are produced in profusion, and from four to six weeks in succession. *G. exoniensis* is a desirable variety, intermediate between *zebrina* and *cinnabarina* in habit, but much in the way of the last. *G. velutina* is also a dwarf variety, robust in habit, after the style of *exoniensis*, with its flowers of a pink colour. All Gesneras require about the same culture, and at the present time it will be necessary to preserve the foliage in health as long as possible, so as to mature the growth of the bulbs. The plants should be placed in a warm pit on a moist bottom, such as tan or leaves, and moderately watered until the foliage shows signs of decay, when water may be withheld altogether; some weeks will elapse before the plants become thoroughly dry. The pots, with the soil and bulbs, should then be stored in a shed or cellar where they will not be subjected to damp or too low a temperature, say, below 50°, for a low temperature with damp is fatal to most stove bulbs at rest. This plan is preferable to removing the bulbs from the soil and storing them in sand, besides being more natural. They may remain in the pots until they are started again into growth for the winter; to save room the pots may be piled in tiers, from which no injury will ensue. About the second week in July is a good time to start the bulbs, when they must be cleared of the old soil, and, to save

space at the time, they may be placed thickly on a thin stratum of soil and covered over with the same in shallow boxes or pans and placed in heat to start; the stock can readily be increased by breaking the bulbs into two or three pieces instead of planting them singly; each piece is sure to push into growth. In a few weeks they will make their way through the soil, and, when they have made a little bunch of young roots, they should be taken from the boxes and potted, some singly into 4-in. pots, some in threes into 6-in. pots, according to the purpose for which they are intended; both sizes must ultimately be shifted into two sizes larger. To make a very large specimen six or more plants may be placed in shallow pans after the manner of *Achimenes*, but those grown in the smaller sizes are best, and, in fact, a very considerable specimen can be grown in an 8-in. pot; for single plants a 6-in. pot is sufficiently large, and looks better than when three or more are grown together. The soil that is generally recommended for Gesneras is an open fibrous material, enriched with decomposed horse-manure or leaf-mould; a thoroughly good fibrous peat for the staple of the soil is best, but a very fibrous light loam, with a little sand, will be found to answer as well. The pots should be carefully drained to a fourth of their depth, and when they have got well filled with roots, a regular system of watering with weak liquid manure should be commenced, taking particular care not to allow a single drop to fall on the foliage; this must specially be attended to if the plants be grown in lean-to pits and under the hand in watering; neither should the syringe ever be used overhead among Gesneras, the delicate covering of minute coloured hairs being so susceptible to injury from foreign matter in the water. The chief consideration as regards the successful culture of Gesneras is the choice of a proper place in which to grow them, so that they may enjoy the atmospheric conditions necessary to their proper development. A low lean-to pit will suit them well, in the absence of a house of larger dimensions; fire-heat is not necessary until the end of October, in fact, may be prejudicial to them if abundant moisture be not present; still, a cold pit will not suit them well, being subject to sudden changes of temperature and consequently of moisture. A pit in which early Melons have been grown on a bed of fermenting leaves, which still continues to yield a mild bottom-heat and to emit a warm moisture into the atmosphere, is just the place for them, or a half-spent tan-bed answers just as well; spread a few inches of coal ashes, or saw-dust, over the leaves or tan, on which set the pots, and keep this surface moist with the rose of a small watering pot. The lights must be shaded with canvas during bright sunshine, or a permanent shading of whitewash will answer perfectly up to October, sunshine and a dry atmosphere very quickly causing the foliage to spot and curl inwards at the edges. By the middle of October the lights should be cleared of the whitewash, and if bright weather ensue some lighter shading may be used. At no time is much ventilation required, and that only at the top of the lights. All Gesneras may be started at one time and grown on together until October. It is easy to push a quantity forward into bloom by Christmas by giving them a little extra heat in a light house; some move the plants into low span-houses in winter. Of course, fire-heat is necessary from October onwards to maintain a minimum of 50° until they have come well into bloom. Our first lot, composed entirely of *G. zebrina*, accompanied the early *Poinsettia* in December; *G. Cooperii* followed, and now *cinnabarina* and others are fast coming into bloom, and will continue for more than a month. Gesneras are readily increased by using strong leaves with the ribs cut in various places, pegged down on sand, and kept in a moist heat, when they will make little bulbs at every incision; whole leaves inserted by a short piece of the stalk in sand make the strongest bulbs, a single leaf in a 3-in. pot being the best mode. These cuttings should be made in summer, when growth is vigorous, and a close moist compartment in a pit should be devoted to them; a hand-light within a pit answers well when a quantity is to be raised, otherwise cloches can be used. Gesneras will be found to be as indispensable as *Poinsettias* for winter decoration; they stand the temperature of an ordinary greenhouse or conservatory better than the *Poinsettia*, and, on the whole, are more useful for table decoration.

W. D. C.

NOTES OF THE WEEK.

— IN Mr. Hibberd's lecture on fruit culture, at the Society of Arts, there is a mistake which deserves to be pointed out, as it is published in various journals. He says:—"The various methods of pruning practised on the Continent have not in any marked degree obtained a settlement in this country, and there are two powerful impediments to the establishment here of what are especially known as French methods of pruning fruit trees. In the first place, our climate is unfavourable, because a tree several times pinched requires a long, bright, dry autumn to ripen its late-formed wood, and of that the Frenchman is fairly assured, while the Englishman is not." Now, here it is plainly seen that the writer supposes the French pinch their trees "several times," but this is not the case. The practice Mr. Hibberd refers to is English, and we have never seen an instance in which it was practised in a French garden. The French are not such novices in fruit culture as to pinch the shoots of their fruit trees several times, and thus start the young fruit-buds at the base of the current year's wood into soft woody growths, and thereby do irreparable mischief. Nor is the close pinching at three leaves, of which we have all heard, ever practised in France, in any system of pruning for fruit that we have ever seen or heard of.

— SIR ANTHON GUINNESS has made the Commissioners of Stephen's Green, Dublin, a free gift of £5000, to enable them to pay off their debts and convert the green into a public garden.

— MR. MURRAY has just issued the second edition of Mr. Darwin's "Animals and Plants under Domestication," a book of the highest interest for horticulturists as well as for the general reader.

— Two writers in the "Revue Horticole" contend that the common practice of watering stove and greenhouse plants with tepid water is wrong. They consider they actually get a much better result by using the coldest water within reach.

— SAXIFERAGA BURSERIANA is, among early and Alpine flowers, the gem of the week. In habit it resembles a miniature Juniper Saxifrage, with a beautiful large white flower, out of all proportion to the diminutive plant that bears it.

— THERE will be a national Horticultural Exhibition at Rome from May 6 to 14, the first of its kind, as stated in the "Bulletin" of the Royal Tuscan Horticultural Society, that has taken place in that city. There is also to be a great Horticultural Exhibition in Vienna from April 29 to May 4.

— AN ACRE AND A HALF of ground will be set aside as a garden of the indigenous flowers and plants of Japan at the American Centennial Exhibition. This to horticulturists should prove a very interesting feature, if so formed as to fairly represent Japanese vegetation.

— M. CARRIERE speaks very highly of a variety of the Japan Privet called *Ligustrum japonicum robustum*. He says that it is hardier and altogether stouter than the ordinary Japan Privet; and if this be so, it should prove a very desirable late-flowering shrub, or rather low tree, for the ordinary kind becomes a low tree in favoured spots.

— THE KING OF THE BELGIANS is erecting at Laeken a grand winter garden close to the palace. It is covered with a roof about 120 ft. in height, so constructed as to need no support in the centre. Tall trees will thus have room for full development. The cost of the building is estimated at 2,000,000 fr. (£80,000).

— ONE of the most effective among white-flowered Orchids is *Cyclopogon cristata*, a native of Northern India. Of this, a fine specimen is now in bloom in Mr. B. S. Williams' collection at Holway. It measures upwards of a yard in diameter, and is altogether a strikingly handsome plant. A Manchester correspondent states that he has a specimen of this Orchid now bearing nine flowers on a spike, a number rarely, if ever equalled.

— THE great success of the International Potato Show held last year has led the promoters to arrange for a similar exhibition in the autumn of the present year. Arrangements have therefore been made for a second great Potato Show, to be held in the Alexandra Palace, on September 23th and 29th next. The prizes will amount to over £100, and the subscriptions are headed by one of forty guineas from the Alexandra Palace Company.

— THE stately and graceful Palm, *Scaevortia elegans*, is now in flower in the Royal Botanic Gardens at Glasnevin, Dublin. The specimen is a noble one, and the inflorescence bursts from the lofty stem about midway. *Brownia grandiflora* has been for some time in flower in the large stove at Glasnevin, and the noble tree, for such it is, of *B. grandiceps*, in the same house, is just now showing flower, and a magnificent display may be confidently looked for by-and-bye. These *Brownias* are of remarkable beauty, and deserve to be seen more frequently in our botanic gardens and large private collections.

THE INDOOR GARDEN.

COOL TREATMENT FOR FERNS.

MANY so-called stove Ferns may be successfully cultivated in a greenhouse where the temperature from fire-heat alone never rises above 45°, and is often below 40°. Many years ago I was acquainted with a lady who was specially interested in the culture of Ferns. She grew them in a lean-to greenhouse, with the usual kind of stair-like stage, and a shelf all round the front and ends. In this house were many pretty little specimens of such kinds as the Bird's-nest Fern (*Asplenium Nidus Avis*), many varieties of *Adiantum*, several *Gymnogrammas*, *Platycerium alcicornis*, *Pteris tricolor*, and others. She admitted that with certain kinds she had some trouble before she could induce them to take kindly to her cool system of treatment. This was, in most instances, due to her buying small plants, and having no house of intermediate temperature in which to grow them for a little time after receiving them, so as gradually to acclimatize them, if I may use the term. Failure, however, usually teaches more than success, and she soon discovered that by making her purchases in August, and by buying only such plants as were thoroughly established, and in the case of any scarce kind, waiting patiently until it became plentiful, so that a good plant that had not been over-excited by forcing might be obtained, she seldom lost even a single plant. As regards treatment, they were seldom or never shaded; in sunny weather moisture was plentifully sprinkled about the stages and walls, but not much over the plants, and a free circulation of air was kept up on all favourable opportunities. All potting was done early in summer, so that the pots might be full of roots before the short days came. In winter much less water was given than in summer, but they were in no sense dried off, and of course the atmosphere was kept comparatively dry. Anyone who has anything to do with furnishing knows that the cooler plants are grown, if healthy, the better they are adapted for the purpose and the less they suffer; a remark that holds good in the case of Ferns, that may be required to be grown in a lower temperature than that to which they are usually subjected. They may, it is true, in some slight degree, lose that exuberance of growth which plants in a higher temperature may possess, and the fronds may be paler in colour; but, on the other hand, they may be moved anywhere whenever the temperature is above freezing, and may be inspected without having to endure the steaming tropical heat of a stove. Many, indeed, of our most beautiful Ferns will flourish in a comparatively low temperature; but of course plants that have been growing in warm houses must be gradually enured to a lower temperature, and, as a matter of course, less moisture will be required, and when potting—especially at first until some experience has been gained—smaller shifts should be given than under ordinary circumstances, and all potting should be done not later than June. These remarks apply not only to pot plants set on stages, but also to naturally-arranged Ferneries, in which the pots are plunged out of sight, or where the plants are grown without pots.

E. HOBBAY.

Or Phalœnopsis, which may be ranked amongst the most beautiful of all winter-flowering Orchids, 300 or 400 are now in full flower in Messrs. Low's nursery at Clapton. Among these we may specially allude to the new and beautiful *P. casta* and *P. leucorrhoda*, and also to some distinct and richly-coloured forms of the better known *P. Schilleriana*, to say nothing of *P. amabilis* and *P. rosea*. These plants are growing in a span-roofed house about 60 ft. in length, to which air is freely admitted over the pipes in mild weather, and moisture at the root is liberally administered. Thus treated it is difficult to imagine a more beautiful sight than that presented by healthy and free-blooming plants like those to which we allude. Other Orchids in this collection are in the best possible health and vigour, *Dendrobis*, *Laelias*, and *Saccolabiums* luxuriating under the same treatment. Several plants of *Dendrobium Wardianum* are blooming freely, and we noticed a very brilliantly-coloured variety of *D. crassinode*, named *Barberi*, the tips of the ivory-white segments being of the most vivid magenta-purple possible. We may add that the rare and beautiful *Phalœnopsis intermedia*, *Portei* is now blooming freely in Lord Lonsborough's collection at Surbiton.

POTTING AND PLANTING.

It would be hardly possible to over-estimate the importance of these two operations. It is, in fact, almost useless to study the requirements of the many varied forms of vegetable life in respect to light, air, moisture, &c., if the conditions necessary to a healthy and vigorous root-action do not receive due consideration. The advantage of a good start in life to a young plant is fully recognised by practical men. A Vine or fruit tree, for instance, will generally indicate by its first year's growth the degree of perfection at which it may eventually arrive. In the case of soft-wooded, quick-growing plants, the effects of judicious management in this respect will manifest themselves even more strikingly. That which retards or diminishes growth in any way, must necessarily detract from the general health and vigour, and affect the future welfare and progress of the subject. It is, therefore, evident that too much care can hardly be bestowed upon all operations by which the action of the root is affected. The skilful, intelligent cultivator endeavours to preserve his plants from checks of all descriptions. He guards against extreme vicissitudes of temperature, moisture, &c., and he knows full well the vital importance of preserving in their normal state of health those organs which draw from the soil the requisite daily amount of nutriment. If the root receive an injury, the whole plant immediately feels it, and suffers in proportion to the damage inflicted. Notwithstanding, however, that these few facts are well known to, and acknowledged by, the gardening world in general, there still remains a lack of due appreciation of their importance, as is often evidenced by the want of care and reflection exercised in the details of planting and potting. A few well-grown subjects reflect more credit on the possessor than a large collection of badly-managed ones. Whether plants be grown for pleasure or profit, for the production of bloom or fruit, the effects of strict attention to a few details, which the inexperienced might regard as unimportant, will be amply rewarded. That which induces a great deal of this work to be performed in a hasty, haphazard manner, is the fact of employers oftentimes being too apt to judge of the skill and application of the workman by the amount of work got through in a day. In this respect, there is, of course, a vast amount of difference between men. Some will always excel not only in quickness of manipulation, but, at the same time, will exhibit a greater amount of care in their operations than others. There are, however, few who can combine great speed with perfection of workmanship: and, as a rule, young men should not be encouraged to aim at arriving at this point, as it is calculated to induce a hasty, superficial manner of getting through their work. In removing a tree, or re-potting a plant, we are in a manner constrained to violate the laws of Nature—we mutilate the root and check its powers for a time; but the ill-effects which, more or less, this derangement causes, may be reduced to a minimum by adopting proper precautions.

The condition and quality of the soil used must, of necessity, hold the first place in our consideration; it is, however, rather to its preparation than to its innate qualities that I would direct attention. To the cultivator the soil-yard may be said to form the basis of nearly all his proceedings; and no pains should be spared to keep up a supply of the several kinds of mould that may be considered necessary, a portion of which should always be in a fit condition for immediate use. It is not always easy to obtain the exact kinds of soil that one would like—locality and various other circumstances often influencing the supply; but, with a little management, we may always contrive to render ourselves tolerably independent in this respect. I was once placed in peculiarly unfavourable circumstances in regard to the necessary compost; I could not procure a particle of good loam, the peat was of the most wretched description, and white sand was unknown. There was, however, an immense accumulation of very old leaf-mould and manure; the collection of plants was varied, but I had fair success with them, which I attribute to having every particle of soil thoroughly dried and exposed to frost before using it. Palms, stove plants in general, and many Ferns, grew admirably in it; in fact, the free root-action and corresponding luxuriant growth of many plants, for which I had always considered the best fibry

peat and silver sand indispensable adjuncts, quite surprised me: Gloxinias and Achimenes succeeded remarkably well thus treated. I may here just observe that the best-cultivated collection of Gloxinias I ever saw was potted in thoroughly decomposed manure with no other admixture. I would, therefore suggest that all soils should have careful preparation for use, more, I believe, depending upon this than upon the richness or natural suitability of the earth itself. Leaf-mould should be several years old—in fact, the older the better; and manure should never be employed unless three or four years old, and it should be well turned over as often as convenient during that time—every portion being exposed to sun, air, and frost—a strict observance of this injunction being absolutely necessary. When fit for use, it should be reduced to, and undistinguishable from, mould itself. There is, in my opinion, no greater evil than using manure in a lumpy state for potting, especially in conjunction with raw, unctuous loam. Great care must be exercised in watering, or the fibre is apt to perish, and the soil become sour, when all mechanical assistance is lost. Loam should be stacked some considerable time before being used; it cannot, of course, be turned about as in the case of leaf-mould, &c., but a portion should be well chopped and undergo a purifying process; if required in a rough state, each lump should be subjected to the sweetening action of the atmosphere. Peat should receive a similar preparation. A portion of each kind of soil employed for potting should always be kept under cover with the view of having it in good condition for use at all times when required, also that its temperature should correspond in some measure with that of the soil in which the plants are growing.

Advantage is often taken of rainy days to get through the potting work, and nothing is wiser than the employment of soil in a wet, sodden state. Mould for potting should be employed in a moist, but not wet, condition; if, on compressing a handful, it does not open again freely in the hand, it is too wet; at the same time it should contain enough moisture to obviate the necessity for immediate watering. Fibres seem to be produced more readily when the earth is in a semi-moist state. If one can, in the case of newly-shifted plants, dispense with the watering-pot for twenty-four to forty-eight hours, the displaced rootlets will, in that time, strike afresh into the new soil; or oftentimes a fresh lot of young roots will, in that short space of time, be produced. The use of dry soil necessitates a heavy watering; the check and excess of moisture often cause the delicate spongioles of the fibres to decay, and a certain period must elapse before these can be replaced; the plant in the meantime suffers, or, at the least, receives such a check that it takes some time to recover. If the pots and drainage be quite dry, they should be sprinkled; in the case of new pots, it is advisable to soak them before they are drained. The inside of the pots and the crocks should be of the same degree of moisture as the compost to be used, otherwise the lower portion of the soil becomes so dry that heavy waterings are needful to moisten it properly throughout; at the same time, the interior of the pots should never be in a wet sloppy state when used, as this will cause portions of the mould to adhere to the sides, and in the next shift much valuable root will be torn away. For this reason, too, it is indispensable that all old mould should be cleared from the insides of the pots. Nothing should be shifted or planted with the ball in a dry state. Plants intended to be shifted should be well soaked some time beforehand—if in the winter time, some twelve hours before being operated on; but in dry summer weather, two or three hours will suffice to drain away the superfluous moisture. In the case of a plant that may have become pot-bound, or in any way hard in the ball, it is advisable to pierce the same with a sharp skewer, and, in placing it in the fresh pot, to allow the soil to slope a little from the edge towards the stem, forming a kind of basin around it; the water will then go where it is most required. This will also apply to planting out-of-doors, especially in the case of shrubs grown in peat, which are often lost in the moving, through the water not being able to permeate the old soil. In potting off cuttings of all descriptions, the roots should never be in a dry state when placed in the fresh soil. In planting in the open ground, much time and labour may be economised by a little

extra care in this matter; transplanting may be done as well in hot weather as at any other time, and in the case of many plants, with greater assurance of success—as, for instance, in that of the *Magnolia grandiflora*.

Strong seedlings or cuttings that have to be transplanted in dry weather should be watered twelve hours before being moved; if then carefully taken up and immediately placed where the air cannot dry the roots, they will immediately lay hold of the ground, and one gentle watering will generally be sufficient to ensure their growth. I have found nothing better for transporting young plants in, when at this work, than a common pail; it is impervious to the external atmosphere, and, if covered with a damp cloth, will preserve them fresh for hours. This is a great advantage, as a sudden call may be often made upon men, necessitating their absence for some time. At the potting bench, it is a common custom to knock out a number of plants for cuttings at once, allowing them to remain some time fully exposed to a drying atmosphere. This is a very injurious practice, and if those who indulge in it were to study vegetable physiology even to a small extent, they would become alive to the baneful effects of this custom. Cuttings should never be allowed to become pot-bound; the stunted growth and the loss of roots which the forcible separation of the plants occasions, render them liable to the attacks of many insect enemies. The miserable, starved appearance which many soft-wooded plants assume when bedded out, may often have its origin traced to the want of timely potting off, and also to careless handling at the potting-bench.

JOHN CORNHILL.

Bayfleet, Surrey.

Toughened Glass for Greenhouses.—Is the glass, which I saw mentioned in THE GARDEN some time ago as capable of withstanding considerable shocks without breaking, yet introduced for sale, and, if so, at what prices compared with those of common glass? At what prices could I get in London, ready packed, sheets of glass 14 in. by 22 in., and 14½ in. by 16½ in., the thickness being what is usually called here "half double" (about 3.32nds of an in.). I refer to sheets of common greenhouse glass.—PRESTON POWERS, Florence. [The glass to which Mr. Powers refers has not yet been introduced for glazing purposes, and we do not think it likely that it ever will be. In the first place, it cannot be cut without considerable difficulty, therefore every square of the different sizes required would have to be cast separately. Ordinary 15 oz. sheet-glass may be procured at any respectable glass warehouse in London, cut to size at 3d. per foot. There is a great difference between this and the glass advertised to be sold in sizes, the latter being cut from the residue, or waste, from the sheets, and the sashes require to be made to fit such glass; while, in the former case, the glass is cut to order for glazing purposes.—I. W.]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Root Climbers.—When these are planted out under slats or stone stages, it should be borne in mind that they require as much moisture in winter as in summer, especially as hot pipes are frequently in close contact with their roots.—J. G.

Acacias shedding their Bloom-buds.—I have six seedlings of *Acacia* *opanthia* in pots, about six years old, and full of bloom-buds, which fall off every year about this time. What is the cause of this disaster?—B. B. [It is impossible for any one who has not seen the plants, and who knows nothing of their condition, to give a useful answer to such a question as this. It is, however, of course, owing to bad cultivation or neglect of some of the conditions necessary to the health of the plants.]

Hyacinths for Forcing.—In reference to "Chef's" remarks (see p. 150), allow me to say that early in January last I saw at Mr. Bailey's, Feltham, a fine collection of White Hyacinths, consisting of, I think, *La Boule de Neige*, a double kind equal in size of spike and general development to the best single varieties; and Mr. Bailey specially pointed out that owing to the massiveness and purity of the bells, they were most valuable for wiring and working in that form into bouquets.—A. D.

—"Chef" (p. 150) is right in the main in recommending only single Hyacinths for early forcing; but he should make an exception in favour of the double white *La Tour d'Auvergne*, a kind which produces a fine spike and one which will force better than any, even of the single whites. I always grow it for first cutting and have it in perfection at Christmas and even before that.—HENRY A. WIGNON, *Wilton Lodge, Mitcham*.

Single White Camellias.—Can anyone inform me whether or not this beautiful old variety is now in cultivation? In the "Magazine of Gardening and Botany" (1836 p. 150), the flowers are described as pure white, and like those of the single red in shape. It is useful as a seed-producer or for crossing other kinds; some are of opinion that it was imported from China, but Messrs. Chandler & Booth believe that it was raised in the Tooting Nursery, from seed of the double-striped kind.—B.

THE FLOWER GARDEN.

THE HARDY ARUMS.

By J. O. NIVEN, Botanic Gardens, Hull.

ALMOST contemporaneously with the Primroses, and not unfrequently associated with them, do we find the shining green leaves, peering through the Moss or Ivy-clad bank, of the wild Arum, familiarly known as "Lords and Ladies" and "Cuckoo Pint." Later on, after the broadly sagittate leaves have become developed, are produced those light green sheathing processes, popularly called flowers, but botanically spathes—in fact, they constitute a gigantic protective covering or bract, from the interior of which rises a spike, and on this spike, or spadix as it is termed, are arrayed a series of very simple unisexual flowers. In a few weeks' time the inflorescence of the Arum will be fully matured, and let me ask those who wish to claim a closer acquaintance with its structural character to pluck one of the flowers and examine it. First, it will be found, as I have just said, that what we call the flower is a sort of protective hooded cloak. Now let us examine the purple-topped axis that rises in the centre and it will be found that, beneath the base of the long smooth club-shaped terminal appendage, there are three distinct circles: the lower one consists of female flowers, possessing little more than an ovary and stigma; the middle one, which is somewhat globose in shape, consists of a few male flowers of an equally simple character embedded in the fleshy substance of the spadix, and above this is a group of tubercular processes, which are looked upon as abortive female flowers; what purpose the fleshy terminal growth is intended for we have yet to learn. From this brief examination, a clue to the flowering process of all the Arums and many kindred genera will be obtained, and that all the more clearly if the investigator has a specimen of the wild "Cuckoo Pint" in his hand. Here we find no close-fitting calyx and gaily-coloured corolla, but Nature has provided in the sheathing process a perfect substitute—protective it must be admitted to be, but it is more: it has the power of generating heat similar to that possessed by the parti-coloured corolla. This peculiarity in the flowering process was not alluded to in Mr. Bennett's admirable lecture on Fertilisation (see p. 87). I may, therefore, briefly state that the essential difference between the ordinary green leaves and the highly-coloured floral leaves of a plant consists in the fact that, whereas the former decompose carbonic acid and return oxygen to the atmosphere, the latter absorb oxygen and exhale carbonic acid; and in this process, as a matter of course, heat is generated; the plant, in fact, in flowering burns a portion of its own carbon and creates heat, the highest temperature being attained just as the anthers are ready to burst; thus we have a further and additional attraction to insect life—besides colour, odour, and nectariferous glands, we have the warmer temperature. This slight digression might at first sight be supposed to require some apology; but, when I say that the most successful experiments and the clearest proof yet adduced as to the heat-generating power of flowers were based on a series of observations made on several species of Arum and afterwards on other flowers, it will at once be admitted that it is not so foreign to our subject as might have been supposed. I have myself observed a difference of 11° between the external and internal temperature of the Arum *Draunculus*; but Vriolik, manipulating with more delicate instruments than mine, has recorded much more marked differences, extending to even 30°.

But, to return to our wild Arums, let us extend our investigations below the ground, and we shall find that the leaves and flower-spike rise from a very short underground stem, solid in texture, called a corm; these succulent processes ordinarily called roots, prior to the development of the spring growth, are charged with rich amyaceous matter, associated with a highly acrid and poisonous principle, which latter is dissipated in the process of drying. The farinaceous matter thus obtained becomes an article of commerce under the title of Portland Sago, for the manufacture of which the corms are largely collected in the south of England; and we may here remark that in Mexico, South America, India, and indeed throughout the tropics, where corms of an enormous size are

developed, they constitute an important article of food, the poisonous principle in all cases being dissipated either by pressure or by heat. I have already spoken of the broadly sagittate character of the leaves of our native plant (*Arum maculatum*) taking it as typical of the genus, or at least of a special section of it; closely related to it comes *Arum Arisarum* of the south of Europe and *A. azoricum* of the Azores; in both of these species the dark blotches, which give rise to the specific name of our British plant, are absent; the lobes of the leaves are more rounded, the terminal or fleshy portion of the spadix is cylindrical not club-shaped, and the spathe is broader, bluntly pointed, and cuneolate.

Arum italicum (the Italian Arum), with sagittate leaves similar to the preceding species, is of much larger growth; the

The Italian Arum (*A. italicum*).

principal veins are blotched with yellow, giving the leaves a marbled appearance, and as they are produced very early in the season, attaining their full development in the month of March, they form an attractive feature in the flower border. The spathe is yellowish-green in colour, fully 4 in. across—in fact, the size of that of our wild plant, the fleshy termination of the spadix being of a creamy-white colour. In the autumn, when the leaves have died away, the groups of scarlet berries, supported on foot-stalks 10 or 12 in. long, have a very attractive appearance, which they retain for a considerable time. It is a native of Spain, Portugal, Italy, and the south of France. Occasionally we meet in our own woods with a very similar variegated form of *A. maculatum*, but it is smaller in every respect than its Italian relative, which is a decidedly desirable plant for cultivation.

A. Draunculus (the Snake-stemmed Arum) attains a height, when growing vigorously, of from 2 to 3 ft.; the leaves are large,

The Snake Plant (*A. Draunculus*).

pedately divided; the petioles, sheathing round the stem, are, as well as the stem itself, of a fleshy colour, deeply and irregularly mottled with black, reminding one of the skin of a snake, whence originates its popular name of the Snake Plant; the spathe is of a deep chocolate colour, ovately-acuminate in shape, fully 8 in. across, quite smooth; the spadix is tapering, not clavate. At certain stages of floral development, a most disagreeable odour is given out by this plant, reminding one of decomposing animal matter; the emission of this odour appears to be quite spasmodic, as, at one time, it may be sufficiently powerful to cause nausea, and in a few minutes every trace of it will have disappeared. This species is a native of southern Europe, and forms a handsome and desirable border plant, so unique in its appearance as to attract the attention of even the

most casual observer. It grows freely in any ordinary rich garden soil.

A. Dracontium (the Green Dragon Arum of the Southern States of America) grows abundantly in the moist and swampy districts of Virginia and New England. Its pedately-divided leaves are elevated on foot-stalks to a height of 18 to 24 in.; these, as well as the veins of the leaves, are tinted with a deep purple; the leaflets are oblong-lanceolate and entire, the graceful curving of the veins, which is noticeable in all the species belonging to this section, adding a special charm to the appearance of the plant; the spathe is greenish-coloured, trumpet-shaped below, with a slightly hooded limb; the termination of the spadix is extended into a long gradually narrowing point exceeding the spathe in length. This handsome species is rarely met with in cultivation.

A. crinitum (the Hairy Arum) is a native of Minorca and the island of Lavezzi, situate between Corsica and Sardinia, in the former of which it is also met with, though not so abundantly. It is decidedly the most remarkable of all the hardy species, approaching more nearly to the *Amorphophallus* of Mexico and South America than any other; indeed, I am not quite clear whether it ought not more correctly to be referred to that genus. The leaves attain a height of from 18 in. to 2 ft.; they are erect, smooth, and shining, pedate in form, but with this peculiarity, that whereas the primary divisions are three in number, they are supplemented by two spur-like lobes at the base, which are each again divided into three distinct divisions; the foot-stalks are dilated into a sheathing-like process, marked with black spots at the lower part; the spathe is supported on a stout foot-stalk, which rises direct from the corm, somewhat antecedent to the full development of the leaves, and is mottled over

The Hairy Arum (*A. crinitum*).

with black blotches; it is tubular below, green-coloured and somewhat ventricose, bending at right angles just before it expands into the broadly-ovate, purplish-chocolate limb, which is fully 9 in. across by nearly 12 in. in length, the whole of the interior being lined with numerous dark-coloured, slightly adpressed hairs. The usually smooth, fleshy termination to the spadix is, in this case, covered with tubercular processes, each terminated by a slightly fleshy attenuated hair. In this species the carrion-like smell I alluded to as spasmodically occurring in the last becomes strongly and continuously pronounced, and doubtless gave rise to Linnaeus' old name of *A. muscivorum*, the smell being sufficiently strong to attract the larger flies in quest of a suitable place wherein to deposit their eggs. It is further said that the arrangement of the hairs at the somewhat contracted neck is such, that like *Averna*, whereas the descent is easy the ascent is impracticable, and hence our hairy Arum ought to take its position amongst the so-called carnivorous plants that have of late excited so much interest.

A. tenuifolium, *A. gramineum*, and *A. spirale* are three species that form a group by themselves. The first is an Italian plant, the second North African, and the third a native of China. All have narrow, Grass-like leaves, with parallel venation; the flowers are not by any means showy, nor do I deem it necessary to record more than their names, as forming a very distinct section of the genus.

A. triphyllum (the three-leaved Arum) is a native of North America, and may be taken as typical of a distinct section of the genus in which the leaves are divided into separate lobes. Here, as the name indicates, they are three in number, each lobe being broadly obovate, slightly undulate at the margin, with a sort of irregular parallelism in the venation; the spathe is trumpet-shaped below, the limb terminated by an acute point, which gracefully bends downwards over the mouth, and is of a purplish colour; the terminal portion of the spadix is club-shaped and deep purple. Much hand-

sooner than the original species is the striped variety known as *A. triphyllum zebrinum*; in it the purple colour is clearly defined into stripes, alternating with white. Neither of these plants is as frequently met with in cultivation as it ought to be; the latter is really handsome, and I believe they are both sufficiently hardy to stand our climate, at least they are uninjured in a cold frame. The want of duplicate plants has prevented me from putting their real hardiness to a practical test.

Closely allied to the *Arum*s is the genus *Amorphophallus*; possibly the species *A. Rivieri* from Mexico may not be sufficiently hardy to stand our winters, but certainly it would form a very valuable plant as a central object for a small bed in the flower garden. It sends up a stout, mottled foot-stalk to a height of from 2 to 3 ft., which expands at the top into a much divided umbrella-like leaf some 2 ft. in diameter, reminding one of a miniature Palm tree. Its use in the flower garden would combine beauty with novelty, and as such I would recommend its culture to those who are in quest of plants possessing those essential qualifications.

GARDEN VEGETATION IN JANUARY, 1876.*

By JAMES MNAB, Royal Botanic Garden, Edinburgh.

THE weather at Edinburgh during the month of January has been, upon the whole, favourable; no snow fell, although several severe snow-storms were experienced in various parts of England and in many places in the North of Scotland. On twelve mornings only was the thermometer at or below the freezing point, indicating collectively 103°, the lowest being on the mornings of the 9th, 10th, 12th, 13th, 21st, and 22nd, when 17°, 18°, 25°, 25°, 21°, and 17° were respectively indicated, while the highest morning temperatures were on the 5th, 6th, 20th, 24th, 27th, and 31st, when 41°, 40°, 40°, 41°, 42°, and 42° were indicated. During January, 1875, the thermometer was thirteen times at or below the freezing point, indicating collectively 87°. The following Table shows the amount of frost that occurred during the months of January for the last thirteen years:—

1864 . . . 39°	1863 . . . 75°	1871 . . . 168°	1874 . . . 35°
1865 . . . 194°	1869 . . . 37°	1872 . . . 42°	1875 . . . 5°
1866 . . . 40°	1870 . . . 76°	1873 . . . 63°	1876 . . . 103°
1867 . . . 210°			

This season, upon the whole, is rather in advance of the average, particularly as regards herbaceous vegetation, and certain shrubby plants. The following is the order in which those early spring plants, selected 26 years ago, for annually recording their time of flowering, came into bloom, the same plant or plants growing in similar situations being selected, so as better to compare with previous and future years:—

	1876.	1875.
<i>Tussilago fragrans</i>	January 12	January 18
<i>Hepatica triloba</i>	" 12	" 21
<i>Corylus Avellana</i>	" 14	" 15
<i>Galanthus nivalis</i>	" 18	" 21
<i>Leucojum vernum</i>	" 20	" 23
<i>Crocus susianus</i>	" 20	" 23
<i>Rhododendron atrovireus</i>	25 February 4	
<i>Erantthis hymenalis</i>	26 January 30	
<i>Daphne Mezereum</i>	26 February 4	
<i>Crocus vernus</i> , and vars.	28 "	10
<i>Galanthus plicatus</i>	29 "	3

On the rock-garden thirty-five species and varieties were counted in flower on the 31st of January, the most conspicuous being nine species of *Helleborus*, *Hepaticas* of various colours, *Leucojum vernum*, *Crocus Imperati*, *Primula denticulata*, *Erica hercynica alba*, *Daphne Mezereum*, pink and white, *Cyclamen ibericum*, and *Erantthis hymenalis*. Flowers were also to be seen on *Sternbergia lutea*, *Veronica rupestris*, and *Lithospermum fruticosum*. The comparatively mild weather, so far, has brought rapidly forward the leaf-buds of many shrubby plants, particularly those of *Roses*, *Scarlet-flowering Currants*, *Cydonia japonica*, *Nuttallia cerasiformis*—a *Hazel*, *Alder*, *Rhododendron atrovireus*, *Garrya elliptica*, *Cornus mascula*, *Jasminum nudiflorum*, &c. Among the herbaceous plants which show the greatest amount of growth at the present time is the *Elymus condensatus* (Californian Bunch Grass). The young

shoots of this, on the 31st of January, averaged fully 8 in. in length; the growths on the *Day Lily* (*Hemerocallis fulva*) were 6 in. long at the same time. The buds of several trees are also observed to be swelling fast. The quantity of catkins and flowers being produced on the *Birch* and *Elm* gives a very dark appearance to the tops of these trees. At the present time plants of *Thuja aurea* and *T. elegantissima* have parted with the brown hue usually assumed by these shrubs during the month of September. They are now (31st January) as green as they were before the brown tints commenced, and are progressing towards their usual summer golden tint. These transitions are taking place earlier this season than usual, probably owing to the brown colour not being so strong on them as is sometimes the case during more severe winters. The *Cryptomeria elegans* is also parting with its beautiful reddish winter tinge, and is now about half green; the same remarks also apply to many other Conifers, kinds which usually assume a brown hue during winter, but which regain their usual bright green colour during summer. The golden *Stonecrop* (*Sedum acre aureum*), which becomes golden during spring and summer, is still green, except in the case of a few pieces which hang down the faces of the rock-work stones, where they are fully exposed to the sun. Snowdrops are now flowering freely on all Grass lawns having a southern aspect, while those on northern slopes will be about ten days later. The Grass lawns are the only situations in the garden where their flowering can be annually depended on; when grown in borders the roots are either destroyed by mice or dug over in preparing the ground for summer flowering plants.

THE VERBENA AS A HARDY ANNUAL.

In the cultivation of the *Verbena* as a hardy annual, glass structures and fire-heat are quite unnecessary, and the amateur without any glass whatever may have beds of *Verbena* quite equal to those in gardens in which ample accommodation is provided. The seed must be sown early, and in the beds in which the plants are to remain throughout the season. It should be sown at the beginning of March. Some time beforehand dress the beds with suitable manure and dig them up to a fair depth, for a deep and moderately rich soil is most essential to the production of a fine display of flowers throughout the summer. The surface soil will require to be broken rather fine, in the same manner as for *Mignonette* or other annuals sown in spring; after the sowing has been made the surface should be raked over lightly to cover the seed with soil. The young plants will make their appearance all over the beds by the end of April, and from the first will grow with great vigour, commence to bloom very early, and continue in flower until quite late in the autumn. If any thinning be necessary it should be done before the plants suffer from overcrowding, but there should be no hurry to remove the plants when they are of a small size. The seedlings will vary more or less in colour; the mixture of colours will produce a most pleasing effect, and the perfume will be most delightful, for nearly every light flower will be as sweetly scented as the blossom of the *Honeysuckle*. To ensure a thoroughly good display, seed saved from flowers of first-class quality must be sown, and therefore, in purchasing, care must be taken to obtain seed from a strain of *Verbena* known to be good. Where the beds are required to be filled with any one particular colour the stock must be raised from cuttings, but unless they form part of a geometrical scheme mixed beds have certainly the most attractive appearance.—HENRY ECKHARD, in "Gardener's Magazine." [The above excellent suggestion is well worth carrying out. *Verbena* when growing well and free from disease are so beautiful that one cannot but regret the way in which they have disappeared from flower gardens during the past few years. Beds of good mixed *Verbena*s are among the loveliest in the choicest garden, and Mr. Eckford's plan not only points out how to raise them more simply and inexpensively than of old, but also how to secure a much more free and beautiful growth and one more free from insect-pests.]

THE FRAXINELLAS.

THESE charming old plants belong to the Natural Order of *Rutaceæ*, and the name *Fraxinella* is derived from a supposed resemblance of the foliage to that of the *Fraxinus* or *Ash*. They are fine old denizens of the mixed flower garden, and have held their position for a number of years; and such is their stately beauty, that they are not likely to be driven out by the multitude of new plants with which our flower-borders are from

* Read before the Botanical Society of Edinburgh, Feb. 10th, 1876.

time to time replenished. Had I room to grow but half-a-dozen hardy plants, one should be a *Fraxinella*; and those who have seen an old-established plant of this genus, with a dozen spikes of its white or lilac flowers, will not easily forget its striking appearance. The plant is not particular as to soil, but a moist strong soil, in a somewhat shady place, suits it best. It is easily increased by seeds, which, however, must be sown as soon as gathered, as not one in a hundred will grow if kept over till the following spring. The whole secret of cultivating these fine old plants is to leave them alone; in fact, a root of it has been known to stand on the same place for fifty years, the stem still bearing healthy blooms. The flowers, when rubbed, yield a scent like Lemons. There are

The *Fraxinella*.

about four known species; but only two are met with in general cultivation, *F. Dictamnus* (white) and the common *Fraxinella* (lilac). They are natives of the south of Europe. It is to be regretted that these fine and long-enduring plants should be so scarce in the gardens of the present day.

Bath Lodge, Ormskirk.

Tnos. WILLIAMS.

SPRING FLOWERS.

Snowdrops.—*Galanthus Elwesii*, of which Mr. Elwes kindly gave me three bulbs last year, is now in bloom, as are also *G. plicatus* and *Imperati*, and the double form of *G. nivalis*; I have them all before me on the table as I write. The single form of *G. nivalis* will not be out here for several days; *G. Elwesii* took the lead by at least a week; *G. Imperati* was the next to put in an appearance, and this was closely followed by *G. plicatus*. These last two are very much alike—at least, if I have got the true *Imperati*; I can detect little difference between them, unless it be that *Imperati* has a more slender flower-stalk, longer and narrower petals, and a more elongated ovary than *G. plicatus*. *G. Elwesii* resembles *G. plicatus* in leaf and *G. nivalis* in flower. Two or three years ago Herr Max Leichtlin sent me a fifth Snowdrop under the name of *G. Redoutei*, but the bulb was weak, and has never yet bloomed, though it now looks healthy and strong. Paxton, in his "Botanical Dictionary," gives another species under the name of *G. reflexus*, introduced in 1856, the flowers of which are said to be green, but no one seems to know anything about it. *G. plicatus* is very impatient of removal; the clumps ought not to be touched more than once in five or six years.

Crocuses.—*Crocus Olivieri*, *anreus*, *masiacus*, *biflorus*, *biflorus argenteus*, *Imperati dalmaticus*, *Weldeni*, *minimus*, *susianus*, *Sieberi*, *levigatus*, and *chrysanthus* are now, or have been in bloom during the last few days in the open ground or in pots in a cold frame. I have bloomed a single bulb each of what Mr. Baker con-

siders to be varieties of *C. chrysanthus*; one has the outside of the three outer petals clouded all over with black (I call it *nigrescens*); the other has the same, three petals flushed with rich purple and distinctly striped as in *C. susianus* in fact, till I looked at the corm, I thought it was that species. They were both found by Mr. Elwes in Asia Minor. From the same source I have flowered two bulbs of what Mr. Baker considers to be a variety of *C. Weldeni*. If so, it is a very remarkable one. The flower is even smaller than that of *C. pueillus*, in fact, the smallest *Crocus* I have yet seen; it is pure white, except that the outer side of the outside petals is clouded with black as in the *nigrescens* variety of *C. chrysanthus*. From Berlin I have a beautiful variety of *C. dalmaticus*. The outer side of its three outside petals is a rich blue purple, the inside and the whole of the three inner petals being pure white. When I can increase my one bulb into a clump, it will be strikingly effective. I am raising all the *Crocus* I can from seed. It, however, requires patience, as the seedlings are three years, and sometimes more before they bloom, but it is a sure way of increasing rare species, and there is always the chance of raising a beautiful variety. I have now pots of seed of *C. minimus*, *anreus medius*, *biflorus argenteus* and *minimus*, *Weldeni* and its varieties, *albus* and *dalmaticus*, *lineatus*, *odoros* (*longiflorus*), *levigatus*, *Kotschyannus*, *Byzantinus*, *vernus leucostigma*, *Imperati*, and *speciosus*. They should be protected from violent rain. I lost a potful of strong seedlings of *C. medius* and *Byzantinus* last autumn from leaving them out in the wet. Does any one cultivate *Crocus sulphureus albidus*? I have only a couple of very weak bulbs, and should be most grateful to any one who would exchange it for other species.

Christmas Roses.—We all owe a deep debt of gratitude to Miss Hope for the kind way in which she has distributed her fine *Helleborus maximus* or *abchasicus*, whichever it is. A plant which she was kind enough to give me when I visited Wardie Lodge in September, is now finely in bloom. It is a very fine species, totally distinct from *H. niger*. Its long reddish stigmas, to mention nothing else, at once distinguish it from that species. *H. niger angustifolius*, *atrorubens*, *niger* (type), *purpurascens*, *orientalis*, and *fœtidus*, are also in bloom.

Miscellaneous Early Flowering Plants.—*Tulipa Greigi*, with its spotted leaves, is coming up strongly; as are also *T. Oculus solis*, *fulgens*, *elegans*, *retroflexa*, *fragrans*, *Hageri*, *Julia*, *Celsiana*, *cornuta*, *Fransonianna*, *maculata*, *sylvestris*, *Biebersteinianna*, *undulata*, *folia*, *præcox*, *turcica*, *Gesnerianna*, *suaveolens*, &c. *Tulipa tricolor* which I have had for several years, is showing bloom for the first time. *Muscari Szovitzianum* is almost in bloom, and *M. Heldreichii* is close behind it. *Xiphion Histrio*, *Colchicum luteum*, *Leucocorium montanum*, *Merendera Aitchisoni* and *caucasicæ*, are all peeping, and will, I trust, soon double and treble their at present single blessedness.

Drayton-Beauchamp Rectory, Tring.

H. HARPER CREWE.

A Misnamed Primrose.—"V.'s" criticism (see p. 165) in reference to the so-called *Primula altaica*, is somewhat unjust; I wrote (see p. 122) "respecting the pretty mauve-coloured Primrose, commonly known as *P. altaica*," but I did not say that *altaica* was its proper name; indeed, I have known for some time that the *Primula* called *altaica* was not that species. It should have occurred to "V." however, that until Mr. Niven gave it a correct designation, no one knew what to call it; also that Mr. Turner had said that it was the same as the variety which he sent out twenty years ago as *P. altaica*; owing to its having been long known in the trade and also exhibited as *altaica*, I was, I think, justified in saying that "it was commonly known by that name." I trust that, in future, all will remember that it is *P. vulgaris grandiflora*. I may add, that it is unfortunate that the real *P. altaica* does not seem to be forthcoming, as a sight of it just now would be especially interesting.—A. D.

A New Cilanthus.—*Cilanthus Dampieri*, Deutsch Flagge or German Flag, was, says the "Hamburger Garteneitung," as translated in the "Gardener's Chronicle," raised by L. Vieweg, of Wegleben, near Quedlinburg, from seed; and he has now, after three years' trial, found it to be constant from seed. Instead of the scarlet with a black boss of the typical *C. Dampieri*, this variety represents the German national colours—black, white, and red. The upper part of the flower is of a fiery scarlet, the centre is a glossy, deep, bluish-black, and the keel is pure white, with a sharply-defined red margin on the lower side. The separate flowers measure 3½ in. and upwards in length, and are borne in clusters of four to seven together. In habit it agrees exactly with the ordinary *C. Dampieri*, and it is an exceedingly free bloomer. Treated as an annual it is one of the most effective outdoor plants we have. The writer of this

notice counted from 200 to 260 expanded flowers on each plant, at the beginning of August, in his garden. Its culture is of the simplest kind, and it by no means requires the nursing some people imagine. Although it flowers so freely it ripens comparatively little seed.

Hellebores from Seed.—A few weeks ago there was a good deal of controversy as to whether or not seed could be got from the Hellebore or Christmas rose. Allow me to say that I have a fine bed of it now in full flower, all the plants in which were raised by myself from a purple or plum-coloured kind; these seedlings show three or more varieties of colour, and all of them have stems from 12 to 16 in. in height, the tops of which are covered with foliage, and each bear from five to six flowers.—RICHARD WEBB, *Calcutt, Reading.*

Branches of Evergreens in Flower-beds.—I have lately seen these used in flower-beds, and with good effect. They consisted of Hollies, Yews, and similar evergreens placed with the cut ends in the ground so as to cover the soil. Small beds with Silver and Golden Hollies in the centre, edged with bands of Ivy, had a pretty effect; others, filled chiefly with common Yew and edged with the golden variety, looked equally well, and other arrangements might be made with Aucubas, berried twigs of Coneaster, little bits of the beautiful variegated *Eunymus*, and pieces of other plants. In ordinarily mild winters, or in sheltered situations, branches such as those just named, with their ends in the damp soil, retain their freshness for months, and no one could distinguish them from rooted plants. There may be no need to fill up large flower-gardens in this manner, but the appearance of small empty beds near windows might be improved by being filled with evergreens.—M.

Select Carnations and Picotees.—The following is a list of Carnations and Picotees, 12 of each, all of which I know to be among the best that are grown. I have endeavoured to make, as nearly as I can, an equal selection of new and old varieties—the new being, of course, the most expensive:—CARNATIONS: *Scarlet Bizarres*—Dreadnought, Mars (Hextall). *Crimson Bizarres*—Eccentric Jack, Isaac Wilkinson. *Pink and Purple Bizarres*—James Taylor, Purity. *Purple Plakes*—Doctor Foster, Florence Nightingale. *Scarlet Plakes*—Annihilator, Mr. Battersby. *Rose Plakes*—Mrs. Frederick Burnaby, Sybil. PICOTEES (those marked H are heavy-edged; L, light-edged; M, medium edge): *Red-edged*—Forester (H), Miss Small (H), Miss Turner (M), Mrs. Keynes' (M). *Purple-edged*—Admiral (H), Mary (L), Mrs. Little (L), Picco (H). *Rose and Scarlet-edged*—Ethel (M), Gem of Roses (H), Mrs. Fordham (M), Purity (H). *Yellow Ground Picotees*—Prince of Orange.—T. F. B. A.

Primula cortusoides.—I find what I take to be a form of this old Siberian plant, figured and described in the "Magazine of Botany and Gardening" (1836, p. 142), under the name of *P. Pallasiana*. The figure is interesting as representing an intermediate state between *P. cortusoides* and the variety known as *P. amona*, which Mr. Niven (see p. 107) thinks worthy of specific honours. The flowers are more rosy in colour, and appear larger on account of the lobes being more rounded and shallow than in the normal plant (see *Bot. Mag.*, t. 899). In the *Bot. Mag.* illustration, the upper part of the scape is shown as smooth; but in the other engraving mentioned above it is decidedly hairy throughout its entire length. It is now well known to horticulturists that many of the plants introduced by us from Japan, and described as species, are merely cultural forms of plants long ago introduced by the Japanese from other parts of Asia and America, and of which doubtless, as suggested by Mr. Niven, this *Primula* and its sportive forms are examples.—B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Purple-leaved Nut.—Allow me to endorse Mr. Muir's remarks (see p. 152) respecting this Nut, the leaves of which are more than double the size of those of the Purple Beech. It makes an effective plant in shrubberies.—R. GREENFIELD, *Privity Gardens, Warwick.*

Transmission of Cuttings (see p. 87).—Where cuttings of tender plants have to be carried in the hand or pocket, the best plan is to place them in a small empty flower-pot, and wrap it up in paper. A large quantity of them may be put into a 3-in. pot, in which they do not get crushed as they do when tied up in paper. Small quantities of choice flowers may also be safely carried in the same way.—J. MUIR.

Autumn-struck Alternantheras Best.—Allow me to supplement the note on Alternantheras (see p. 150) by saying that old plants lifted from the beds in autumn never winter so satisfactorily or are so good to propagate from in the spring as cuttings struck in September. As a rule, old plants run to flower in the spring, and are then comparatively worthless for propagating purposes, but not one in a thousand of young plants manifests any tendency to bloom.—W. W. H.

THE LIBRARY.

ANGOLA AND THE RIVER CONGO.*

This interesting work, the result of many years of travel and exploration, gives a vivid and intelligent account of the country which it describes—a country peculiarly interesting to horticulturists. The author does not profess to be a botanist in any sense, and yet there are many observations on vegetation in the book of much interest. The country is rich in plants, but has some of its surface as barren as many of those dreary-looking tracts which figure so often in our illustrated journals. The coast line for example, consists of level sandy bays, fringed by belts of Mangrove, alternating with long stretches of cliffs covered with a coarse branching *Eragrostis*, tall Cactus-like *Euphorbias*, and gigantic Baobabs, covered with long Gourd-like fruits. At some distance from the sea, however, very different scenes occur.

"I may state," says the author, "that from the River Congo to Mosamedes no dense forest is seen from the sea, and from thence not a single tree, it is said, for hundreds of miles to the Orange River. A little Mangrove, lining the insignificant rivers and low places in their vicinity, is all that varies the open scrub, of which the giant *Adansonias* and *Euphorbias* have taken, as it were, exclusive possession. Nowhere on the coast is seen more than an indication of the wonderful vegetation, or varied beauty and fertility, which generally begins at a distance of from 30 to 60 miles inland. At this distance, a ridge or hilly range runs along the whole length of Angola, forming the first elevation; a second elevation succeeds it at about an equal distance; and a third, at perhaps twice the distance again, lands us on the central high plateau of Africa. From the few and insignificant streams traversing Angola to the coast, which at most only reach sufficiently far inland to have their source at this third elevation or central plateau, it would seem that a great central depression or fall drains the waters of that part of Africa in either an easterly or southerly direction. I think it is very doubtful whether the Congo, with its vast body of water and rapid current, drains any large extent of country in an easterly direction to the interior, beyond the first rapids. The successive elevations inland, to which I have alluded, are accompanied by very remarkable changes in the character of the vegetation covering the surface of the country. These are due, I believe, as Dr. Welwitsch has pointed out, to the difference of elevation alone, irrespective of its geological formation. A sketch of the vegetation of the country traversed by the road from Ambriz to Bembo, where is situated a wonderful deposit of malachite—a distance of about 120 miles E.N.E.—will give an idea of the general character of the change observed in travelling towards the interior of Angola. For about 25 miles from Ambriz the vegetation is, as already described, principally composed of enormous Baobabs, *Euphorbias*, a tall *Agave* (or Aloe), a tree called "Muxice" by the natives, bearing curious seed-pods (*Sterculia tomentosa*), a few small slender creepers, great abundance of the *Sansevieria Angolensis* in the thickets of prickly bushes, and coarse, short, tufty Grasses—the branching Grass being only found near the coast for a few miles. The country is pretty level, dry and stony, of weathered large-grained gneiss. At Matuta the scene suddenly and magically changes, and in so striking a manner as to impress even the most unobservant traveller. The Baobabs become much fewer in number, the *Agaves*, the *Sansevieria*, the *Euphorbias*, suddenly and almost completely disappear, as also do most of the prickly shrubs, the fine trailing and creeping plants, the Muxice, and several other trees, and a number of smaller plants. A new set of larger, shadier trees and shrubs take their place, the Grass becomes tall and broad-leaved, and one seems to be travelling in an entirely new country. This character is preserved for another stretch of road till Quiballa is reached, about 60 miles from the coast, where the rise in level is more marked; and again the vegetation changes almost as remarkably as at Matuta, where, however, the difference in altitude is not so sudden, but a gradual rise is noticed all the way from Ambriz. Creepers of all kinds, attaining a gigantic size, here almost monopolise the vegetation, clasping round the biggest trees, and covering them with a mass of foliage and flower, and forming most exquisite festoons and curtains as they web, as it were, one tree to another in their embrace. No words can describe the luxuriance of these tree creepers, particularly in the vicinity of the shallow rivers and rivulets of the interior. Several trees together, covered from top to bottom with a rich mantle of the India-rubber creeper (*Landolphia florida* ?), with bright, large dark-green leaves, somewhat resembling those of the *Magnolia*, thickly studded with

* "Angola and the River Congo," by Joachim John Monteiro. With Illustrations. 2 vols. Macmillan & Co., London.

large bunches of purest white Jasmine-like flowers, loading the air for a considerable distance with its powerful Bitter Almond perfume, and attracting a cloud of buzzing insects, form altogether a sight not easily forgotten. Once at Bombe I saw a perfect wall or curtain formed by a most delicate creeper, hung from top to bottom with bottle-brush-like flowers about 3 in. long;—but the grandest view presented to my eyes was in the Pango Audongo range, where the bottom of a narrow valley, for quite half a mile in length, was filled, as they all are in the interior, by a dense forest of high trees; the creepers, in search of light, had pierced through and spread on the top, where their stems and leaves had become woven and matted into a thick carpet, on which their flowers were produced in such profusion that hardly a leaf was visible, but only one long sea of beautiful purple, like a glacier of colour—filling the valley, and set in the frame of green of the luxuriant Grass-covered hill-sides. I have seen the surface of a large pool of water thickly covered with a layer of purple Pea-shaped flowers, fallen from the large Wistaria-like bunches of blossom of a creeper overgrowing a mass of trees standing at the edge; it seemed as if Nature, loth that so much beauty should fade quickly, had kept for some time longer the fallen flowers fresh and lovely on the cool still water of the shady lake. This

months in the year take undisputed possession of the country and actually interrupt all communication in many places.

It will be seen from the above that Mr. Monteiro has the power of describing what he sees more than most of the writers of books of travel. We have not had the advantage of seeing aspects of vegetation in Africa; but, from analogy with what we have observed in other countries, the sketch of the gradually rising hills and changing vegetation seems singularly happy. The book is not confined to general descriptions, but tells how the author has enriched our gardens with at least one good plant.

Camoensia maxima.—At Quiballa we were fortunate enough to obtain flowers and ripe seeds of the beautiful plant named *Camoensia maxima* by its discoverer, Dr. Welwitsch. We saw it growing along the sides of the road as soon as we left the gneiss formation and entered on the mica slate, but most abundantly in the more bare places on the sides of the hills at Quiballa, in the very hard clay of the decomposed mica slate. The *Camoensia maxima* grows as a hard, woody bush, with rather straggling long branches covered with fine large leaves, and bearing bunches of flowers, the

Welwitschia plants in Argola (see p. 178).

abundance of creeping plants is more or less preserved till at about 60 miles farther inland we arrive at Bombe and the comparatively level country stretching away to the interior; the Oil Palm (*Elaeis Guineensis*) then becomes again abundant, these trees being only found on the coast in any number in the vicinity of the rivers; the beautiful feathery Papyrus also again covers the lagoons and wet places. The comparatively short and spare, thin-leaved, and delicate-tufted Grasses of the first or littoral region are succeeded in the second, as I have already said, by much stronger kinds, attaining an extraordinary development in the highest or third region. Gigantic Grasses from 5 to much as 16 ft. high, growing luxuriantly, cover densely the vast plains and tracts of country in these two regions where tree vegetation is scarce. The edges of the blades of most of these tall Grasses are so stiff and finely and strongly serrated as to be quite sharp, and if passed quickly over the skin will cause a deep cut, as clean as if done with a knife; one species is called by the natives "Capin de faca" in Portuguese, or "Knife Grass," from the manner in which it cuts if handled, or in going through it. To anyone accustomed to Grass only a few inches high, the dimensions that these species attain are simply incredible. Like snow and ice in northern latitudes, Grasses in interior tropical Africa for some six

lower, and by far the largest petal of which is shaped like a shell of a delicate creamy-white, with its edges exquisitely crimped, bordered with a golden rim, and nearly the size of an open hand. Its shoots spread underground to great distances and shoot out into other plants, so that on attempting to remove what we thought nice small plants, we always came on great thick roots which we followed and found to proceed from old bushes at a considerable distance. Several small plants that we brought away alive died subsequently at Ambriz. Half-a-dozen of the seeds germinated on arrival at Kew Gardens, so that I hope this lovely flower will be shortly in cultivation—a welcome addition to our hot-houses. All the plants that we collected and dried are deposited in the herbarium at Kew Gardens.

Palms, Baobabs, and Birds.—Beyond Maxima the river becomes really charming. A panorama of mile after mile of the most beautiful dark forest of high feathery-topped oil Palms stretches on both sides, but principally on the north bank. Under the shade of these Palms is seen a succession of picturesque huts, in every variety of unsymmetrical quaintness, of weathered Grass roofs, mud walls and whitewash, and crooked doors and windows. Many of these huts are embosomed in a fence of growing Hog-plum stakes, and surrounded by a thicket of Lime and Orange trees, Plantains,

Papaws, &c., the luxuriant and ever bright green foliage contrasting beautifully with the sombre almost black hue and shade of the Palms. Where there are no Palm trees the vegetation is equally lovely, a profusion of creepers festooning and covering the highest trees. Amongst these the Cotton-wood trees and giant Baobabs are the most conspicuous, their sparsely-covered branches generally crowded with hundreds of long-legged herons and other birds. One of these vast trees with but few leaves, and the branches thickly covered with lines of long-legged and long-necked grey or white birds standing bolt upright, has a most extraordinary and unexpected appearance. The Palm forests resound with the cooing of innumerable doves, and are a favourite haunt of a white-headed eagle or vulture, complained of by the natives for the havoc that it commits on the Palm Nuts, on which it is said chiefly to subsist. The Palm tree is also the favourite resort of several species of the beautiful little nectarinae or sun-birds, who appear to find on the crown and leaves the small spiders and other insects that constitute their principal food. They are always especially busy about the gourds placed at the tops of the trees for the purpose of collecting the Palm wine; whether it is that they are fond of the juice, or whether this attracts the insect prey they are in search of, I know not. Palm trees standing alone generally have as many as a hundred or more of the pretty nests, made by a species of weaver-bird, suspended from the leaflets. These birds are very noisy, and take not the least notice of the people passing beneath—in fact, they seem to prefer building their nests in solitary Palms in the middle of a native town. The natives never think of molesting small birds, and the children have not the propensity for stone-throwing or bird-stinging that our more civilised boys have.

Vegetables and Fruits.—The soil about Bembe is very productive. Sugar cane grows to a large size, and vegetables flourish admirably. Greens of all kinds and Cabbages grow beautifully, although the latter seldom form a hard head; all kinds of salad grow equally well, such as Endive, Lettuce, Radishes, Mustard and Cress, &c.; Peas, Turnips, Carrots, Mint, and Parsley also flourish, and Tomatoes, larger than I ever saw them even in Spain and Portugal. Cucumbers, Melons, and Vegetable Marrows; we obtained very fine the first season, but the succeeding year a swarm of very small grasshoppers prevented us from getting a single one. Broad Beans, although growing and flowering luxuriantly, never produced pods. It is almost impossible to estimate the advantage, in a country and climate like Africa, of an abundant supply of fresh salad and vegetables, and yet, although growing so luxuriantly, and with so small an amount of trouble, they are never cultivated by the natives of any part of Angola, and rarely by the Portuguese; the market at Loanda, for instance, is very badly supplied with vegetables.

Benguela and Mossamedes—particularly the latter—are the only exceptions to the general and stupid want of attention to the cultivation of vegetables. The only vegetable introduced by the former missionaries that still exists in cultivation in the country is the Cabbage, which is sometimes seen in the towns (generally as a single plant only), growing with a thick stem, which is kept closely cropped of leaves, and as much as 4 or 5 ft. high, surrounded by a fence to keep the goats and sheep from browsing on it, but I have never seen it in their plantations. Bananas, or Plantains grow magnificently, as might be expected, and without requiring the least trouble. They are principally grown in valleys and other places, where the rich, moist earth in which they delight is found, and where, protected by Palm and other trees, they rear their magnificent leaves unbroken by a breath of air. A grove of Banana trees thus growing luxuriantly in a forest clearing is one of the most beautiful sights in Nature;—the vast leaves, reflecting the rays of the hot sun from their bright-green surface, contrast vividly with the dark-hued foliage of the trees around, and show off the whorls of flowers with their fleshy, metallic, purple-red envelopes and the great bunches of green and ripe yellow fruit. Numbers of butterflies flit about the cool stems and moist earth, whilst the abundant flowers are surrounded by a busy crowd of bees and other flies, and by lovely sunbirds that, poised on the wing in the air, insert their long curved beaks into the petals in search of the small insects and perhaps honey that constitute their food. The negroes of Angola always eat the Banana raw, but it is roasted by the whites when green, when it becomes quite dry and a good substitute for bread, or boiled, to eat with meat instead of Potatoes; and when ripe, roasted whole, or cut lengthways into thin slices and fried in batter and eaten with a little sugar and cinnamon or wine, forming a delicious dish for dessert. A very large Plantain, growing as long as 18 or 20 in., is cultivated in the interior, and is brought down to the coast by the "Zombos" with their caravans of ivory. Indian Corn is the only other plant that is grown and used as food by the negroes of Angola, with the exception of the Ground Nut. It is sparingly

cultivated, though bearing most productively, and is eaten in the green state, raw or roasted, and sometimes boiled. About Loanda the dry grain is occasionally pounded into meal and boiled into a stiff paste with water, and eaten in the same manner as the "infundi" from the Mandioca root. Other edible plants, though not much cultivated by the natives, are the Sweet Potato; the common Yam (which is very rarely seen and I am quite unable to give a reason for its not being more commonly cultivated); the Cajanus indicus, a shrub bearing yellow Pea-like flowers and a pod with a kind of flat Pea, which is very good eating when young and green; the purple Egg-plant, or "Berenjela" of the Portuguese; and the "ngilló" (Solanum sp.), bearing a round Apple-like fruit, used as a vegetable; the ordinary Pumpkin, and a small Gourd; and, lastly, the "Quiavo" or "Quingombó" (Abelmoschus esculentus) of the Brazilians.

Garlic I consider a most valuable article of food in a hot climate, especially eaten raw. I never travelled without a supply of Garlic, and I found its beneficial effects on the stomach and system most marked. When very hungry and fatigued I have found nothing to equal a few pieces of raw Garlic, eaten with a crust of bread or a biscuit, for producing a few minutes after a delightful sensation of repose, and that feeling of the stomach being ready to receive food, generally absent when excessive emptiness or exhaustion is the case.

Welwitschia and Cotton-wood Trees.—About Mossamedes that most singular plant the *Welwitschia mirabilis* is found growing, and the country about the River San Nicolau, or 14° S. lat., seems to be its northern limit. It has been found south, in Damara Land. I was fortunate enough to be able to collect specimens of the plant, flowers, and cones for Dr. Hooker, which supplied some of the materials for his splendid monograph on this wonderful plant. These specimens are now preserved in the Kew Museum. At Cazengo I saw the largest trees I have ever seen, and conspicuous amongst these was the Cotton-wood tree (*Eriodendron anfractuosum*), towering to an immense height straight as an arrow, without the slightest break, to the small branches at the very top covered with feathery-looking foliage, and studded with puffy balls like white silk, from the burst seed-pods. The stems and branches are thickly studded with hard, short, conical, sharp-pointed spikes, and at the base of the stem vast flattened buttresses project, which give a wonderful idea of strength and stability. Coffee is found growing wild in these virgin forests, but it is confidently believed to have been originally introduced by the old missionaries, and since been spread by the agency of monkeys and birds. At Bruto there is a fine lagoon in which abundance of fish is netted, and there are some lovely woods and valleys. A little bay in the river near Bruto was covered with the leaves and flowers of the Water Lily (*Nymphaea dentata* and *stellata*), and trailing on these were long stems of a plant many yards in length, covered with bright green leaves and lovely purple bell-shaped flowers. About Bembe a handsome creeper (*Mucuna pruriens*), with leaves like those of a Scarlet Runner, and bearing large, long bunches of dark maroon Bean-like flowers, grows very abundantly. The flowers are succeeded by crooked pods covered with fine hairs (cow-itch) which cause the most horrible itching when rubbed on the skin. The first time I pulled off a bunch of the pods I shook some of the hairs over my hand and face, and the sensation was alarming, like being suddenly stung all over with a Nettle.

The book is full of interest, and we can confidently recommend it to all who are interested in the vegetation, fauna, and general characteristics of the part of Africa to which it refers.

Experiences of an English Buyer of Land in France.*

—This is a curious pamphlet explaining the difficulties, extortions, and annoyances to which an Englishman purchasing a small property in the south of France was subjected by his neighbours, lawyers, and others. It is of interest to such as contemplate settling in the Mediterranean regions of France.

Warne's Victoria Toy Books.†—This is a very praiseworthy little series of publications by the Messrs. Warne. There are twelve distinct and well illustrated little books, each devoted to the illustration and description of a separate branch of the Animal Kingdom, and united in one wrapper. The illustrations are well designed and delicately coloured. An edition of 100,000 copies of this series has recently been printed. It is one of the most interesting examples of modern colour-printing, and is a credit to the spirited publishers who have produced it.

Standard Measurement.—The Warden of the Standards has, it appears made arrangements for laying down on the north side of Trafalgar Square, a legal standard of the surveyor's chain, 66 ft., and of the builder's chain, 100 ft., and for fixing the mural standards at the same site.

* Ridgway, Piccadilly.
† Warne, Bedford Street, Covent Garden.

TREES AND SHRUBS.

EVERGREEN BANKS.

A LAUREL bank is a common feature in most gardens, and a commendable one it is, for it is often practicable to cover a slope with shrubs where Grass would not grow, or perhaps would not be desirable. The formation of such a bank is a simple matter; it is only necessary to plant thickly enough, and afterwards to keep the shrubs at the desired height by regular pruning. Sometimes, however, such plantations are allowed to grow as they please, and in a few years they become an irregular thicket, and the question arises how to deal with them. The process is a summary one, and consists in cutting the trees down to the desired level; if there be blanks to fill up, a ready way of doing so is to saw the tall limbs of the nearest trees half through or more near the ground and bond them down, pegging their points well into the ground with strong pegs. There is no danger of these broken limbs dying if a little bit of wood and bark be left at the cut, and they will soon root at the peg, and a fresh and vigorous growth of young shoots will push from the limb along its entire length. We have seen acres of Portugal and common Laurels operated upon in this way with perfect success. Shrubberies of Laurel, which have got too high and lanky, in any situation, may be restored in this way, unless the trees are very old or feeble. The Laurel is not, however, the only eligible plant for covering banks; and, among others, must be named the Ivy, which makes an excellent covering, thriving in any aspect, and growing on places where the soil is too thin or too poor to sustain a good Grass turf, or even on bare rock. It should be planted pretty thickly at first, and trained over the surface to be covered for the first season; afterwards it will take care of itself, but it should be cut in close to the ground every spring with a pair of shears in order to keep an even surface. Nothing makes a denser or a greener sheet than Ivy so treated, and if the soil be not too rich the leaves will not get very large; they look best when numerous and small. The great thing is to clip it well in. We have seen it shorn bare to the naked wood annually for many years with great advantage, and if the operation be performed about the beginning of April it will not be long leafless, for it then breaks into leaf immediately. Another plant adapted to our purpose is the Cotoneaster microphylla; its pretty and numerous white flowers, its dark green shining foliage, and in autumn and winter its never-failing crop of red berries, render it a general favourite for walls, and it does equally well, or better, trained on the ground. It should be pegged close to the ground, and, when it has covered the allotted space, the more it is cut with the shears the denser it will grow. The young growths will require to be cut back once or twice during the summer, taking care not to damage the berries, which will then be coming to maturity. Clipping, if done with ordinary care, will not hinder it from flowering and fruiting freely, but rather promote a bearing habit, as the topping of the young growths has the same effect upon it as summer pinching has upon fruit trees. We have this plant upon a wall here, nearly as dense as a carpet, and not above 1½ in. deep, and at present so thickly studded with its beautiful berries that you can hardly insert your fingers anywhere without touching them, notwithstanding that the birds have had their share during the winter. Hardly less suited for banks than the above, is the evergreen scarlet-berried *Crataegus Pyracantha*, succeeding with much the same treatment as the Cotoneaster, and growing much faster, but not bearing its bright scarlet berries in such profusion until it gets a few years old. Pinching, however, and a not over-rich soil, will promote early fertility, and when it does bear freely there is no winter-berried plant which is so effective, for it is nearly as bright as a scarlet Pelargonium. Next to these comes the popular *Laurustinus*, second to none as a flowering evergreen; it is also an accommodating subject, and will grow easily enough if clipped; but not to lose the flowers, and yet to keep an even surface, it should be pruned just after flowering, and at no other period, otherwise the little terminal trusses will not have time to form before winter; of course straggling shoots may be cut out at any time. Among other less suitable evergreens are *Berberis Darwinii* and others, the *Boxwood*, *Pernettya mucronata*, and perhaps a few others. Indeed, any evergreens that will bear clipping may be employed; but we have named the best. Any of the above may be used either singly or in combination; for example, each kind may be planted in lines, beginning with the most robust growing at the back, and terminating with the dwarfier species in front. The Ivy may be used in the shade, where neither Grass nor the other shrubs will thrive, unless, perhaps the Cotoneaster, which does tolerably well in the shade, though it grows more straggling. Last, but not least, says a writer in the "Field," from which these remarks are taken, we had nearly forgotten the *Aucuba japonica*, which is one of the best subjects to deal with; but it must be pruned with the knife, and not clipped.

Effect of Gas on Tree Roots.—Mr. J. Bernhard Smith brings us ("Field") a portion of the root of a tree to show the effect of the escape of gas from the mains into the soil. It is part of a root of a tree dug up in Piccadilly, in order to plant a young tree in place of one that has died. Some fresh mould was put into the hole, and another young tree planted. The wood is quite fœtid from being saturated with gas, and well shows the way in which London soil is poisoned for tree life.

Poisoned by Evergreens.—An extraordinary case of vegetable poisoning has been investigated by Mr. Dunstan, corner, at the Parkside Asylum, Macclesfield. Emma Linnell, who had been a patient in the asylum since last June, became suddenly ill, and died apparently in an epileptic fit. A post-mortem examination was held, and about a teaspoonful of green fluid was found in the stomach, with some Holly seed. There were also some Yew leaves, which had been in the stomach only a short time, and fragments of either Laurel or Holly leaves. A verdict in accordance with the evidence was returned, Dr. Deas saying this was the first case of the sort in his experience.

The Bay and Arbutus in Greece.—*Laurus nobilis* was, in ancient times consecrated to Apollo, hence it is called *Laurus Apollonis*. This handsome tree is met with in the forests of Greece, and is extensively cultivated in the gardens of cloisters. The seeds of this tree resemble those of the Olive, known here by the name of *Daphnekoumik*. The seeds could be utilized for obtaining the highly aromatic fixed oil, which I (a Greek writer in the "Pharmaceutical Journal") have often expressed, and consider more aromatic than the oil obtained from the Bay raised in other localities. It seems as if in warmer climates the aromatic principles of plants were more profusely developed, like the bitter and astringent principles in colder regions. *Arbutus Unedo* is a beautiful tree found in all the forests of Greece, and an ornament of the Oriental gardens. The excellent fruit of this tree resembles a large Strawberry, and is collected by the poor and sold during the winter; it has a pleasant taste, but in large quantities it is apt to produce indigestion. In some parts of the country a spirituous liquor, called *Paki*, is obtained from the fruit by fermentation.

Berry-bearing Aucubas.—All your correspondents seem to have overlooked the important fact that male and female Aucubas rarely happen to be in bloom at the same time when planted side by side in the open air, and this appears to me to be the chief reason why the males are so generally grown in pots, and either forced in heat or retarded, as the exigencies of the case may require, since the success of fertilisation, of course, depends on the two sexes being in bloom at the same time; should the male plants bloom first, the pollen can be preserved in clean paper for a week or two until the female bushes are in flower. It may interest some of your readers to know that about an equal proportion of male and female plants results from a batch of seed or berries; but, as pointed out some time ago by M. Carrière, there is often a difference of from one to two months between the blooming of male and female plants thus raised; hence, it follows that budding, grafting, and even planting male and female bushes side by side are not always successful in producing proper fertilisation, although some instances of such may be noted. It seems to me that there are both early and late flowering male as well as female Aucubas, and this may explain the different accounts given by various cultivators. It is possible that in some cases the early flowering habit of the male plants may have been caused by several years of culture in a greenhouse temperature.—B.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Fruit of Enonymus.—Of all berry-bearing shrubs none excels the *Enonymus*, sometimes called Burning-bush, and Strawberry-bush, with its brilliant scarlet seed covers. When associated with evergreens, nothing can be more striking than its beauty and brilliancy.—J. J. THOMAS.

The Fever Gum Tree in Derbyshire.—I have two plants of *Eucalyptus globulus* in large pots about 10 ft. in height, and about eight years old. What would be best to do with them? They are too large for house room. Would they succeed planted out in the open ground?—E. B. [Not in Derbyshire, we fear, except perhaps on a conservative wall and protected in winter.]

The Winter Honeysuckle (*Lonicera fragrantissima*).—This is a good companion for *Chimonanthus fragrans* and *Jasminum nudiflorum*, on walls, flowering, as it does, in the open air in mid-winter, and continuing for many weeks to afford a supply of its fragrant blossoms. In mild districts it will thrive on sunny banks in good open soil.—B.

Large Plank of Cypress Wood.—A timber merchant in New Orleans has, I read, on exhibition a Cypress board from Alabama, which is 13 ft. long, 8½ in. wide and 2 in. thick, and is without knot or split. The tree from which the timber was taken must have measured at least 7 ft. in diameter. I suppose this to be the deciduous Cypress?—T. G. B.

PLATE VIII.

EARLY ASCOT FRONTIGNAN GRAPE.

Drawn by H. HYDE.

It has been the fashion of recent days, before offering to the public a new variety of any kind of fruit, to obtain for it a first-class certificate from the Royal Horticultural Society. It is not too much to say that these certificates are sometimes calculated to mislead. A few Committee men meet at South Kensington to pass judgment on the selections sent for their approval; and it is possible that the presence of some of the growers adds zest to the meeting. A number of fine specimens await their decision: how delicate is the soft bloom on the Grapes! how rich and luscious the taste! how fine the berries! A certificate cannot surely be refused to such a specimen! it will be a great gain to the pomologist. And so the new comer goes out into the world, sponsored and praised by men, who, after all, know little or nothing of its real merits. "All is not gold that glitters" is true of fruits. Many a grower has found to his cost that he has been deceived by a high-sounding name, and that many of the qualities for which the new Grape has been hastily commended, are entirely absent, or only to be brought out under exceptionally favourable circumstances. Grapes like these are not suitable for general cultivation; their constitution is too fragile—their crops too uncertain for any growers but those to whom time, expense, and trouble are of no importance. "I chose my wife," said the Vicar of Wakefield, "as she did her wedding gown; not for a fine glossy surface, but for such qualities as would wear well." Let me not, however, be supposed to undervalue the approval of the Committee in question. I merely complain that they pass judgment upon the fruits submitted to their notice without subjecting them to sufficiently searching tests. It is surely not enough to grant a certificate after seeing and tasting a specimen grown for exhibition under the most favourable circumstances, with every advantage of soil and climate—the Committee should have had the opportunity of becoming personally acquainted with the plant, its growth, and peculiarities.

There are fruits, "to fortune and to fame unknown," outside the pale of the Royal Horticultural Society, which yet have some title to the favourable consideration of growers, and it is to one of these that I would direct the attention of your readers. The annexed plate represents the Early Ascot Frontignan, a Grape which has never been advertised, and is little known to the public, but which I believe to be a valuable contribution to every Grape-grower's collection. It is remarkably early; when grown under the same conditions as the Black Hamburg, it ripens fully a month earlier than that variety. It is suitable for pot culture in an early vinery, and does well on a wall in the open air. The bunches are moderately large, slightly shouldered; the berries round, medium sized, and of a clear amber colour; the flesh tender, extremely sweet and luscious, with a fine Frontignan flavour. It is a hybrid raised by the late Mr. Standish, of Ascot, by fertilising the Muscat Blanc de Saumur with the Chasselas Musqué. It is truly a summer Grape, deriving its precocity and fruitfulness from the first-named parent, its flavour and constitution from the latter. The scion has well repaid the skill of the careful cultivator.

And here let me pay a passing tribute to the memory of John Standish, a man whose name is foremost among the practical horticulturists of our day, and one who has accomplished so much in the art to which the latter part of his life was dedicated. Some twelve years ago he removed from Bagshot to a nursery on a more extended scale at Ascot, and there devoted most of his time, and the valuable experience he had gained by years of study, to the improvement of our fruits and flowers. In this he was most successful, especially in raising new varieties of Rhododendrons, Garden Peas, Strawberries, Peaches, and Grapes. The Early Ascot Frontignan, and its companion the Royal Ascot, the black offspring of two white parents (the Bowood Muscat and Trouvéren), and itself remarkable as an early useful Grape, remain lasting monuments of his ability and skill. An accomplished hybridiser, Mr. Standish did not,

however, confine himself to practice, but kept careful records of his experience for the benefit of those who shall hereafter tread in his steps. The papers from his pen, which appeared from time to time in the leading horticultural journals, bear witness to his talents, improved by habits of study and observation.

The best White Grapes.

It is somewhat difficult to make a selection from the great number of White Grapes now in cultivation, much depending upon the conditions under which they are to be grown. It is not to be expected that a Sweetwater or a Muscadine can bear comparison with Muscat of Alexandria, yet each Grape has its own peculiar advantages. In a small collection, where there is no provision made for great or continuous heating of the vinery, those marked with an asterisk (*) in the early part of the following list are most suitable. These, however, are not good after October. The remainder come in afterwards, require more heat, and remain in perfection for some months longer. As a rule, all late Grapes require more artificial heat to ripen them properly than early ones. The nature of soil and varying modes of treatment have an important influence in determining the peculiar form of the Grape; sometimes the same Grape has several different synonyms, but the following are the generally recognised names:

* **Early Ascot Frontignan.**—One of the best and earliest of White Grapes; it is fully described above. This Vine, though very little known to gardeners generally, has shown that its produce is very valuable. To prove it, canes were distributed by the late Mr. Standish among his friends, but, unfortunately, after his death no record could be found of their names. His surviving partner (Mr. Ashby) would be extremely obliged if those who have canes would communicate with him on the subject.

* **Royal Muscadine.**—Bunches, long, loose, and shouldered; berries, large and round; skin, thin and transparent, greenish-yellow, and when quite ripe, pale amber sometimes marked with tracings of russet, covered with a thin white bloom; flesh, tender and juicy, sweet, and richly flavoured. This excellent Grape will ripen in a cold Vinery and against a wall in the open air, and is easily cultivated. It is grown under a variety of names, such as the Chasselas de Fontainebleau, White Muscadine, Early Chasselas, &c. The various forms it frequently assumes are occasioned entirely by the nature of the soil and the different modes of treatment to which it is subjected.

* **Chaptal.**—Bunches larger than those of the Royal Muscadine; berries large and round, inclining to oval; skin, white, and when quite ripe, transparent; flesh, juicy and sweet. This new Grape is of excellent quality, and well adapted for a cool vinery. The Vine is a free and prolific bearer. It is also suitable for pot culture.

Duke of Buccleuch.—Bunches, large, ovate, from 8 to 10 in. long with large broad shoulders; berries, enormously large; skin, thin, of a rich amber colour, when fully ripe; flesh, tender, juicy, and pleasant. This is comparatively a new Grape, and is the largest-berried white variety we have. It and its companion, the Golden Champion, succeed well with the same treatment as the Black Hamburg.

* **Golden Queen.**—Bunches, 9 in. long, with a stout stalk, long, tapering, and well shouldered; berry stalks, rather long; berries, oblong or oval; skin, of a clear amber or golden colour; flesh, firm, very juicy, and richly flavoured. This fine new Grape has an excellent hardy constitution, and will be very popular when it is better known.

* **Foster's White Seedling.**—Bunches, large, and well set; berries, rather large, roundish-oval; skin, greenish-yellow, becoming clear amber when ripe; flesh, tender, melting, very juicy, sweet, and richly flavoured. A fine showy Grape, of first-rate quality. It ripens at the same time as the Royal Muscadine, and is considered by some growers to be superior to it. It succeeds well for early forcing.

Muscat of Alexandria.—Bunches large, long, loose, and shouldered; stalk long; berries large, oval, and unequal in size; skin thick, generally a greenish yellow, but when highly ripened a fine pale amber colour, covered with a thin white bloom; flesh firm, not very juicy, but exceedingly sweet and rich, with a fine Muscat flavour. This is the most useful of all the white Muscats, and bears a more certain and regular crop. It is a most delicious Grape, requiring a high temperature to ripen it thoroughly. The Vine is an abundant bearer, but the bunches often set badly. To remedy

this defect, it is a good plan to draw the hand down the bunches when they are in bloom, so as to distribute the pollen and thereby aid fertilisation. It is this Grape which produces the Muscatel raisins imported in boxes from Spain.

Baisin de Calabre.—Bunches large, slightly shouldered, long and tapering, sometimes upwards of a foot in length. It is not first-rate as to flavour; but is, nevertheless, a good Grape to grow on account of its late-keeping qualities.

The Bowood Muscat and Cannon Hall Muscat are good Grapes and seedlings from Muscat of Alexandria.

Delicately-flavoured Grapes, and especially early ones, should be eaten as soon as they are ripe. Like the Pear, the period when they are in perfection is soon over, and, when once past the brisk vinous flavour gives place to a mawkish sweetness. It is too often the practice to grow early and late-keeping Grapes in the same vinery, and using the same treatment, to expect both to be fit for the table at the same time. It is hardly possible to make a greater mistake. In an early summer Grape you look for a thin-skinned, refreshing, juicy fruit; but, in the late varieties, it is necessary to have something

its allotted work, pruned often, and its shoots kept free and open. Remember that no branches, no leaves; no leaves, no roots. Great attention should be paid to the airing of the house, which must be done gradually, so that there may not be at any time a sudden change in the temperature. A great deal of moisture is required, and the Vines often suffer to a considerable extent from the want of it, especially with a well-drained border. Moisture must be continued until the berries have completed their last swelling, when it should be withdrawn. With attention to these points, and the prerequisites of a rich border on a dry sub-soil, good crops of Grapes must always be obtained and healthy Vines secured.

Hillside, Newark.

W. NEWTON.

DURATION OF RASPBERRY BEDS.

THE question is often asked, "How long will a plantation of Raspberries continue remunerative?" To this a satisfactory answer can scarcely be given; for, even under apparently similar circumstances, one bed will continue production for

Baobab trees and gigantic Euphorbias (see p. 178).

solid and fleshy, which gains rather than loses by keeping. It follows, as a matter of course, that Vines similar in growth and time of ripening should be planted in the same house. Were the natural habits of the Vine more attentively considered, we should have fewer complaints of ragged bunches, uncoloured, unequal-sized, and seedless berries, with sloughing and mouldy skins. With more careful cultivation we should have less mildew, red spider, and other evils—the despair of gardeners. No plant is so grateful as the Vine, or so well repays the cultivator. When early forcing is commenced, the heat should be applied very gently for the first few days, and afterwards gradually increased; 60° is ample until the buds are all nearly opened; when the leaves are expanded 65° may be the maximum, and 55° the minimum temperature (taking care at all times never to be below the minimum). When the bloom appears, 75° or 80° at midday may be the average, but with solar heat abundance of air should be allowed. To ensure a good crop, the golden rules are—plenty of heat—plenty of air—plenty of moisture—severe thinning of bunches—and severe thinning of berries. The Vine must be maintained in a healthy growing state while performing

thirty years, whereas another will be quite worn out when ten years old. Owing to the Raspberry renewing itself annually, with skilful cultivation and good soil its duration might be prolonged almost indefinitely, but such a course is neither advisable nor profitable, as Strawberries, Raspberries, and, indeed, all kinds of small fruits may be made to play an important part in a judicious rotation system of cropping. A vegetable quarter, for instance, converted into a fruit bed for a given number of years will, in due course, be available for vegetables again, the change being of benefit to both crops. The Raspberry likes a good depth of rich soil, but as this cannot always be secured within the limits of a small garden, good deep cultivation and heavy surface-mulchings afford it the greatest possible assistance, and, in very dry periods, a thorough soaking of liquid-manure is of great advantage to the crop. We generally trench ground intended for a new Raspberry plantation in September, and plant it as soon as the leaves begin to drop in rows 6 ft. apart. A single row of Strawberry plants is generally grown in the intermediate spaces during the two following years after planting as the canes are headed down pretty close, but by the end

of the second year the canes should be at least 7 ft. high, and will, if properly managed, bear a heavy crop the following summer. After that, by means of an annual heavy mulching of farmyard-manure, they should, even on light soil, bear heavy crops for eight or ten years, when it is generally advisable to have another plantation coming into bearing, as the filling-up of gaps that are sure to occur after that period is never satisfactory in its results. Few fruits are more universally appreciated, either for preserving or for culinary purposes, than Raspberries, and therefore any extra labour bestowed on their cultivation is amply repaid. Birds are their greatest enemies, and, when very numerous, I find the only remedy is to build a temporary frame-work over them, and cover them entirely with close-meshed fish-nets, for these little depredators not only eat great quantities of the fruit, but in settling on the side branches break them off continually, thus injuring the succeeding crop.

JAMES GROOM.

Henham.

MR. HIBBERD ON HARDY FRUIT CULTURE.

ACCORDING to the paper read the other evening by Mr. Shirley Hibberd, at the Society of Arts, it seems that his experiments on the cultivation of hardy fruits at Stoke Newington have been going on for the last quarter of a century. It is, therefore, to be regretted that "the light in his bushel" should have been kept so long from the pomological world; for, in this age of gigantic bunches of Grapes and of Pears each 3 lbs. in weight, what might have been effected had Mr. Hibberd's experiments been known earlier! It will be seen by his paper that his opinion of the fruit management of "practical pomologists" is decidedly unfavourable, and that they must take the Stoke Newington practice in hand for the future if they mean to succeed in supplying our markets with quantities of fine fruit. Dwarfing stocks he thoroughly condemns; nothing, indeed, but stocks strong enough to keep Apple and Pear trees growing to the size of Oak or Beech trees will satisfy him. His system of "pulley pruning" (or the willy nilly system), as applied to fruit trees by attaching pebbles to strings and fastening them to the leading branches in order to bring them nearer to mother earth to make them fruitful may be ingenious and original, but I am of opinion that a small block and tackle fastened to a peg in the ground with the string tied to the point of a branch could be gradually worked to make the branch descend low enough, and would, I believe, be an improvement on the pebble system! Mr. Hibberd promulgates in his system another original notion—that of a "reversible fruit wall," to keep the trees in shade, or expose them to sunshine in unfavourable situations, and this wall, he says, can be made with wood by any village carpenter at a comparatively trifling cost. As a practical pomologist of far greater experience than Mr. Hibberd, I am able to say that this vexed question of restriction and extension has taken up my attention for many years, and the conclusion at which I have arrived is, that much may be said both for and against restriction and extension. There is no doubt that Apples on the Paradise stock, and Pears on the Quince, are dwarfed and rendered more fruitful, and that little pruning is required, and that finer fruit is grown on them than on rampant trees. Both kinds of stock are surface rooters, and therefore on stiff tenacious soils, if top-dressed with manure or fresh soil, the roots always get the benefit of them, and fine fruit can be grown where trees on stronger stocks would fail. If Mr. Hibberd had seen, as I have seen, small cordon trees on the French Doucin stock loaded with fruit like ropes of Onions, he might have altered his opinion, for they were growing in situations where no pulley pruning could have been applied. With regard to Apples and Pears on strong-growing stocks, I believe with Mr. Hibberd that cultivators of them, who are not able to discriminate between good and bad pruning, had better let them grow unpruned as regards making them fruitful and profitable. I am afraid that Mr. Hibberd's "Reversible Fruit Walls" will, like his tiles for growing Potatoes, be only tried by enthusiasts, and that on a small scale.

WILLIAM TILLERY.

Austen's Incomparable Melon.—I am glad to see by a late article in THE GARDEN (see p. 91) that you appreciate my favourite Melon, Austen's Incomparable, which was raised here by my late gardener, George Austen, who, on the occasion of my gaining a medal for it at the Royal Botanic Society's Exhibition in 1851, sold the seed, I think, to Mr. Tiley, of Bath. It was believed to be a pure Persian, the seed of which was brought from Persia, I think, by the late Sir Brook Bridges. I write, however, now to say that I have grown it exclusively (or nearly so) for thirty years, and have it still quite pure; if, therefore, your correspondent would like

to try it again, I shall be happy to supply it. I do not know the Colston Bassett, so cannot speak of its quality.—F. PHILLIPOTS, *Porthwidden, Truro.* [I am pleased to learn the history of this Melon, and to hear that it can still be procured true. I have to thank Mr. Phillipots for the offer of seeds of it, but I have just received a packet from a friend who received it from me years ago, and who has since grown no other. It deserves all that has been said in its favour; and, in order that there may be no mistake about the true variety, I may state that the fruit is large, round, yellow, and thickly netted, and the flesh green, melting, sweet, and delicious. Mr. Phillipots would confer a boon on the public by sending it out again, for I believe it is lost to the trade.—S. W.]

The Lawrence Pear.—With regard to the Lawrence Pear, my opinion of its good qualities increases the longer I cultivate it, and I think the day is not far distant when it will be more sought after in its season than the much-vaunted William or Seckle, and I am sure that an orchard of this variety would pay handsomely. With me it does not do well as a dwarf; but as it comes into bearing the fourth or fifth year after planting, and the fruit is fully as large and good, nothing is gained by planting on the Quince stock. Like most standard Pears it does best on a gravelly loam. The good points of the Lawrence as a fruit, are good flavour, and good keeping. I have had it in eating from October 1st to January 10th, and shall have it this year until Christmas. Though not so high in favour as the Seckle, I find that I can eat more of it without cloying. It is of good size for dessert, being larger than the Seckle, but not so large and rough as the Duchess. When ripe it is of a rich yellow colour, and does not rot at the core. This Pear, described as above in an American paper, is one of those sent us in autumn by Messrs. Ellwanger and Barry; it would appear to be well worthy of trial in this country, being distinct, large, and well flavoured.

Dwarfing Stocks.—Mr. Hibberd recently said:—"As regards the Paradise stock, there are at least half a dozen distinct varieties of Apples bearing that name in cultivation, and they vary considerably in their degree of fitness for the purposes of the propagator. The one which Mr. Rivers, of Sawbridgeworth, has for many years employed in the production of miniature Apple trees is the worst of the best; and the one employed by Mr. Scott, of Crewkerne, is the best; but they are all objectionable, because less vigorous in habit than the varieties of Apples commonly grafted upon them." With reference to this statement, it is only fair to mention that the stock sent out by Mr. Rivers as the English Paradise is an excellent one, as may be seen in many gardens in every county. The essential point, however, to bear in mind, is, that there is only one true Paradise stock, and that is the stock grown for ages in France as the "Paradis." This we do not ask the reader to accept without evidence gathered in our own gardens. Mr. Barron, Superintendent of the Royal Horticultural Gardens at Chiswick, made trials of every stock he could obtain; and while all the so-called English Paradise stocks have merits more or less as regards their dwarfing tendency, the French Paradise is distinct from them all in the early bearing habit it induces in the kinds grafted on it, and in its singular and valuable habit of forming a wig of roots near the surface in wet and heavy soils, instead of running down with a tap-root as all the other stocks do.

Melons in Murcia.—The Melon grounds of Alicante, in the province of Murcia, are somewhat disappointing. Never would you believe that from those dusty, little-watered plots, would come all the wealth of succulent Melons that lie in heaps at every street corner. The Melon grounds look like an English ploughed or fallow field, with a thin carpeting of Vegetable Marrow plants. Yet, here and there, you see the great, juicy, round fruit, half covered with dust, lying on the cracking earth. All those that were ripe were gathered over night. The Melons are planted in May; in less than a month they begin to bear fruit, and keep on bearing till the commencement of October; they require less water than any of the other plants. The Melon takes, from the time that the flower falls off, to the time of plucking, about forty days to arrive at maturity. These Melons are of two kinds—first, the Melon proper, with its yellow, luscious, honeyed fruit, so well known in England; secondly, the Sandia, or Water Melon, grown on the coarsest and most sterile soil, and which is the cheapest fruit in Spain, and the salvation of the thirsty masses. The Sandia weighs from 8 lbs. to 25 lbs., and is sold at a farthing or less per lb. Its huge bulk, its hard, coarse-looking, dark green rind, the rude way in which it is kicked about, would never lead you to believe that it is so justly prized as it is. Every traveller in Spain has been offered a slice of its flesh, that looks like a crimson rock, yet melts in your mouth before you can taste its flavour. On every long, hot, dusty journey, the second-class traveller buys a huge Sandia and offers a slice to his fellow passengers; every table *à la hôte* groans beneath these crimson carys; a lamp of this cools the fevered

blood; two pounds may be eaten without fear of harm. The growth of the various kinds of melons is so much in advance of the immediate consumption, although poor and rich alike almost live upon them during two months of the year, that the gardener cuts thousands just before they arrive at maturity and hangs them up for the winter. Half or three-quarters of an acre, as nearly as I could calculate, would produce no less, in a favourable season, than 400 arrobas of melons! Each arroba weighs exactly 25 lbs. avoirdupois. Now, at a rough calculation, these 400 arrobas, weighing 10,000 lbs., may be estimated at the value of three farthings per pound, giving 30,000 farthings, which, roughly speaking, is equivalent to about £32. This calculation will give some, although but a slight idea, of the importance of the Melon trade. And, in forming his idea of the wealth of Spanish irrigated ground, let the reader remember that four crops annually are raised upon the same plot; and that growing amid Melon or Apricot grounds stand the Peach, the Fig, the Pomegranate, or the Almond tree.

Root-grafting Stone Fruits.—For the Peach, Plum, and Apricot I use the wild Plum for a stock. I take up the seedling Plums in the autumn, being careful to break off as few of the small fibrous roots as possible. I put them in a cool cellar, packed in earth, and leave them there until I wish to use them during the winter. When these roots are grafted I keep them moist, and do not expose them to cold. I use the whole root of the seedling, from 6 in. to 1 ft. long, to make one root-graft, whip-grafting near the collar. The grafted roots are then packed in earth in the cellar, to be planted out after all danger from frost is over. The success or failure depends greatly upon the amount of small roots upon the seedling stocks. Stocks that have been once transplanted are still more certain to grow when root-grafted. Last spring I did some grafting with scions and stocks which had stood out all the winter, and which had been exposed to a very low temperature; after the ground got into working order, I took up the Plum stocks, and whip-grafted them with Peach and Plum scions just cut from the trees. They were then put into the cellar until it was safe to plant them out; nearly all made a good growth, particularly the Peaches and Plums. —TILLO, WILLIAMS, Nebraska, in "Prairie Farmer."

Meloo—Gilbert's Victory of Bath.—My experience of this excellent Melon is not in accordance with that of "J. S." as I proved it to be not only one of the best flavoured and most handsome in appearance, but one of the freest setters and most productive Melons I have ever seen grown. In the spring of 1874 I visited Mr. Gilbert at Burghley, and, with his usual liberality, I received from him packets of all his favourite Melons for trial. I sowed his Victory of Bath with the others, and never was more satisfied with any Melon than this. Without removing the plants from the pots in which they were sown, I plunged them in 11-in. size, which were filled within a few inches of the top with strong loam, rammed firm with a beater. Each plant was allowed to make 6 ft. of growth before it was stopped, and the laterals showed fruit in abundance, but their numbers were reduced to six or eight to each pot, and, when ripe, the fruit averaged from 3½ lbs. to 5½ lbs. each; the flesh was of great depth, the skin exceptionally thin, and the flavour was greatly praised. When the pots were well filled with roots, a surfacing of rich manure was given, and weak guano water was administered occasionally till the fruits were fully swelled. The pots stood on the surface of the bed, which was formed of decayed leaves, the remains of the material used for forcing plants in winter. We had a supply from various kinds as late as December, but Victory of Bath was the most serviceable.—M. T.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Malta Blood Oranges Seedless.—I find on cutting open some of these delicately-flavoured Oranges that they are without seeds. I should be glad to know if a race with this peculiarity is procurable. The batch of Oranges all called Blood Oranges in which my seedless ones occurred varied a good deal, some having abundance of seeds and being without the sanguineous streaks in the flesh that we usually suppose the characteristic of the Blood Orange.—W.

Preparing for Fruit Trees (B. E. R.).—Trench the land before planting, but do not turn up the bad subsoil. With care, you may plant for some weeks to come. The maiden trees on the true French Paradise need not be more than 4 ft. apart in the line or row from row.—N.

Renovating Orchards (T).—Dig round your trees, surface-dress them with manure, scrape the branches thoroughly, and wash them with strong soap-suds or weak lye. Cultivation of the orchard with light vegetable crops in the more open spots would do no harm.—T.

The Purple Gnava (Psidium Cattleyanum).—I am surprised that this valuable addition to our choice fruits is not more extensively grown than it is. The back-wall of a Peach-house is a good place for it provided it can have full exposure to sunshine. As regards hardiness, it will succeed in a house from which frost is excluded. Give it plenty of water in summer, but keep it comparatively dry in winter; thin the shoots occasionally, and, thus treated, it will fruit in the autumn.—REX.

LARGE SEEDS BEST.

The credit of first pointing out that large seeds, other things being equal, are the best, belongs to the late Mr. Thos. Andrew Knight, and the observations of all succeeding experimentalists prove him to have been correct. There are one or two points, however, which require consideration before we can speak with confidence in the matter. For example, it is important to consider whether vegetative growth only is required, as exhibited in Cabbages, Turnips, and other vegetables, or whether flowers and fruit, or, in other words, fertility, are required in addition. So far as my experience goes, the larger and finer the seeds, and the sooner they are sown after they are ripe (where circumstances admit of this being done), the better in all cases where vegetative growth or succulent vegetables are concerned; but in the case of flowering or fruiting plants, like the Cucumber and Melon, Tomato, and others, large and newly-ripened seeds are not invariably the best, as they produce exuberant seedlings, or, in other words, vegetative growth inimical to fertility. Of this fact cultivators have long been aware; hence old Cucumber and Melon seeds have been for years preferred to new ones, or if the latter must perforce be used, it is still not uncommon to carry them in the warm waistcoat pocket for a week or two in order to weaken their vitality by evaporation, and thus obtain earlier fruiting and more fertile seedlings. This question of Luxuriant vegetative growth, as opposed to fruitfulness, should never be lost sight of, for the whole question of fruit growing or seed saving depends upon the proper balance which is maintained between these two distinct, yet inseparable conditions. In order to secure this balance we graft upon restrictive or invigorating stocks, and all kinds of fruit tree training and pruning are intended to effect the same end, the degree to which they are carried depending on soil and climate. It therefore seems that the selection of seed is not only necessary, but that the selection must be to a certain extent regulated by the kind of crop required—that is, whether fruits or seeds are wanted, or merely vegetative growth. Thick seeding is, in many cases, a mistake, for crowded seedlings enfeeble each other, and all thinned out and not replanted represent so much poor loss, and as to the thinning effected by slugs and insect-pests, they generally select the freshest and best seedlings they can find, just as wasps attack only the ripest fruit. Some few cases may exist in which thick seeding may be desirable, but as a rule thin seeding gives better results. The selection of the largest seeds of any given kind is most readily effected by using carefully made sieves or screens, and in this manner selection is now largely practised by our principal seedsmen, although not to that extent which modern experimentalists deem desirable. B.

Lilies in Pots.—I have been induced, through reading Mr. Baines's note on this subject (see p. 152) to send you a notion on the cultivation of Lilies both in the open ground and in pots, which I think will prove valuable. It is well known that good fibrous peat has considerable antiseptic power, and that the roots of many Lilies like rather more generous soil than peat is shown by the strong vigorous roots which we often see clinging to a small piece of loam. I believe that it will be found, if the two kinds of soil be placed in layers, both the preservative power of the peat and the good feeding power of the loam may be obtained. I have tried largely this season, both in new beds and in pots, placing at the bottom a good stratum of a mixture of loam, sand, and peat, then a thin layer of pure peat, then the bulbs, covering them with peat, then a good top layer of the loam, sand, and peat mixture, for the benefit of the roots from the top of the bulb.—GEORGE F. WILSON, Heatherbank, Weybridge.

Epiphyllums as Wall Plants.—These lovely autumn and winter-blooming plants require an elevated position in order to see them to advantage; they therefore look well on back walls of forcing-houses, on rafters, and in similar positions. They will succeed under a wide range of temperature, and are not at all particular as to soil. The system adopted here is to plant the Pereskia stocks in any position that it is thought desirable to ornament, and to train up shoots about 2 ft. apart, or single ones if amongst scellaneous creepers or on rafters, and allow them to run to the top of the house before stopping; they quickly attain the necessary length, and about this time of year we insert on their stems grafts of Epiphyllums 1 ft. apart during their whole length, changing the varieties according to taste. Under the influence of a high moist temperature they make rapid growth, and will each produce the first year several heads of bloom; by the end of the second year they will be perfect columns of luxuriant leafage, and during the duldest months of the year each shoot will furnish an abundance of blossom; when planted out, they are not subject to that trying ordeal known as "drying off," and consequently their luxuriance astonishes even those who are well acquainted with their cultivation.—J. GROOM, Henham.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Eucharis amazonica.—This is one of the best of all stove plants for general decorative purposes or for furnishing cut flowers, blooming, with simple treatment, two or three times in the year at no particular season; and it can be regulated as required by alternate growth and rest, and will flower in either a small or large state, big plants of course producing the most blooms; but, for ordinary purposes, a medium size, say, grown in 10 or 12 in. pots, is the best, especially where space is limited. Amateurs possessing half-a-dozen plants of the above size will, by exercising a little forethought, secure a long succession of flowers. After resting, by withholding water partially for six or eight weeks, a couple of the plants at a time should be placed at the warmest end of the stove and be well supplied with moisture; this will quickly cause them to throw up their bloom-stems, when the flowers—of which there are several to each umbel when the plants get strong—will open in succession; and, when wanted for cutting, can be removed as needed. Well-established specimens will keep pushing up a succession of flower-spikes for several weeks, at the same time making fresh leaves and bulbs, which must be encouraged with plenty of water and heat (say 60° in the night and a few degrees more during the day) to complete their growth, which, when fully matured, must be gradually subjected to the drying process, and again rested, others, in the meantime, being induced to flower so as to succeed the first, and so on throughout the year. This *Eucharis* is one of the most accommodating of plants, and can, by being treated as above, be got to bloom at any time either during summer or winter. There are one or two things to be observed in its management; it must not be forced into rest when the growth is incomplete, that is, before the leaves have attained their full size; water must be withheld, so as to stop growth, but the soil must not be allowed to remain completely dry so as to kill the leaves, giving a little when the plants flag; neither must they ever be subjected to too low a temperature, even when at rest, especially in the winter, as rest can be induced by letting the soil become dry; heat being beneficial in ripening the bulbs, they should not be kept for any length of time in a lower temperature than that of 50°.

Other Indoor Plants.—*Euphorbia jacquiniiflora* is one of the very best plants that amateurs who have the convenience of a stove can grow; not only is it easily managed, but it possesses the advantage of blooming in small pots, of about 7 in. or 8 in. in diameter. Its season of flowering can be prolonged for several months by growing a sufficient number of plants, and bringing them on in succession; after the first sprays of bloom have been produced from the leading part of the shoots, if this portion be cut off and the plants kept in a brisk heat—60° or 65° during night—they will push a second growth from the latent eyes, which will flower almost as well as the leading portions of the shoots. As I have before pointed out, to have the flowers of this and all other winter-blooming subjects that require stove-heat to bring them out in the best condition as to brilliancy of colour, and also to produce them with sufficient substance to stand long without flagging when cut, they must be placed whilst the flowers are coming on as much under the influence of full light as possible. In the matter of light to winter-flowering plants, there is frequently a want of conception, many supposing that if a plant stands in a light house with its top within two or three feet of the glass this is sufficient to give to the flowers their wanted properties. This can best be understood by relating my own practice with the description of subjects under consideration. I place the plants on a shelf on a level with the bottom of the front upright lights, about 2 ft. from the roof; if the shelf be further from the roof than this, elevate them on inverted pots. I then take some thin string and fasten it with tacks across the underside of the sash-bars of the roof-lights; the strings, thus running lengthways of the house over the path, are placed about 6 in. apart; such plants as this *Euphorbia*, *Plumbago rosea*, slender-growing *Begonias*, and any subjects with straggling pliable shoots are arranged with their branches up against the strings, and kept in their places by strings run underneath them. The object of the first course of strings is to keep the shoots from absolutely touching the glass, the moisture upon which would rot both leaves and bloom. The difference in the intensity of colour and substance in the flowers so produced, as compared with those borne by plants that are arranged in the usual way in a stove during the short days of winter and early spring, can only be realised by those who have tried both methods. One great advantage is that when flowers are grown under conditions that enable them to last long, especially when cut, fewer plants are needed to produce the requisite quantity. The demand for cut flowers at the present day is such as to require through the winter season close attention in learning the best means of producing them; this can only be arrived at by trying different methods with

different plants. Too high a temperature that induces quick development is not generally conducive to the flowers lasting long; but any attempt to bring plants into bloom with considerably less than the requisite amount of heat usually ends in failure; yet there are some exceptions—the brilliant *Poinsettia pulcherrima* requires a brisk heat to bring its flaming bracts up to their full size, but if a portion of the plants be placed about Christmas in a house or pit where a temperature of 50° in the night can be kept up, with 5° more during the day, they will flower and produce their bracts about half the usual size; but thus grown they will last upon the plants for eight weeks most intense in colour; the heads in this size are more useful for cutting than when larger, and the individual bracts, when used for bouquets, are much better than those produced in more heat. When all the above plants have ceased flowering they should be placed at the coolest end of the stove, and have just as much water given them as will keep the soil from getting quite dry; do not head them down till later on, when they will receive more heat to start them into fresh growth. The varieties of *Centradenia*, *C. rosea*, and *C. floribunda*, are small-growing plants, very suitable for amateurs either in large or small houses; their flowers will last for a considerable time either on the plants or when cut; they are easily grown in a temperature of 55° or 60° through the winter.

Hot-beds.—Fermenting manure, as prepared for a Cucumber bed, should by this time be in condition for use; where no regular frame-ground exists, a place should be chosen fully open to the south, so as to receive all the light possible, but sheltered from the north and east winds, as upon this will depend the length of time that sufficient heat can be kept up without the trouble of applying fresh manure to the sides of the bed. At this early season it should be made 3 ft. longer, and as much wider than the frame which is to be placed upon it, and ought not to be less than 4 ft. 6 in. in depth when finished, as it will settle to half the height when made up. Put on the frame, at once, and raise the lights at the back an inch or two to allow the steam to pass off, thrusting a stout stick in the centre to test the heat afterwards before the soil is put on. It is better not to make up the first bed larger than will do for a single-light frame, making another larger later on wherein to grow the plants, merely using this for bringing them forward until fit to plant out. Although it is always advisable to make the first bed sufficiently early to get these and many other seeds that may be raised in it as advanced as circumstances will permit, yet I should recommend amateurs who have not at command a sufficiency of hot stable manure alone, or plenty of leaves to mix with it, so as to keep the heat up in a way that will prevent the plants being checked in any way, to defer hot-bed making for a few weeks later, as disappointment is sure to follow when early made hot-beds cannot be kept up to the required temperature. Much slighter beds will do for Potatoes, Radishes, and Carrots, as there is nothing gained by putting together a larger body of fermenting material than is necessary to start these fairly into growth; if the beds be 2½ ft. high and 8 or 10 in. wider all round than the frame, they will be sufficiently large.

Early Peas.—As soon as the first-sown Peas make their appearance, another sowing should be made, putting in some of a similarly early sort to those first sown, as also a sowing of second early, such as *Champion* of England or *Cullingford's Champion*; if all these be sown at the same time, a succession will be ensured. In cold backward soil, where it is found necessary to make the first sowings of Peas in frames, vineries, or any cool house in which room can be spared, with many amateurs the strips of turf usually used for sowing them in are not to be obtained. In this case they may be sown in propagating boxes, putting them in thickly, say not more than ½ in. apart, and covering them with an inch of soil; they will soon vegetate. When they have got 4 or 5 in. high, they should be removed to the south side of a wall to ensure them to the open air, after which they can be moved from the boxes with as little mutilation of the roots as possible, and planted in rows in a sheltered sunny border. In sowing Peas in this way, the soil should be of a loose nature, such as old potting soil, or such as was used for Cucumber or Melon beds last season, to which may be added some leaf-mould, as, if put in adhesive heavy material, the roots will be much broken in moving them from the boxes.

Radishes and Mustard.—When the first crop of Radishes lately recommended to be sown in the open ground is up, the litter should be drawn off them daily, when the weather is mild; if they be attacked by slugs, strew a little soot and lime mixture over them. The birds are sometimes very troublesome when they first appear; a few lengths of white thread strung across the beds, about 9 in. from the ground, will be found sufficient to deter them. Another sowing of Radishes should be made, which should also be covered with litter. Some Mustard should also be sown under a south wall protecting it with a mat.

Forcing Houses.

Continue to introduce into these a few plants of a hardy nature, such as Rhododendrons, Azaleas, Dentzias, Lilacs, Weigelas, Sweetbriar, and plants of that class, according to requirements. Where plants are in much request for decorative purposes in large conservatories, halls, &c., a few of the above, associated with large Palms, Ferns or fine foliated plants, make bold, effective groups, and may be used in place of others of far more value. Both Rhododendrons and Azaleas succeed almost equally well (when dug up and potted for forcing at once) with others that have been grown and established for years; therefore, any one having plants well set with buds that are now standing in beds or borders from which they can be spared, need have no hesitation in taking them up, as they always lift with well-matted balls. These may be considerably reduced to suit the size of the pot it may be thought desirable to place them in, as their powers of rapid root-formation are so great when placed under favourable conditions, such as the warm humid air of a forcing-house, that they scarcely feel the removal, but expand their flowers as freely as if they had never been disturbed. Small as the ball may be that is left on them, it is sure to contain an immense number of the most minute roots, that are soon in an active state after the plant is once placed in heat. Where such as these are used, well ply the syringe over them, so as to keep their leaves constantly moist, and water freely at the roots to encourage a fresh set of feeders before the flowers expand, or they may at times flag for want of support if dry, sunny weather prevail when the plants are in bloom. Keep such as Eupatoriums and *Spiraea japonica* well saturated with water, as they will take any quantity, and improve in size and healthy appearance, according to its use. Any of the latter, Lily of the Valley, or indeed all plants that have been forced, should when out of bloom be returned to the shelter of some warm house or pit, where they may continue their growth unchecked. This is the time of all others when plants require the greatest amount of attention, as the tender growth made in the close confined air of a forcing-house is sure to be thin and delicate, and therefore easily susceptible of injury. If flowers be expected from the plants next season the foundation must now be laid, and the only way of doing this is to place them where they can have the benefit of a little heat and moisture to keep them moving slowly on. All bulbs of Hyacinths, Tulips, Narcissus, &c., intended for late blooming that are now under ashes, should be got out at once, before growth becomes further advanced, or they will materially suffer; place them in close moist frames, so as to obviate the necessity of watering, and keep a mat over them for a few days, as a too sudden exposure to light would be sure to affect the blanched leaves unfavourably. The mild humid atmosphere of the forcing-

house, or other similar position, should now be made use of to forward a few plants of *Humex elegans*, as they are sure to come in usefully for single vases in both the conservatory and flower garden during the summer months. When clothed with healthy foliage down to the pot, and carrying large heads of their graceful, feathery, reddish-brown plumes, they are exceedingly effective in either of the above positions. A good stiff loam, with one-third of thoroughly decomposed vegetable matter, such as leaf-soil, is the most suited to their requirements; pot firmly, and give plenty of water as soon as the roots reach the sides of the pots. If allowed to suffer at any time from want of this, they are sure to lose their under leaves and present a shabby appearance. Keep the temperatures of the above structures as uniform as possible, always dispensing with fire-heat during the day whenever it can be done, as the sun will be found to do its work in a far more satisfactory manner. Very little, if any, air beyond what finds its way through the laps will be needed till the sun has much more power, and raises the temperature higher than is considered necessary or desirable for the well-being of the occupants. As plants begin to expand their flowers, elevate the heads so as to bring them up as near to the glass as possible, that the flowers may be improved both in colour and texture. In some cases it maybe desirable to remove them to more airy and less humid structures to open their bloom, and any little extra labour in this direction is sure to be repaid by the increased time they will last.

View in the Hilly Country of Quiballa, Angola—*Camöensis maxima* (see p. 177).

Stove Ferns.

These will now be pushing up their young fronds, and therefore no time must be lost in re-potting such as require it. The soil for this purpose should have been got under cover as previously suggested, and where this has been done it will now be in a proper state for use. If, from unavoidable causes, it still remains stacked and exposed to the outer air, a sufficient supply for each day's use should be got into the Fern-house overnight, and this will admit of the plants being potted without taking them out and subjecting them

to the chilling air of an ordinary potting-shed. Where this is unavoidable, a few only should be taken out at a time, that they may be returned again as quickly as possible. As the different varieties do not all succeed equally well in the same kind of soil, it will greatly facilitate operations, where there are many to be potted, if those that prefer a soil consisting principally of peat be taken in hand first, or *vice versa*. The strong growers require a much larger proportion of loam, so that both cannot well be treated at the same time without a constant mixing of soils. As most Ferns improve by abundant supplies of water when growing freely, the pots should be well drained that it may pass readily through, or the soil will soon become close and sour, ending in the destruction of all delicate feeding roots, if not of the plant itself. Avoid over-potting, as that is a source of much

mischievous where the watering is in the hands of those unskilled in plant culture, or who pour it into the pots without examining whether the plants are in a fit state to receive it or really require it. Much injury is done in this way, especially during the winter months, and nine-tenths of the failures in the raising of plants that occur may be traced to this cause. This is not so much the case, perhaps, among Ferns, as they do not suffer so readily in this way as most other plants, but even to keep them in a healthy vigorous state there are times when the utmost care should be exercised in giving them water; as, for instance, immediately after potting, and during the autumn and winter when growth is less active or has nearly ceased altogether. At such times very little water is requisite, and if given at all freely, injurious results must follow. With plants fresh potted, be they Ferns or any other, if water be given too liberally before the roots get full possession of the new soil, it will become sodden, in which state few plants make use of it. In potting Ferns, let the soil be as rough as possible, that it may lie free and open, a condition in which most of them delight in; for *Gleichenias*, *Phlebodiums*, *Goniophlebium*, *Davallias*, and others of that class that have their rhizomes scarcely buried beneath the soil, or send them clinging over the rims of the pots or pans in which they are growing, can seldom be turned out without breaking or injuring a number of them; and it therefore becomes necessary either to destroy the pots or to transfer them to others with the old one entire, the latter, in some cases, being the most preferable. Fresh sweet soil, in however small quantities, has a most beneficial effect on the health and vigour of most Ferns, and where it is not thought desirable to shift into larger pots, a good top-dressing of rough loam and peat may be advantageously employed; or, better still, in the case of such as have small fibrous roots so as to admit of the ball being reduced, shake off a portion and re-pot in the same-sized pots, as it often occurs that these must be limited, to render the Ferns suitable for particular purposes. Advantage should be taken while the stool is going through hand to divide such as it is thought desirable to increase. Most Ferns readily admit of this being done, and the best way to effect it is to cut the ball completely through, using for the purpose a large sharp knife or other suitable instrument. When potted, give a good watering to settle the soil, and keep the house well charged with atmospheric moisture. To effect this, syringe the floor of the house, the stage among the pots, the walls, and all available surfaces. On the afternoons of fine sunny days, give a gentle bedewing overhead, and keep the house close till they start freely.—J. SHEPPARD, *Woolverstone Park*.

Indoor Fruit Department.

Peaches.—In the early house the fruit will now be set, and where it is thick it should be partially thinned out at once, leaving more than enough for a crop until the stoning process is over. Rub off all back and front shoots, and disbud where the young wood is too thick. Admit air on all favourable occasions, but avoid having front and top air on at one time, so as to cause a draught. Shut up as much sun-heat in the afternoon as possible. Use the syringe freely night and morning, and maintain a night temperature varying from 55° to 60°, with sufficient front air to keep up an equable atmosphere, and prevent red spider. Never allow the border to get dry, and ascertain that it is watered to the bottom, for Peaches and Nectarines are impatient of drought. Should green fly make its appearance fumigate with tobacco smoke on two successive nights. For trees in flower the atmosphere should be kept drier at night, and the temperature at about 55°. Assist the setting in the middle of the day by means of a camel's hair brush. Avoid currents of air, but keep up a gentle circulation in the atmosphere, which should be dry. All late houses should now be get ready for starting; avoid laying in too much wood, the results of over-crowding being weak, watery shoots, that generally drop their buds the following year. Top-dress, and if dry, water, keeping the house perfectly cool until a start is to be made.

Figs.—Attend strictly to pinching as before recommended; keep the plants in good shape. Maintain a night temperature of from 55° to 60°, and water with manure-water every time water is needed; for, being gross feeders if profusely drained, they will be benefited thereby; syringe freely morning and night, but, where the fruit shows signs of splitting, gradually withhold water; shut up as early as the sun-heat will allow, with an agreeable humid atmosphere. Figs may be readily grafted or budded in the same way as the Vine, and as soon as a few leaves have been made is a good time to perform the operation.

Strawberries.—Those that have set their fruit may be forced sharply by day, but the night temperature should not be above 60°; water with manure-water, and they must never be allowed to become dry. High flavour and colour are unobtainable by hard forcing;

bring forward successional batches in a temperature of from 45° to 50°, and keep down green fly by means of tobacco smoke before the plants come into flower.—J. HUNTER.

Hardy Fruit.

The recent cold weather has given a beneficial check to vegetation, there having been no perceptible difference in the growth of fruit-buds for more than a fortnight. Appearances are now in favour of a late blossoming period, a circumstance much to be desired, for, if the fckleness of our spring season be taken into account, the later the trees can be made to blossom the greater are the chances of a full crop of fruit; so convinced am I of this that at this season, and onwards till the buds begin to burst, we here let down the wall-coverings to shade the trees whenever the sun shines, and the results have been such as to justify me in recommending the practice to others. In our uncertain climate protection of some kind or other for Apricots and Peaches is imperatively necessary, and where proper appliances in the shape of curtains of canvas, frigi-domo, and hexagon netting do not exist, a temporary covering can be made by placing poles in a sloping form against the walls, and fastening netting to them two or three ply-thick, straw or hay-bands, evergreen branches, or thick twigg branches of Birch; where large branches of the latter can be had, poles will be unnecessary, as the thick end of the branch can be fastened in the soil, and the spray may be allowed to rest lightly against the trees. This is a simple and expeditious mode of protection, and very effective. It is of the greatest importance, both for the welfare of the trees and for keeping pace with the work, that all pruning and nailing be completed early; and, if through unavoidable circumstances, either of these operations must be left till late in the season, let it be in reference to trees on north walls, such as Plums, Currants, and Morello Cherries; and when pruning the latter keep in view the fact, that the fruit is mainly produced from the wood of the past season's growth, consequently the system to adopt in pruning is, first to thin out all weak or unripe shoots; and next, till the trees are sufficiently thin, those most bare of buds, which will generally be wood that has borne most fruit the previous season. Raspberries must now be pruned and thinned out, for if left longer, injury will be the result. There are many modes of training them, but the best is a strained wire fence, about 4 ft. in height, to which the canes should be trained, in a slanting manner, 6 to 9 in. from each other. The Raspberry, being a gross feeder, requires a large amount of manure, which should be applied in the form of surface-mulchings, and not dug in. Autumn-fruiting sorts should now be cut right down, and, as new canes are formed, thin out the smallest, leaving four or five of the strongest to each stool. Where new plantations are to be made, select for them the wettest part of the garden, and if partially shaded from the sun, so much the better, for they delight in a cool position, and are most impatient of drought.—W. WILDSMITH, *Heckfield*.

Trees and Shrubs.

In the nursery the filling up of vacant quarters with deciduous trees and shrubs should be pushed on whenever the weather is favourable for such work. The planting of tree and shrub cuttings and the sowing of forest tree seed (with the exception of that of Conifers), if not already done, should not be deferred much longer. During frosty weather cart or wheel manure or compost on to bare ground where required, and the annual stock of leaves and turf should be conveyed to the nursery and stacked. Ornamental planting in progress must now receive attention, particularly the planting of deciduous shrubs and trees and Pampas Grass. *Rhododendrons* should also be planted now in order to ensure their blooming well the first season, but the planting of other evergreens may be put off till later in spring, so as to afford opportunity to get on with the planting of deciduous trees and shrubs, as late planting, in this case, tends to check growth during the incoming season.—G. BERRY.

Pitman's Sun-dial.—Old Mills, the optician at Milwankie, sold a sun-dial to Pitman, a short time ago, with the assurance that it was a first-rate timekeeper. About a fortnight afterwards Pitman called at the shop and said, "Say Mills, that sun-dial ain't worth a cent; it's no good as a time-piece anyway." "Did you ever time it by your watch?" "Certainly I did. I've stood close to it often exactly at the even hours, and the blessed thing has never struck the time once." "Impossible! Why, you did not expect it to strike the hours, did you? It don't strike, of course; it has no works inside." "That's what puzzles me," said Pitman. "If it ain't got no insides, hows it going to go?" "Mr. Pitman, where have you placed that sun-dial—in the garden?" "Garden! My gracious, no! I what do I want with a timepiece in the garden? It's hung in the settin'-room agin the wall."

THE KITCHEN GARDEN.

THE GREAT AMERICAN POTATO COMPETITION.

DR. F. M. HEXAMER, of the Committee for awarding the £100 premiums offered by Messrs. Bliss to growers of the largest quantity of Snowflake and Eureka Potatoes from 1 lb. of seed, has prepared an interesting and valuable report. It will be remembered that the conditions for competitors required a sworn statement of date of digging, with a written memorandum of mode of culture, characteristics of soil—whether clay, alluvial, sandy, or loam—nature of subsoil, whether under-drained or not; also, the kind and quantity of fertilisers used, how and when applied, with the weight of the product when dug and the number of square feet occupied by the crop. Growers were placed under no restrictions as to their mode of culture, excepting that the Potatoes must not be raised from slips or forced by artificial heat, the object being to ascertain their respective merits with such culture as is usually given to crops in a well-managed vegetable garden or farm. The award of prizes was as follows:

For the Largest Quantity of Snowflake from 1 lb. of Seed.

	lbs.
First prize to P. C. Wood, Esther, Ill.	1347
Second to J. L. Perkins, Little Sioux, Iowa	1304
Third to Frederick H. Seiler, Verona, Essex Co., N. J.	1123
Fourth to J. I. Salter, St. Cloud, Minn.	1090½
Fifth to Alfred Rose, Penn Yan, N. Y.	1082½
Sixth to Henry V. Rose, Penn Yan, N. Y.	1069½

For the Largest Quantity of Eureka from 1 lb. of Seed.

	lbs.
First prize to J. L. Perkins, Little Sioux, Iowa	1666½
Second to P. C. Wood, Esther, Ill.	1403
Third to Alfred Rose, Penn Yan, N. Y.	1149
Fourth to Milton M. Rose, Penn Yan, N. Y.	1145
Fifth to J. I. Salter, St. Cloud, Minn.	1087
Sixth to Henry V. Rose, Penn Yan, N. Y.	1066½

When two years ago your Committee awarded the first prize for the largest yield of Extra Early Vermont Potatoes from 1 lb. of seed to Mr. Salter of Minnesota, for the then unprecedented yield of 607 lbs., many considered the climax of productiveness reached, and not a few doubted that such a quantity had ever been grown from so small a quantity of seed. Yet so much has the general interest and ambition stimulated the cultivators of the soil, both here and in Europe, that in England nearly double that amount (1082 lbs.) has been grown from 1 lb., and in our own country no less a yield than nearly treble that obtained then entitles now to a first premium, and nothing less than 1000 lbs. from 1 lb. can win even the lowest premium. These marvellous results will naturally cause, with many, suspicions about the correctness and truth of their statements; yet no one who has carefully examined the reports and affidavits, and has read the many letters received from disinterested parties, all of which vouch for the reliability of the successful competitors, can doubt the veracity of their reports. We have given above the full address of every successful competitor, so that anyone may satisfy himself about the standing of these gentlemen, and if any false statement should have been made, we would be glad to ascertain the fact, that such parties may be exposed, and excluded from competing for premiums to be offered hereafter. Ten barrels of Potatoes from 1 lb of seed! What next? It is easy to calculate: fifteen, twenty and forty barrels! There is not one competitor who does not know that he could have done better, and that he will do so next time; that if every one of his hills had yielded like the best ones, and in a more favourable season, his yield would have been much larger, and that if two hills may be made to yield 56 lbs., more can be made to yield a like and even larger amount, which would, in this case, have given 6850 lbs., or over forty-one barrels. Mr. Perkins's soil was "a mixture of sand and clay, very rich in vegetable matter to the depth of 18 ft., and underlying this is a gravelly subsoil. For three years the ground was used as a stock-yard the straw being left on the ground to rot and be burned." Another competitor describes his soil as "black loam, 4 ft. deep, on the bank of a creek, and it has been used as a cattle-yard for ten years." Another, "as vegetable mould and sandy loam, 3 ft. deep, never cultivated before." Many describe

their soil as "deep, very rich, the best Potato soil in the State."

The fertilisers used comprise nearly every known manure, and the quantities applied are not less enormous than the crops raised with them. Most growers have made compounds of various materials, and some seem to have faith in complicated formulas, which they prepare with the accuracy of a physician's prescription. About the value of wood ashes, poultry manure, and plaster, however, there seems to be no doubt, and we find them used by a large majority. Sulphur has been used by many. This substance does not enter into the composition of the Potato, and it would be interesting to know if its application actually increases the yield. Have experiments to this effect been made?

The fact that single eyes and eyelets will, with good care, produce large crops, has been sufficiently proved. All the large yields were grown from very small sets. In some cases, single eyes were divided into ten pieces, and in one instance 240 sets were made from 1 lb., nearly all of which grew well. The sets, with few exceptions, were planted singly, yet we find a product of 970 lbs. raised from fifty-two hills, two sets to each, nearly 19 lbs. per hill, and 677 bushels per acre. Whether this large yield is due only to the very favourable soil they grew in (a rich black loam, formerly used as a stock-yard), and the immense quantities of ashes applied in the hills and as top-dressing (one peck to the hill), or to the two-set system, does not appear. It is to be regretted that a part of the plot was not planted with one set to the hill, and the products weighed separately. The planting in nearly all cases was done between the 10th and 26th of May, and one-fourth of all competitors dropped the seed on the 10th of May, nearly a week earlier than in former years. A comparison of the distances between the hills with the average yield per acre gives a most interesting and valuable Table as follows:—The sets planted at a distance of

2	by	3	ft.	gave	a	yield	of	378	bushels	per	acre.
3	"	4	"	gave	a	yield	of	462	bushels	per	acre.
3	"	3	"	gave	a	yield	of	651	bushels	per	acre.
3	"	3½	"	gave	a	yield	of	441	bushels	per	acre.
3	"	4	"	gave	a	yield	of	372	bushels	per	acre.
3½	"	4	"	gave	a	yield	of	342	bushels	per	acre.
4	"	4	"	gave	a	yield	of	332	bushels	per	acre.
4	"	8	"	gave	a	yield	of	88	bushels	per	acre.

The large number of data, of which the above figures form an average, give these statistics a special value. It will be seen that although the greatest yields from 1 lb. grew from hills 4 ft. apart, the largest crops per acre were raised at distances of 3 ft. each way, and that as the distances between the hills are increased or decreased, the yield diminishes in regular proportion. In the first case, there remains wasted ground which is not reached by the roots of the plants; and in the latter, the roots are so crowded that they cannot obtain all the nourishment they are capable of consuming. The mode of planting and cultivating with a large number of best cultivators, consists in crossing their fields with furrows 6 or more in. deep. The sets are dropped at the crossings and immediately covered with about 2 in. of soil or compost. The haulms as they grow are hilled up gradually, and frequently to a final height of 12 to 18 in.; then large, broad hills are made, using all the soil between the rows.

A considerable space in the reports, enough to fill a good-sized volume, is taken up with descriptions and praises of the new varieties. The Snowflake has received more and higher praise than has probably ever been bestowed upon any Potato. There is no dissenting voice among the whole list of reports, nearly everyone of which contain, "It is the best Potato I ever saw." Its quality and uniformity of size are especially commented upon. In many cases twenty-five to forty perfect Potatoes were found in every hill planted, and tubers of 2 and 3 lbs. each cooked readily and completely through. Mr. Perkins could select 1000 tubers weighing 1000 lbs. from a gross product of 1304 lbs., and finds them preferable to any Potato out of over 100 varieties he grew. Mr. Salter "never saw so fine a Potato; beautiful in colour and shape, firm in texture, flesh white; luscious cooked in any way; it stands unrivalled." There is certainly within our knowledge no variety which combines all the essential points of a Potato in as high a degree as the Snowflake. Quality, shape, size, colour, yield,

are all that can be desired, and it is difficult to preceive in what direction further improvement can be obtained.

The Eureka, having had nearly as extensive a trial as the Snowflake, has likewise received many favourable notices. Some growers value it as much even as the preceding. Its main value, however, seems to consist in its immense productiveness. Two hills yielded 56 lbs. in one case, and in another instance 970 lbs. grew from fifty-two hills, being an average of nearly 19 lbs. per hill and 677 bushels per acre. There are cases reported where three tubers from one hill weighed 9 lbs.; and one grower reports one single tuber weighing 5 lbs.

Yet like those excellent old varieties, the Pinkeyed, Kidney, Mercer, and others, which have deteriorated and passed away, so will these now uncelebrated favourites have their day and will be heard of no more. Therefore, do not pause in your good work, Messrs. Pringle, Brownell, Compton, Breesee and other raisers who believe in perpetual progress! We can never know how much we may accomplish as long as we continue our labours. There has been gradual increase of vigour, combined with good quality, in many of the new seedlings raised since the time of the Rev. Mr. Goodrich. The Snowflake and Eureka have been grown alongside of some older sorts, and it has been found that the new varieties will stand almost any amount of manuring and return a corresponding yield of tubers, while the older sorts under the same treatment would make nothing but haulm and a few small tubers.

EARLY VEGETABLES.

We are all apt to attach an imaginary value to any crops that can be got early; therefore anything that tends to hasten the maturity of our earliest crops of vegetables is a great desideratum. Even with a large amount of glass in the shape of pits and frames for forcing early vegetables, it is desirable to take advantage of the most sheltered positions in the open air for forwarding a small planting of the vegetables in greatest request, so that there should be no blank between the forced products and those of the main crops. For this purpose there is nothing more serviceable than borders in front of walls with a south aspect, such as are usually devoted to Peaches, Apricots, &c. I find the best results are obtained with borders of medium width of about 10 or 12 ft., with a sharp incline from the wall, to catch every ray of sunshine, as it is by economising both those that fall on the border and those that are reflected from the wall, that the crop is enabled to arrive at its earliest maturity. Few vegetables are more universally prized for their earliness than Peas, and by planting the rows at wide intervals, so as to admit of intermediate cropping, and by thickly staking the rows and adding evergreen branches as an outer protection, they form excellent screens for breaking the wind, which is even more disastrous to early crops than frost, or rather the effects of the latter are more easily guarded against by temporary coverings at night. Early Cabbages should also always be accommodated, for in March and April they are highly appreciated as a first-class vegetable, but where plentiful in open quarters are looked on but indifferently by kitchen authorities; next should follow the earliest Ashleaf Kidney Potatoes to succeed those in pits;

Cauliflowers protected by hand-lights or cloches, and gradually hardened off; Early French Horn Carrots are always in demand; and very useful will be found a small sowing of Early Dutch Turnip, any early dwarf variety of the Broad Bean, and French Bean. Salads should have at all times great care, and a row of Cabbage or Brown Cos Lettuce planted close under the wall in autumn comes in very early and acceptable. A portion should also be devoted to the earliest sorts of Strawberries. The quantity of each need not be large, as the main crops advance rapidly as the temperature increases, and last longer in perfection on cooler ground; but the advantage of a fortnight's supply gained on the main crops is sometimes of great importance. As the early crops are cleared off, the borders should be heavily mulched and watered to assist the ripening crops, and the succeeding autumn crops generally consist of late French Beans, Cauliflowers, and salads. Brown Cos and Cabbage Lettuce, Green Curled and Batavian Endive, if covered with Fern fronds, may be had in perfection the whole winter. JAMES GROOM.

GOOD VARIETIES OF SWEET CORN.

We need not consume time or space in speaking of the value of good Sweet Corn, nor of its culture. A few remarks about varieties are all that will be necessary. The earliest good Sweet Corn with which we are acquainted is the Minnesota (fig. 1); following in about ten or twelve days, is Russell's Prolific (fig. 2); Moore's Early Concord (fig. 3) is in use a week or so after Russell's; and Crosby's Early (fig. 4) is in use about the same time, perhaps a day or two earlier: it is very thick, 12 or 16-rowed. Stowell's Evergreen (fig. 5) is a magnificent late variety, keeping in use almost until winter. There are many varieties of Parching Corn; one of them is shown in fig. 6, called the White Parching.—

JAMES VICK. [Some of these varieties would seem to be well worth a trial with us, particularly numbers 1 and 2. It is well to bear in mind that, to enjoy "Sweet Corn," it is not necessary to ripen it. The grains are consumed in their green and tender stage, as young Peas are. Therefore, over a large portion of the country, "Green Corn" could be enjoyed, and there are few vegetables so good.]

HEELING-IN BROCCOLI.

I CANNOT consistently allow some remarks on this subject in THE GARDEN (see p. 124) to pass unnoticed. It is there assumed that the immunity from frost enjoyed by market garden and field crops of Broccoli over those grown in confined gardens arises from the greater amount of air to which the former are subjected, but this is not wholly in accordance with fact; on the contrary, the immunity in question is rather due to the difference in culture. In private gardens it is the rule to move the soil to a great depth and manure heavily; this induces rank growth, and the stems of the Broccoli, instead of consisting of tough woody fibre, have a great proportion of soft pith, and in very severe weather soon succumb to frost. The check obtained by heeling-in comes too late, as it is not done until hard weather is close at hand, and all my experience goes to prove that plants that have their roots disturbed then are much less capable of withstanding frost than if left with their roots intact and well established. For heeling-in in close confined gardens to be of

The best varieties of Sweet Corn.

any real value, it should be done at the end of August, and then the plants would have plenty of time to obtain a fresh root-hold ere the winter became severe. Still I have doubts as to the utility of the process; growers for market seldom move their soil below 12 in., and often less; although they manure very freely, their plants do not strike root deeply, but large numbers of small fibrous roots are secured which promote a vigorous and solid growth and a hard stem. Market growers also roll their ground firmly before planting; indeed, as a rule, Broccoli prefers soil much harder than it usually gets in confined gardens. A. D.

As in our own columns, writers to the "Gardener's Magazine" vigorously defend heeling-in Broccoli. Mr. Cocks says:—"I am surprised to see the good old practice of heeling in or laying down Broccoli so strongly written down. I have followed the practice for a number of years, and followed in the footsteps of some good old practical gardeners, and can say with confidence I have always found very great advantage by it, especially so with the tall varieties, such as Sutton's Perfection, Veitch's Spring White, the last-named being the most valuable of all I grow for spring use. I have some of the dwarfier kinds—Miller's Dwarf, Backhouse's & Snow's Winter White—not heeled in. After the last fall of snow they looked beautiful; but, as the leaves drooped with the weight of snow, many broke off, exposing the most tender parts of the plants to 18° of frost, which we have had here." Another correspondent says:—"After many years' experience I am satisfied that Broccoli carefully heeled over will endure unharmed 10° to 15° of frost more than those standing upright. If the writer who condemns the practice intends to say that Broccoli so treated produces smaller heads than those left untouched, then I can agree with him; but I would ask, Are not small heads better than none at all?"

POTATO CULTURE IN SMALL GARDENS.

AFTER the exhaustive reports on Potatoes which we have had, it may be superfluous to say more on the subject; but, although we are now in possession of some valuable facts as to the disease which so seriously affects our crops, we unfortunately cannot yet congratulate ourselves on possessing anything like a specific remedy; anything, therefore, likely even to abate the virulence of the disease may be acceptable to many, as, notwithstanding its attendant drawbacks, the Potato is still the staple crop in garden allotments; and in this neighbourhood there are few labourers who cannot dispose of a sack or two of Potatoes even after providing for home consumption. East Anglia may perhaps enjoy some immunity from disease, its atmosphere being usually dry and buoyant; but the character of the soil is such that most of our local societies, instituted for encouraging cottage and allotment gardening, divide the occupiers into heavy land and light sandy land cultivators, the latter having such a decided advantage over the former that it is considered impossible for them to compete together on anything like equal terms. The light lands in this district are mostly sandy loam, of scarcely sufficient texture to finish off heavy crops of grain, especially during seasons of drought; but as the Potato makes most of its growth before the effects of a dry summer are much felt, especially if the soil be well prepared, and as the crop, if rather less bulky, is almost certain to escape disease or be little affected by it, the excellence of the tubers and their good cooking and keeping qualities more than compensate for their loss in weight. The most successful cultivators hereabouts appear to be those who rest their hopes of a crop on thoroughly deep cultivation and exposure of their lands to the pulverising effects of frost, rather than on large additions of manure, which is not only difficult to obtain in country places, but often out of reach of the cottager. Deep cultivation not only ensures a suitable feeding ground for the tender rootlets, but also through drainage, so that rain readily passes through it. Light land, too, thus cultivated is several degrees warmer than heavy soil resting on a subsoil, cold, wet, and inert, a condition by no means improved by heavy dressings of manure. The soil on which our best Potatoes are grown is generally ridged or rough dug in autumn and during winter any manure, road-scrappings, or wood ashes available are spread over it. In March it is dug over again and the sets planted as the work proceeds; 2 ft. 6 in. and 3 ft. are the regular distances between rows, and as light warm lands produce plenty of weeds frequent surface-stirring has to be resorted to, not only for destroying the weeds, but also for promoting the growth of the crop. As regards varieties, new kinds are generally improvements in appearance rather than in flavour, and, as Potatoes are grown to eat, it is not surprising that cottagers who grow them and customers who buy them prefer such sorts as Gloucestershire Kidneys, English and Scotch Regents and Flukes, to more modern sorts. The main crop is generally lifted about the end of September or early in

October, when those that are diseased are separated from such as are sound, and after that the latter generally remain good. If no convenient place for storing them be available, they are placed in ridges and covered with dry straw, and before frost sets in a good thickness of soil is put over them. A change of seed has a marked influence on the crop, and should always form a part of the routine of cultivation. JAMES GROOM.

Henham.

HISTORY OF THE JERUSALEM ARTICHOKE.

THIS plant is a production of the warmer parts of the Western Hemisphere, and consequently unknown to the ancient Greeks and Romans. Sir James Smith says, in his "Introduction to Botany," that the name of this vegetable is a corruption of the Italian name *Girasole Articiocco* (Sunflower Artichoke), and was first brought from Peru to Italy, and thence propagated throughout Europe. This tuber, which is more agreeable than profitable, was, according to "Science Gossip," first cultivated in England during the reign of James I., as we are informed that in the year 1617 Mr. John Goodyer received two small tubers, not bigger than a hen's egg, from Mr. Franqueville, of London; one he planted, and the other he gave to a friend. His own brought him a peck of tubers, wherewith he stored Hampshire; but he remarks that they are meat more fit for pigs than men. This note bore the date of October 17, 1621. From this it appears that this vegetable was introduced into England by the French, who met with it in Canada, as Parkinson, writing in 1629, mentions it under the head of *Battatus de Canada*, the French *Battatus*, or Jerusalem Artichoke. Coles also, whose work was printed only forty years after it was known in this country, called it the *Potato de Canada*; but we are informed in Martyr's edition of Miller, that "it was so called because the French brought it first out of Canada into these parts; not that Canada is its original country, for it is unquestionably the produce of a hot climate, being a native of Brazil."

In Parkinson's time Artichokes used to be baked in pies with marrow, Dates, Ginger, Raisins, larks, &c., but the facility with which they increased by cultivation made them so plentiful and cheap in London that even the common people despised them, although when first introduced they were said to be a dainty fit for a queen. In the "Bath Society Papers," Vol. iv., Mr. Nehemiah Bartley, near Bristol, in 1787, gives an account of some experiments he made in cultivating this plant as an agricultural crop, and states they are about equal in value to Potatoes for feeding young pigs. But their chief recommendations are the certainty of a crop, as they will flourish in almost any soil—in the corners of fields and other waste places. Under favourable circumstances, 10 to 12 tons per acre have been grown.

The stems of this plant grow to a considerable height, and their fibre might probably be found valuable for making paper; the leaves are stated to contain nitre. In the tubers a chemical substance is found, called Inuline, which is organized, according to Raspail, like common starch, but stands, to a certain extent, in opposition to that substance, which it replaces in the root system of the composition, and has not been detected in any other tribe. Iodine gives it a yellow tint. Inuline was discovered by Valentine Rose in 1804. The Jerusalem Artichoke multiplies very quickly, and is with difficulty cleared out the land where it has once been planted. It very seldom blossoms in this temperate climate; the flowers resemble a small Sunflower.

A New Tuberous-Rooted Caraway.—Dr. A. Kellogg has some interesting remarks on a plant with the above name in the "Horticulturist." He says:—"Carum Gairdneri is a very important plant, because it promises much to the gardener and the florist. A particular description is needless, as in general appearance, and indeed in every way, it is the representative congener of the European *Chervil* on the Pacific coast. The flowers are of the most chaste white, and for an umbel the neatest we ever saw. We have had it cultivated occasionally, but never with sufficient persistence and care as to do anything like justice to it. For this reason mainly we invite attention to it, in hopes that those who can may be induced to prove its value for themselves. What is desirable is so to establish its introduction that from the garden we may possess a new dish of rare delicacy, and another charm for the flower-vase. The roots, as observed, are small, seldom over ½-in. in diameter by 2 or 3 in. long, pure white, with a creamy cuticle. Eaten raw as they are dug, they are delicious; but their sweetness and flavour are greatly improved if kept until about half-dried. There is not the least doubt that with skill in choice of suitable conditions, soil, &c., from 200 to 300 bushels to the acre could be raised. We have eaten them in soups

and various ways, and have often sent the seeds abroad, but their vitality soon perishes, unless great care is bestowed in packing, as well as speed in transit. It is a hardy plant, suited to cold climates and damp well-drained rocky, gravelly, or mixed clayey loams, especially 'dry rains.'" Have Messrs. Vilmorin, or any of our English seedsmen, any experience of this plant?

Germination in a very low Temperature.—It has been commonly stated that germination would not take place in seeds below the freezing point of water. M. Uleth, however, states that seeds of Tritium, and, indeed, other seeds also, were found to germinate when placed in grooves formed in blocks of ice.—"Prairie Farmer."

Superphosphate of Lime.—Superphosphate of lime produces a very quick effect, and besides the fertility it adds to a soil, the rapid development it ensures to plant life, enables the roots to lay hold of much food they would not otherwise procure. In the garden it is of especial value to hasten growth while plants are still small and unable to reach coarser manures, and also to touch up and bring forward any portions of crops which seem to need further help. While depending chiefly on stable and green manures, yet we always find profitable use for more or less superphosphate.—J. R.

Ashes in the Garden.—Leached ashes have an especial value on sandy soils, and have a marked effect on Onions, Potatoes, and root crops. Their value is lasting, and the results of a liberal application will be noticed for years, and, if not to be carted more than three miles, their use is profitable. Unleached ashes are especially effective when applied broadcast over Onions partly grown; in fact, they form one of the most valuable special manures for this crop, and are worth for this purpose twice the amount paid by soap-makers. For all garden crops they are valuable, Potatoes, Turnips, Beets, and Peas, deriving the most benefit next to Onions.—A. B.

Spent Hops.—Brewers' spent Hops are, in some places, so abundant as to be an important fertilizer, generally one load being equal to two of stable-manure. But I have found them most valuable, when well-rotted, for raking into the surface of seed-beds in which are raised Cabbage, Celery, and other garden plants, since they retain moisture, keep the surface loose and light, and in every way favourable for the successful growth of plants. In like manner they are excellent for any plot where you wish a most vigorous growth—vegetables for exhibition, for instance—since they furnish abundant fertility, while they keep the soil in the best condition for growth.—J. R.

Vegetables in San Francisco.—San Francisco is a paradise for vegetarians, to judge by reports of the fruit and vegetable markets there. Lettuces, Radishes, Cabbages, and Onions are always in season. New Potatoes are ready in January and last until Midsummer. Peas and Beans make their appearance in February, and linger until December. Tomatoes are in the market in March and April, and are a drug for months. The same may be said of Cucumbers; in fact, almost all kinds of vegetables can be found in the markets during the greater portion of the year. Carrots, Cauliflowers, Parsnips, Yams, Turnips, Beets, Parsley, Spinach, Cabbages, Sorrel, Rhubarb, Celery, Asparagus, Artichokes, Onions, Cress, Tomatoes, Mushrooms, Egg-plant, and scores of other vegetables are cultivated and thrive well. Strawberries, Raspberries, Blackberries, Gooseberries, Wortleberries, Currants, and other berries flourish. There is scarcely a day in the year when Strawberries cannot be obtained in the market, and they form no rare dish at Christmas dinners. Besides these articles, the market constantly affords a supply of Figs, Oranges, Lemons, Limes, Pine-apples, Grapes, Bananas, Pomegranates, Pears, Cherries, Peaches, Apricots, Nectarines, Apples, and almost all kinds of Nuts.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Making Gravel Walks.—I should be glad if any of your readers would kindly furnish me with the best way of making gravel garden paths so as to prevent weeds from growing, worms from disturbing the surface, and green tints from defacing the paths near shrubberies.—R. F. EDWARDS, Bath.

Lime in the Garden.—Lime is of most value on rich, old soils, its effect being to unlock and release fertility already in the soil, but inactive or insoluble. Hence, upon poor soils it may sometimes do more harm than good, but used upon rich, old garden soils, its use occasionally will produce astonishing results. It, however, is sometimes used with good effect on poor peat soil, such as that in many parts of Surrey.—J. R.

Lamb's Lettuce.—This long known but now-a-days too little used plant forms one of the most pleasant salads obtainable at the present season. I use it not merely as an adjunct or to mix with Lettuce, but to form a distinct salad of itself or mixed with Celery only. In this way I enjoy a distinct dish. The general mixture principle must be avoided by those who wish to enjoy good salads.—R.

The Oil-trees of China in Europe.—Attempts are being made to acclimatize this plant in France, and with hopes of success. The oil is extracted from the fruits, which yield one-third of their weight of a thick, colourless, tasteless, and odourless oil, which at a reduced temperature becomes a thick, viscid substance, possessing drying properties of the most complete type. This is probably the oil used by the Chinese in their varnish and japan-work.

Plumbago capensis and Cut Bloom.—Like Mr. Henderson (see p. 147) I find this to be a useful autumn-flowering plant. A large example of it here, planted out in the border of a greenhouse and trained over the back wall, furnishes an abundant supply of flowers all through the autumn months. When done blooming, it is kept moderately dry, and allowed a short period of rest. In the end of January it is pruned back to the old wood, and, after being occasionally syringed, breaks freely. It is allowed to ramble at liberty, and, during the summer months, receives occasional supplies of manure-water, which help it considerably. From this single plant we can cut flowers three and four times a week for months. Like Plumbago rosea, however, it does not stand long when cut.—R. GREENFIELD, Priory Gardens, Warwick.

Another way of Preserving Walnuts and Filberts.—After the Nuts have been gathered a short time a sufficient number of perfectly clean pots 5 in. in diameter are taken, and a piece of slate is laid in the bottom to cover the hole. The pots are then filled with Nuts; of which each pot holds sufficient for a dish. The pots are then covered with pieces of slate and plunged in any spare corner to a depth of 18 in. Here they remain until required for the table, and they are removed from the earth one at a time. Larger pots may no doubt be employed, but, to my mind, there is a great convenience in each pot holding just sufficient for a dish, because there is no necessity for exposing the Nuts to the air until required for the table. When preserved in this way they remain in a perfectly fresh state for a long time. (See "Gardener's Magazine.")

Rhodanthe in the Greenhouse.—That charming Everlasting, Rhodanthe Mangiesii, is in some places cultivated in pots during the winter with great success, and when in flower in the spring used for the decoration of the conservatory. It is when grown in this way that we come to realise something of its great beauty, the bright pink flowers of the old type, and the satin-like blossoms of the white variety, with their golden centres, being very beautiful. For this culture the seed is sown early in August under glass, and when the plants are large enough to admit of transplantation they are singled out and planted three or five in a 60-pot, according to their size, and placed on a shelf close to the glass, where, with a free circulation of air, they will be unharmed by damp. Moderate supplies of water are given, and as the plants require it, they are shifted into larger pots; the side branches are stopped as soon as they attain a length of 3 in., and all flower-buds are removed till the plants are thoroughly established in good-sized pots. Plants thus treated have been seen in 10-in. pots forming half spheres nearly 2 ft. in diameter, and covered with hundreds of flowers; in the presence of such specimens the valuable character of the Rhodanthe as a decorative plant is seen. The treatment needs to be liberal, and from Christmas onwards a warm growing temperature is requisite, the heat increasing as the days lengthen. This is recommended, in order that the plants should make as much headway as possible in the early part of the spring, for as the light increases the inclination of the plants to bloom is so great that it is difficult to procure them of large size. A moist atmosphere in spring, and an occasional dose of liquid manure, weak rather than strong, are of great assistance—with a fumigation now and then when green fly proves troublesome. The soil best suited for the growth of the Rhodanthe in pots is one composed of equal parts of turf and peat, with a sprinkling of gritty sand, for the winter, substituting leaf-mould and manure for the peat at the subsequent shiftings.—"Gardener's Chronicle."

The Gum Tree in Algeria.—Since the growth of plantations of this tree around the lake of Fezzara, the malaria, which formerly was intense, has almost disappeared. The village of Ain Molra, according to Captain Ney, furnishes an equally striking instance. The station was formerly so unhealthy that it was necessary to change the French garrison every five days on account of the number of men attacked. Fever has, however, become much more rare since plantations of Eucalyptus globulus have been made on the shores of the lake and the sides of the railway, which include altogether 60,000 trees.

Trees in the Garden Landscape in Winter.—Mr. J. J. Thomas lately read a very interesting essay on Beautifying Winter Landscapes, which may be done by planting trees with ornamental bark, as White Birch, Golden-barked Willow, Golden Ash and Red-leaved Ash, all of which contrast beautifully in winter when interspersed with evergreens. There are some varieties of Oaks which, when young, retain their foliage or various hues through the winter. Other trees and shrubs, as Mountain Ash, Black Alder, Sweet Briar, and others, hold bright red berries, which in winter are very ornamental.

NEW PLANTS, &c.

Cypella peruviana.—An elegant habited Peruvian Irid, bearing very showy flowers of a bright orange colour, the three shorter segments having rich purple eye-like spots, which add considerably to the brilliancy of the flower, all the segments being barred at the base with brown.

Crocus Weldeni.—This is a smallish white or lilac tinted plant supposed to be a variety of *C. biflorus*. It is a native of the limestone hills of Dalmatia, where it flowers in January and February; in this country, however, it does not bloom until March. It was introduced by the Rev. Harpur-Crewe, who received it from Major R. F. Burton, who collected it at Trieste.—“Botanical Magazine,” t. 6211.

Senecio (Kleinia) chordifolia.—A South African species having succulent stems, terete, glaucous green leaves six to ten inches in length, and six to eight flowered panicles of greenish yellow flowers. It is a botanical curiosity, but of no value whatever as a garden plant. The two best ornamental species of this enormous genus of Groundsel are *S. pulcher*, a large carmine-flowered plant, and *S. macroglossus*, which in habit resembles Ivy, and bears large eight-rayed golden flowers.—“Botanical Magazine,” t. 6216.

Pescatoria Dayana, var. Rhodacra.—One of the prettiest of the four or five varieties of *Pescatoria Dayana* now known in English gardens. The flowers in size, shape, and substance, resemble those of *Pescatoria corina*. The sepals and petals are creamy white, with purple tips; the anther case is also purple, as also is the crest and base of the oblong lip. These purple and red-tipped *Pescatorias* have been largely imported during the last year or two, and they have frequently been exhibited by Messrs. Veitch and Mr. Bull. They are all natives of New Granada.—“Botanical Magazine,” t. 6214.

Viburnum dilatatum.—A hardy white-flowered Japanese shrub, with large bright green leaves, somewhat like those of the common Hazel Nut. There are ten or twelve Japanese species of *Viburnum*, including the present plant, which promises to be a welcome addition to our gardens. Some of the *Viburnums* owe much of their beauty to the fact that they bear enlarged but abortive flowers in a way analogous to those of the Hydrangea. In the present species, however, the flowers are all normal, forming dense rounded clusters at the apex of the downy stems.—“Botanical Magazine,” t. 6215.

Ill-spelt Plant Names.—Mr. P. H. Gosse, referring to the amusing spelling of plant and other technical names so often seen in daily papers, points out in the “Gardeners’ Chronicle” that it is to bad writing more than to bad spelling that the errors are due. “The rapid mode of forming the letters, which every one is now obliged to practise, necessarily assumes that the reader (or the compositor, when the matter is to be printed) has aids to understanding the document, besides the mere form of the letters;—he catches the general sense; he knows what the writer will probably say; he knows what words will most likely be employed; in general, if only a single letter in the word be certain, the word is instantly suggested to the mind; and this is at once tested by the appearance and the number of the formless letters, and by other considerations, almost without a conscious effort. But if the words be unknown to the reader, or unfamiliar, these helps are wholly wanting. Thus, to a compositor quite sufficiently educated to decipher ordinary current hand, botanical names are perhaps totally unknown; and if these be written in the usual rapid and careless way, he has no clue to their component letters; and if the proof be not submitted to the author, small blame to the printer if his article be full of blunders.” Taking your correspondent’s examples, the two closing lines contain only common English words; and the printer has had no difficulty. Why did he set up “Frices”? No doubt the author had written “Ficus” but he had written it so that only the initial and the terminal were recognisable; the “r” and the “s” were connected by four curves, which might just as well do duty for “rice” as for “ic.” To the compositor’s mind there was nothing to suggest Ficus, rather than Frices, or Furis, or Freecis, or half-a-hundred other combinations of letters usually represented by mere touches; but this is only one form of the mischief: in the correspondence of every day, how often do we receive letters, the body of which we have little difficulty in deciphering, but of which the signature, and perhaps the address, are hopelessly illegible! Why? For the very same reason; we have no clue to guessing. We cannot possibly guess a proper name. Gosse, if written in this style, may be Gope, or Gassi, or Gersi, or almost any other uncouth assemblage of vowels and consonants. Now for

the remedy. It is not learning to spell better. And I do not recommend a forming of every letter in copy-book style; this would be hopelessly quixotic. But the evil would be met if only writers would have the consideration to put themselves for a moment in the position of their own readers; then they would write such casual words, as common sense tells them will not be spontaneously suggested to the reader, in plain round copy-book letters; particularly all proper names, and all technical terms. If this simple rule were observed, how many thousands of editors and printers, not to mention private friends, would be gladdened!

Select Rhododendrons.—Will you kindly give me the names of the best varieties of hardy Rhododendrons that bloom from May until August or September, the colours to be brilliant—say, vivid crimson, bright scarlet, vermilion, or cherry; also a few good white kinds?—M. E. A. M. [The following is a list of a few really hardy Rhododendrons, both scarlet and white kinds, that bloom from May till July; there are no hardy kinds which bloom so late as August:—*Scarlet, crimson, and rose*—Alexander Adie, B. W. Currie, Blandy-ann, Comte Gomer, Countess of Clancarty, Cynthia, Caracatus, Concessum, Dictator, Earl of Shannon, Eclipse, Frederick Waterer, H. W. Sargent, John Walter, John Waterer, Joseph Whitworth, Lady Cathcart, Lord Eversley, Lady Falmouth, Lady Claremont, Michael Waterer, Mrs. John Kelk, Mrs. John Waterer, Pelopidas, R. S. Holford, Sir J. Clarke, Sir H. Mildmay, The Crown Prince, The Warrior, Vandyk, William Austin, W. E. Gladstone. *Whites*—Delicatissimum, Exquisite, Gloriosum, Lady Guinness, Madame Carvathe, The Queen, Minnie, Mrs. John Clinton, Mrs. Thomas Agnew.—JOHN WATERER, *Bagshot*.]

Vaporisers v. Insects.—The following is the plan which I employ for destroying small insects on plants;—Every one is acquainted with the so-called “vaporiser”; consisting of two glass tubes placed at right angles to each other, one of which is dipped in a bottle of Cologne water, while by blowing into the other the water ascends, and is thrown off in very minute spray. I have adapted this principle to a strong pair of bellows, attaching bottle and all to the nozzle. Instead of perfuming the insects, however, with Cologne water, I use a strong infusion of tobacco stumps, such as have been smoked. I filter this infusion in order to prevent it from choking the tubes; then, setting the plants on a long elevated board, I shower them thoroughly on both sides with the spray, a plan so effective that not a spot as big as a pin’s head escapes untouched, and in a few hours there is not an insect visible on the plants. When I feel particularly vindictive I mix a little strychnine with the liquor. By using the bellows, I obviate the necessity of putting my mouth to the tube. Perhaps this or a similar contrivance may already be in use; it is, however, original so far as I am concerned.—PRESTON POWERS, *Florence*.

The Last Vintage in France.—The general results for the year 1875 are now known, the yield being estimated at 83,635,391 hectolitres (22 gallons each). Of the departments the Hérault stands first on the list for the abundance of its yield—9,423,193 hectolitres; then follow Charente-Inférieure, 8,694,334; Charente, 5,439,757; and the Gironde, 5,279,410. The produce of the year surpassed that of 1869 by 13 millions of hectolitres, the latter having been the most favourable for its yield in the present century until exceeded by 1875. The vintage of the latter year, however, is inferior to that of 1869 in the strength of the wine; the estimate being that the average alcoholic properties will not exceed 8°; whilst in the earlier year they were at least 10°, at which strength the most ordinary wines may be kept for two, three, and four years, whilst the wines of the quality first named require the addition of alcohol if they have to be stored or sent to any distance. In France 2,000,000 hectares, or nearly 5,000,000 acres are devoted to Vine culture, and the average production of wine exceeds 80 hectolitres; the total amounts to about 176,000,000 gallons, valued at two-and-a-half millions of francs, or £100,000,000. It is estimated that about 90,000,000 gallons of wines, spirits, and liquors together are annually exported from France, of a total value of £16,000,000. Sparkling wines enter largely into this quantity, upwards of 50,000,000 bottles being exported annually. The home consumption of wine in France is about 25 gallons per head of the entire population. The foregoing figures taken from the “Chronique de la Société d’Acclimatation,” will give some idea of the importance of this industry in France, and the urgent need of an efficacious remedy against the spread of the phylloxera. The same journal gives the average production of Spain as 30,000,000 hectolitres; Italy, 33,000,000; Portugal, 4,000,000; Austro-Hungary, 174,000; and Rumania at 600,000 hectolitres; making a total of 67,774,000 hectolitres, or about 1,500,000,000 gallons. Then there remain all the German wine-producing countries, and those of southern Russia, both yielding enormous quantities. In proportion to its capabilities Greece produces very little wine, the greater part exported coming to England.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 16TH.

At this meeting, which was somewhat thinly attended, the chief objects of interest were a showy group of hybrid and cross-bred *Hippeastra* from Messrs. Veitch and Son, several of the best of which were certificated, and a very attractive bank of *Cyclamens* from the same exhibitors. Fruiting branches of the Loquat or Japanese Medlar (*Eriobotrya japonica*), came from the gardens of Mr. R. Burn, of Blyth, Woolhampton. Several seedling Apples were submitted to the Fruit Committee, but none of any special note, if we except Gidney's Pearmain, and a large and handsome seedling which closely resembled Cellini.

First Class Certificates.—These were awarded to the following new and rare plants, viz.:—

Hippeastrum, Rev. J. Stanforth (Veitch).—A rather dwarf large-flowered variety, with broadly ovate or oblong much imbricated petaloid segments of a deep red, streaked with crimson, and having a greenish-white stripe and central star.

H. Junius (Veitch).—A deep crimson-scarlet variety, with more slender segments than the last, and a green eye, the white filaments contrasting well with the vivid crimson segments.

H. Phoebe (Veitch).—One of the most beautiful of the group, the segments being of the most vivid velvety scarlet, and the eye green.

H. Agatha (Veitch).—This has large broad petaloid flowers of a red or vermilion colour, streaked with scarlet, each segment having a greenish-white tip.

H. Sultan (Veitch).—A small-flowered variety, with rather narrow segments; deep crimson in colour with a green eye.

H. Circe (Veitch).—A large broad-petaloid flower and well reflexed; petals deep crimson with a green eye, the three lower segments having indications of a light stripe. These *Hippeastras* were, for the most part, crosses between *H. pardinum*, *H. Leopoldii*, *H. Ackermannii pulcherrimum*, and others, and their colours varied from rich crimson through all the shades of rose, white, vermilion, and scarlet, and some were striped, tipped, or margined in the most distinct manner possible.

Plants.—Messrs. Veitch's *Cyclamens* were in 48-sized pots, and each bore from thirty to forty flowers.—White rose, magenta, blue purple, and blue and crimson purple, in colour. Mr. H. James, Castle Nursery, Lower Newwood, showed a dark, richly-coloured variety of *Dendrobium nobile*, the sepals and petals of which were deeply suffused with magenta; Mr. Green, of Holmesdale Road, Reigate, furnished three plants of the bright green and elegantly cut leaved *Prenanthes elegans*, a perennial as graceful as a Palm, the result of a cross between *P. arborea* and *Sonchus laciniatus*; Mr. Stevens, gardener to G. Simpson, Esq., Wray Park, Reigate, showed *Peperomia marmorata*, a plant having dark velvety green leaves, ovate in shape, and conspicuously marbled with silvery grey.

Fruit.—A fine dish of Gidney's Pearmain Apple, said to be a seedling from Cornish Gillyflower, was shown by Messrs. Lumboe, Pine, & Co., of Exeter. It is a variety quite distinct in colour from Cornish Gillyflower, but somewhat like it in shape; its flavour is rich and juicy, and the variety well deserves culture as a handsome late dessert fruit. Mr. J. McLaren, Ash Vale, contributed a dish of large greenish-yellow Apples suffused and streaked with red; the specimens sent were as large as those of Blenheim Orange, of an ovoid shape, with the deep eye of Cellini, which the Committee thought it too much resembled to merit any award. Mr. H. Colbourn, gardener to R. Burn, Esq., Blyth, Woolhampton, sent cut branches of the Chinese Loquat (*Eriobotrya japonica*), well furnished with excellent fruit, which is borne in terminal clusters of five or six together, each being as large as a crab, and of a soft orange-yellow colour; their flavour somewhat resembles that of a sour Apricot. The Loquat may be fruited with tolerable regularity in a cool conservatory or orchard-house, and even out of doors in warm sheltered localities it is well worth culture. Messrs. Rivers, of Sawbridgegorth, showed specimens of a German Apple received from Stuttgart under the name of Breiting. It is a large, heavy, yellowish-coloured variety, dotted with green something like Northern Greening, and, like that variety, is said to be an excellent cooking Apple. Mr. Harrison Weir contributed a handsome dish of Blenheim Orange, some of the specimens of which were quite crimson on the sunny side; this, as is well known, is one of the most useful of all Apples, but it is rarely seen so highly coloured as in this instance; from the same exhibitor came a dish of Josephine de Malines Pear, named Matthews Dilia; the Rev. G. Kemp sent a dish of Joly de Bonseur Pear, a rather large variety, in a state of excellent preservation, and covered with deep reddish russet; Messrs. Lane, Berkhampstead, furnished examples of a yellow striped Apple, deep dull crimson in colour, dotted with yellow, from Mr. F. Bonnal came specimens of a small yellow Apple, named Campmount Pippin, a kind possessing little merit.

Vegetables.—Mr. Pottle, Sudbourne Hall, contributed Barbe de Capucin and Witloof, the latter considerably the stronger and more succulent of the two. Both, when blanched, are useful for salads, and even for stewing if thought desirable. The same grower showed two excellent varieties of Dandelion in good condition. Mr. Moore, Fötter's Bar, sent a boxful of his Cucumber called Duke of Edinburgh, each fruit of which measured from 10 to 12 in. in length, although grown without bottom-heat. Mr. P. Bonnal showed examples of a seedling Onion resembling the Brown Spanish, and Mr. H. Weir furnished a seedling red or purple Potato named King Harry, possessing apparently little merit.

A New Use for Wood.—The application of wood for stuffing beds seems, at first sight, an anomaly, nevertheless, a patent exists which moreover appears to be quite practicable, for disintegrating the wood of various kinds of Pine, so that it becomes as light and elastic as hair. The resinous properties of the wood cause it to be very healthy, and to act as a preventive against vermin. It is producible at a price far below that possible for any other material, except straw and seaweed, in quantities as low as 4s. per cwt.

Royal Horticultural Society's Officers for 1876.—The Council and Officers for the current year consist of the Right Hon. Lord Aberdeen, President; Mr. Henry Webb, Treasurer; Dr. Hogg, Secretary; the Earl of Mount-Edgumbe, Lord Alfred S. Churchill, Hon. and Rev. J. T. Boscaven, Sir Trevor Lawrence, M.P., Mr. F. Campion, Mr. G. T. Clark, Col. R. Trevor Clarke, Dr. Denny, Mr. William Haughton, Mr. W. B. Kellock, Mr. P. W. S. Miles, and Mr. Robert Warner. The Earl of Mount-Edgumbe and Mr. T. Clark were elected, at a special meeting held after the adjourned annual general meeting on the 10th inst., to fill the vacancies caused by the resignations of Admiral Hornby and Mr. A. Grote.

Sensation in Plants.—M. Figner believes that a plant has the sensation of pleasure and pain. Cold, for instance, he says, affects it painfully. We see it contract, or, so to speak, shiver under a violent depression of temperature. An abnormal elevation of temperature evidently causes it to suffer, for in many vegetables, when the heat is excessive, the leaves drop on the stalk, fold themselves together, and wither; when the cool of evening comes, the leaves straighten, and the plant resumes a serene and undisturbed appearance. Drought causes evident suffering to growing, for when they are watered after a prolonged drought they show signs of satisfaction. The Sensitive Plant, touched by the finger, or only visited by a current of unwelcome air, folds its petals and contracts itself. Desfontaines saw one which he was conveying in a carriage fold its leaves while the vehicle was in motion, and expand them when it stopped—a proof that it was the motion that disturbed it. Sensation in plants is of the same kind as in animals, since electricity kills and crushes them as it does animals. Plants may be also put to sleep by washing them in opium dissolved in water, and hydrocyanic acid destroys their vitality as quickly as it does that of animals.

NOTES AND QUESTIONS—VARIOUS.

Drawing-room Vase.—Last week we filled a large vase as follows, viz. the Valley in the centre, and Scarlet Doe Van Thol Tulips and *Solila sibirica* round the edge, alternated with Maidenhair Fern, a combination both effective and pretty.—R. G., Priory Gardens, Warwick.

Double-flowered Chinese Plum.—Plants of this furnished with thousands of white blooms are now very useful for cutting from, and well deserves more attention than they generally receive. Plants introduced in heat in the end of December have been in full bloom for three weeks.—R. GAZERDIN, Priory Gardens, Warwick.

The Newtown Pippin as a Cooking Apple.—In illustration of the proposition that the best eating Apples are often also the best cooking Apples, I wish to say that I have lately tried this Apple—and by no means good specimens of it—as a cooking Apple, and found it the best I had ever used, deliciously rich, and without having a clean and most pleasant flavour. It is, in a word, perfect, without the addition of sugar or other accompaniment.—W.

Celastrus scandens.—What does "W." mean (see p. 165) by "properly growing" this plant? Many years ago, I raised a batch of seedlings of it which have been planted in different situations, both here and elsewhere, yet none have ever fruited, or even bloomed. Perhaps "W." can tell me the reason I find it to be a plant that is easily propagated; for, if, transplanting, pieces of the root be left in the ground, they become plants like the Bramble and others.—J. M.

Rose Princess Louise.—In the description of my seedling Rose Princess Louise (see p. 156), it is said to have been raised between Mrs. Rivers and Madame Vidoi a statement that is not quite correct. It was a seedling from Madame Vidoi fertilised by the black white Hybrid Perpetual Virginalis, and was an effort made to fulfil the requirements for a prize for a white English raised seedling Rose at the York show, and although it is not perhaps the freest-flowering Hybrid Perpetual, it is the freest-flowering white Rose in that class.—THOMAS LAXTON, Stamford.

The Beech Aphid.—I send you a portion of bark taken from a Beech tree which you inform me what the disease is with which it is affected, and the best way to get rid of it? So thickly does it cover the bark that many of the trees have the appearance of having been whitewashed.—Z. J. A. [It is the exudation from a species of Aphid named Aedeagus Fagi. When plentiful, as in your case, and on large trees, we know of no remedy; on a small scale, it may be removed by the usual processes of brushing and painting with insecticides.—A. M.]

Early Pruning v. Late Pruning.—In the early part of December I had a quarter of Gooseberries pruned, to enable me to have the ground amongst them manured and dug. This I have found to be a great mistake, as it gives the birds a better chance to take the buds, and, upon examination, I find that the trees pruned have lost one-half of their buds; while others close by unpruned, have been left untouched. The same thing, too, holds good in the case of Currants, Plums, and Cherries—kinds of fruit of the buds of which birds are fondest. Therefore autumn pruning is an operation to be guarded against as regards such trees. I used formerly to prune early in March, and have generally had good crops.—H. R. MANX, St. Vincent's, Grantham.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

KING PLANTS FOR TABLE DECORATION.

THE *Anectochilus*, or King Plants, as they are sometimes called, belong to one of the most beautiful classes of fine-foliaged plants; they are mostly dwarf and compact in habit, and a few of the free-growing kinds among them are very suitable for table decoration. The foliage of all the species is superb; in some the ground colour is a rich olive or purple, interspersed with a network of gold; in others it is a bright velvety-green, netted with silver, which, under an artificial light, is strikingly effective. The reason why the *Anectochilus* are so seldom seen in cultivation arises from the idea that they are difficult to grow except in a high temperature. This is a mistake,

An *Anectochilus* or King Plant.

as many of the most useful varieties of them, especially those that are suitable for table decoration, succeed well in a vinery; indeed I have grown capital specimens under the following treatment:—The plants should be kept cool and dry during the winter months. I never give any water from the commencement of October to the early part of February, the atmospheric temperature being maintained at about 60° at night, and 65° by day. As soon as the plants begin to move, they send up a bloom-spike which should be removed with the point of a sharp knife, an operation which causes the plant to break from every joint; in fact, I have had *A. argenteus* and its variety *pictus* strong enough to push fourteen shoots from a single stem. As soon as the young shoots have made an inch of growth, I take a sharp knife and cut the old stem through between each joint, keeping the bell-glass under which they are placed close for a fortnight or so, when they may be potted off, either singly in small pots, or several in a pot of a suitable size. The pots should be filled with broken potsherds to within 2 in. of the rim, and covered over with freshly gathered Sphagnum, filling up with fibrous peat, liberally mixed with clean potsherds and silver sand. Lift each plant carefully out with the old piece of stem adhering to the young plant; if there should be any appearance of decay after re-potting, remove it with a sharp

knife at once, and sprinkle the cut with a little fresh lime which prevents further damage. In re-potting surface with Sphagnum Moss, which, if pressed down at interval as may be required, has a pretty effect. Then give the whole a gentle watering, and keep the bell-glasses closed until the young plants have become established, when a little air may gradually be given by placing small pieces of wood under the edges of the bell-glass, so as to lift it up equally all round, always avoiding cold draughts. As the plants attain full growth, the bell-glasses may be taken off when the vinery is closed, a practice which tends to ripen the stems well, and which prepares them for the cold winter months. Let them have all the light possible, but shade them from the sun. Never water or syringe them overhead, as the water gets into the axils of the leaves, and sometimes causes them to damp off; and, as the plants are to be used for the table, it is better to be rather on the side of dryness than otherwise, when, with care, they may be used without the plants sustaining the least injury. By getting the growth matured early in the autumn, and giving the plants a cool dry rest in winter, the following varieties may be employed for table decoration, and maintained in vigour for many years, viz.:

ANECTOCHILUS (*Physurus*) *ARGENTUS*.—A free-growing species, the leaves of which are from 2 to 3 in. long, and prettily marked with silvery veins on a light green ground.

A. ARGENTUS PICTUS.—A distinct, vigorous-growing variety, the leaves of which are from 3 to 4 in. long, each leaf having an edging of dark green, with a beautiful band of frosted silver down the centre. This is one of the best for table decoration, as the bright silvery band shows itself off to advantage under artificial light.

A. MACULATUS.—This is a pretty kind, the leaves of which are 2½ in. long, and spotted with white parallel with the midrib, on a dark green ground.

A. LATIMACULATUS.—A distinct and free-growing variety, with dark green leaves and silvery markings.

A. PETOLA.—Of this there are two varieties, one more distinct in the marking than the other; both are, however, pretty; it is, in short, the best of the green-leaved varieties. It grows freely and increases fast; its leaves are 2½ in. long, overrun with gold in well-defined lines, on a pale green velvety ground. It grows freely in a vinery or close greenhouse.

A. STRIATUS.—This grows from 4 to 5 in. high, and has leaves from 2 to 3 in. long, dark green, with a broad band of white down the centre.

A. INTERMEDIUS.—A free-growing kind, with a good constitution. Its leaves are from 2 to 3 in. long and 1½ in. broad, with a dark olive velvety surface, beautifully veined with gold.

A. SETACEUS.—One of the oldest kinds in cultivation, and still one of the handsomest, its leaves being of a beautiful velvety green, about 2 in. long and 1½ in. broad, and richly netted with gold. Of this there are several varieties, all remarkably handsome and free growers.

A. XANTHOPHYLLUS.—This is distinct from any other variety in cultivation. It grows to the height of 4 or 5 in.; its leaves are from 2 to 3 in. long, and 1½ in. broad, with a dark velvety green ground, striped with broad orange and green down the centre, and beautifully covered with a golden network. It is a free grower, and as a decorative plant one of the best.

A. DAWSONIANUS.—A useful and ornamental species, the leaves of which are almost black, very glossy, and beautifully covered with a crimson network. Its flowers, which are white, are freely produced and very useful for bouquets.

Waterdale.

JAMES SMITH.

Plant Collecting in Corsica.—My Corsican tour was in all respects a great success. I gathered upwards of 100 plants in flower, Alpines and others. Corsica geologically is very varied in formation; granite is the foundation, but, coating a portion of the granite eastwards, is carboniferous and other allied limestone. Think of *Crocus minimus*—a little darling—opening in January, and two lovely *Alliums*, rose and white (*substrisum* and *neapolitanum*), in full bright enticing flower. One friend is so delighted with my account of Corsica, that he talks of sending out a collector at once to canvass the Restonica Valley, where the lovely *Cheilanthes odora*

teems, as does *Gymnogramma leptophylla*, finer than it grows in the Channel Islands. I shall make you long to have been with me, when I talk of *N. Marantæ*, *N. vellea*, *Pteris cretica*, *S. Hemionitis*, *P. Instaniticum* being among Corsican Ferns, and rarities among the Phenogams, that I have not time to specify.—PETER INCHEBALD, *The Lodge, Hovingham, York.* Feb., 1876.

AN EASY WAY TO INCREASE HYACINTHS.

I HAVE always found it difficult to obtain a sufficient quantity of yellow Hyacinths. Dealers rarely ever include more than one bulb of this colour when you send for a dozen, and often that turns out to be only a dirty buff or nanken colour. A few years ago, having obtained a really good bright yellow variety, I determined to propagate it, which I did in the following manner:—After the bulb had flowered in a large pot, and the foliage had turned yellow, which it soon does if you place the pot on its side out-of-doors, and cease giving water, I took the bulb out of the pot, twisted the foliage off, and also the roots. I then laid the bulb on a dry border, under a south wall. In a short time it began to split open and to produce small bulbs. About the end of September I made up a small bed containing a quantity of decayed cow-manure, mixed with soil and sand. In this the little bulbs were planted 6 in. apart the first year, and every year afterwards 9 in. apart. Some of them showed flowers the first year, but these were nipped out as soon as they made their appearance. The bulbs were lifted every year for three seasons in July, and they were not allowed to flower, which had the effect of strengthening their growth. After growing them in this way for three years, I was rewarded with some very fine bulbs, which flowered splendidly the following season. After blooming in pots, I always cut the flower-spike out as soon as its beauty is over, and remove the pots to the reserve garden, plunging them quite up to their rims. Sometimes the bulb will be found to be quite plump, especially if it has not been forced, and in that case it may be bloomed again the following season; but as after blooming it naturally throws out off-sets, the best plan is to grow these in separate little beds, labelling them so as to indicate their colour and name.

A Hyacinth bulb of any favourite sort or colour may be increased in the manner just described. In Holland, as with us, the Hyacinth, when it has grown to its full size, produces its finest spike of bloom, and then furnishes off-sets. These Dutch cultivators grow in the manner just related, and, at lifting time, pick out the largest and heaviest bulbs for the English market. It is true, that a full-grown heavy bulb will produce a good spike of bloom in water, but that bulb is worthless afterwards, except for purposes of propagation. Hyacinths should be taken up every year, whether grown in beds or in borders, and the off-sets of any good variety should be planted in a reserve bed made up of rotten cow-manure, leaf-mould, and sand, until they attain a sufficient size to be again grown in pots or glasses. The consumption of Hyacinths in this country is enormous, and the annual cost of procuring a good collection for a large establishment forms a considerable item in gardening expenditure. Hyacinths bought at auction sales nearly always disappoint the purchaser, inasmuch as they are made up of the refuse of the Dutch nurserymen's stock, and consist of only such sorts as have small bells and short flower-spikes.

As regards cultivation both in pots and glasses, little need be said. October and November are the best months for potting, and, whether grown in pots or glasses, they should be kept in a dark place until plenty of roots have been made and the bulbs have shot about $\frac{1}{2}$ in. In potting, remember that the soil cannot be too rich. The pots should then be plunged up to their rims in the open ground, and covered a few inches with ashes or cocoa-nut refuse until the plants begin to shoot. Town growers might place their pots in a dark cellar, or, if in glasses, in a dark cupboard. For window culture, three bulbs may be grown in an 8-in. pot filled with rich compost. Good rich soil without forcing will produce fine colour, stout growth, and noble spikes of flowers. The Hyacinth always well repays any trouble that may be taken with it, provided good bulbs free from disease are planted. If grown in water, remember that rain-water is best, and that

it should be changed every week. The glasses should be dark coloured. Hyacinths will bloom in even the darkest kitchens in our large towns, and if the bulbs be good, even ill-treatment will not destroy the flower. H. TAYLOR.

Bedale.

PRIMULA ALTAICA *versus* P. VULGARIS GRANDIFLORA.

"A. D." (see p. 122) has suggested that the name *P. vulgaris* *corulea* would have been a very appropriate title to give to this really beautiful but misnamed plant. Permit me to state, which I did not in my article on *Primroses*, that there was a *Primrose* cultivated in these gardens some twenty-three years ago to which that title was given, and most deservedly so, for its colour was much nearer a decided blue than the one so long known under the name of *P. altaica*. Whether it be in existence at the present day or not, I am not aware, but much fear it is not. On referring to my memorandum I find I sent away two plants, but in reply to inquiries I have made, I find they are dead, and have been for years. Undoubtedly it was the plant that par excellence should have had the name *P. vulgaris* *corulea* applied to it—possibly it may yet be in existence, and if my article on *Primroses* should be the means of discovering its whereabouts, then all I have to say is that, as the writer of the article, I should consider that I have had a rich harvest. "B." (see p. 176) alludes to an intermediate form between the old species *P. cortusoides* and the japonica variety *amœna*. Since writing my article on *Primroses*, I have come across some notes taken at the Manchester Exhibition a year or two ago regarding a form of the latter, which was exhibited under the name of *P. cortusoides* *amœna* var. *intermedia*, and which appears to agree with the one he alludes to as figured in the "Magazine of Botany" under the title of *P. Pallasiana*. I have no opportunity of referring to the work named, but I remember distinctly being struck with the appropriate character of *intermedia* as applied to it. Seeing, therefore, what we have done for the *Primula sinensis* as compared with the old original type, we ought not to begrudge a similar honour to the Japanese in respect of what they have done for the old Tartarian species *P. cortusoides*, and we ought further to bear in mind that what we have succeeded in doing in a score of years they may possibly, as regards their species, have occupied a score of centuries. In their "History of Gardening" Parkinson and Gerard in producing may be looked upon as children, whereas we consider them as representing almost the ancient of days. Allow me, in conclusion, to thank the various contributors of *Primulaceous* lore, which collectively forms a most important addendum, and one which will be fully appreciated by your readers, to my article on *Primroses*. There are, however, yet two or three names that I have in my mind's eye who have made themselves familiar with our European *Primulas* at last in their native habitats, and from whom some valuable information may yet be forthcoming.

Hull Botanic Gardens.

JAS. C. NIVEN.

NOTES ON OXALISES.

I SHOULD feel much obliged if any of your correspondents could give me some information concerning the following species of *Oxalis* and the names of their authors:

<i>Fansthola</i>	<i>longisepala</i>	<i>controversa</i>	<i>Consolei</i>
<i>venusta</i>	<i>bonariensis</i>	<i>Tweediana</i>	<i>Compalerii</i>
<i>concinna</i>	<i>fragrans</i>	<i>lutea</i>	<i>majorana</i>
<i>isopetala</i>	<i>Ehrenbergii</i>	<i>odorata</i>	<i>granulata</i>
<i>triactyloides</i>	<i>iliciana</i>	<i>Coppolarii</i>	<i>lactiflora</i>

Oxalis *Pansthola* I received from the Edinburgh Botanic Garden—it is certainly *O. pentaphylla* (Bot. Mag.). *O. concinna* (received from Mr. Tyerman) is *O. versicolor*, as is also *O. discolor* (received from the Botanical Garden of Montpellier). *O. isopetala* (from the Botanical Garden of Algiers) is *O. flava* (L.). *O. triactyloides* (from the Botanical Garden of Montpellier) is *O. hirta* (Jacquin), as are also *O. longisepala* (from Edinburgh), *O. canescens* (from Paris), and *O. multiflora* (from Edinburgh). *O. bonariensis* (from Edinburgh) is *O. floribunda* (Lohmanni), a very common hardy *Oxalis*, which I have received under the names of *O. arborea*, *O. Tweediana*, *O. multiflora*, and *O. controversa*. *O. fragrans* (from Botanical Garden of Algiers) is *O. livida* (Jacquin). *O. Ehrenbergii* (from Edinburgh) is *O. cernua*. *O. iliciana* (from Mr. Maw), *O. lactiflora* (from Messrs. Hooper), and *O. granulata* (from Botanical Garden of Edinburgh) are *O. incarnata* (Jacquin). *O. lutea* (from Kew) appears to be a stemless variety of *O. carnosa* (Molina); this last plant I got from the Colchester Bulb Company, under the name of *O. arborea lutea*. *O. odorata* is a distinct species (received from the Colchester Bulb Company), with fragrant lilac flowers, and the habit of *O. floribunda*. *O. Coppolarii*, *O. Consolei*, and *O. Compalerii* (from the Botanical Garden of Algiers) do not appear to be distinct from *O. asinina* (Jacquin), but I have not yet been able

to flower them. *O. majorana* (from the Botanical Garden of Algiers) appears to be identical with *O. fabrofolia* (Jacquin).

The correctness of the names of the species of *Oxalis* is very difficult to preserve in a collection, owing partly to the elasticity of the seed-pods, scattering the seeds in all directions, and also in the minute bulblets falling amongst the earth used for potting. Jacquin has also added to the confusion of the genus by creating so many species; Harvey and Sonden in their "Flora Capensis" have united a dozen of his species under *O. variabilis* (Lindl. Bot. Reg.), four under *O. tubiflora* (Jacquin), and three or four under *O. hirta* (L.). Jacquin has left us a legacy of a model collection of beautifully executed plates to perpetuate his fancies, in the same way as Jordan has done with the creations of his imagination. I have been employed for several years in making a living collection of the genus *Oxalis*, and have received from different sources nearly ninety species by name, which, when eliminated, may amount to about fifty distinct species. GILES MUNBY.

The Holt, Farnham.

Dictamnus Fraxinella.—While fully endorsing all that Mr Williams has said (see p. 175) as to the value and beauty of the *Dictamnus* as a herbaceous plant of the very first quality, and one whose absence in any collection must be looked upon as a most important blank, permit me to suggest that the generally accepted name, and that adopted by Linnæus himself as the title for the genus, was the *Dictamnus*, the specific name being *Fraxinella*. It is in point of fact the Ash-leaved *Dictamnus*, whereas your correspondent has reversed the titles. The generic title *Fraxinella* would literally mean a small sort of Ash tree, and seeing that it bears no relation, structurally speaking, to the Ash, although as a species the title may be appropriate enough, it is better to retain its true generic title of *Dictamnus*. In addition to your correspondent's remarks, I might add that its seeds, even when sown as soon as ripe, have, according to my experience, the happy, or rather unhappy, knack of vegetating freely and dying off equally freely; a more certain mode of propagation is by means of the fleshy roots, which, if cut into pieces in the spring, will strike freely and form buds much sooner than the seedlings.—J. C. N.

Rhododendron argenteum.—I paid a visit to Osberton a short time ago, and was much struck with the magnificence of a plant of this *Rhododendron*. It was about 15 ft. high, and bore some sixty trusses of bloom, some of them 15 in. in diameter, truly a grand sight. A whole house at Osberton is to be set apart for the growth of this and other *Rhododendrons*, such as *Nuttallii*, *Aucklandii*, and *Falconeri* among tall-growing kinds, and for *Princess Royal*, *Jasminiflorum*, *Princess Alice*, and *Veitchianum* among dwarf kinds. These, well placed as to contrast, cannot fail, when in flower, to be highly effective.—W. ATKINSON.

Dead Sea Apples.—There grows on the ramparts and old Castle of Bastia, a Nightshade that yields the so-called Apples of the Dead Sea. They are doubtless the work of a *Cynips*, that pierces the berry and utilises it for the food of its offspring. I looked and inquired in vain for evidence of this *Cynips*. The berries were tolerably plentiful on the scrubby plants, yellow and pendent, and slightly larger than our Potato-apples. The seeds were possibly first introduced into Europe in the soil, probably with the Date or Pomegranate, and this may account for the absence of the insect. The shrub itself is about the size of a Gooseberry bush, prickly alike on the leaves and stems, with the branches strangely contorted and overlapping. The flowers are of a dirty white. The plant becomes historically interesting, bearing as it does evidence of Saracenic origin in the Mediterranean Islands during the Middle Ages; and during my recent tour through Corsica I noticed other vegetation that similarly indicated Eastern invasion and occupation.—PETER INCUBALD, *Hovingham Lodge, York.*

Models of Flowers.—Professor Maisch exhibited the other day a series of botanical models, made by Mr Robert Brendel, of Berlin, Germany, which have been recently imported, to be used for the illustration of lectures on Botany and *Materia Medica*. These models are faithful representations of the flowers and other parts of plants belonging to different Natural Orders, magnified to such an extent that the different parts can be readily seen at some distance; they are painted in the natural colours of the organs which they represent, and many of them can be taken apart so as to exhibit their internal structure. Among the models shown, were those of *Aconitum Napellus*, *Viola tricolor*, *Conium maculatum*, *Hypericum perforatum*, *Asperula odorata*, *Digitalis purpurea*, *Colchicum autumnale*, *Atropa belladonna*, the flowers of the Potato, Strawberry, Apple, Cherry, and others; the entire series comprising sixty-five numbers, of which twenty-five consist of from two to four distinct models.

LANCASHIRE SHOW GOOSEBERRIES.

About sixty years ago, when trade was prosperous in Lancashire and when workmen could earn about 15s. per day, many devoted their spare time, of which they had more on their hands than workmen now-a-days have, to growing Gooseberries. They also raised new varieties every year to which they gave fanciful names, and Lancashire became the leading county for Gooseberry shows, for which it is still famous. Nottingham and Derby were also noted places for Gooseberry shows, rules for which were carefully drawn up, and prizes offered, consisting of silver cups and similar awards. The fruit was generally exhibited in four classes, viz., red, white, green, and yellow. The judges had no great difficulty in deciding who were the winners, they merely weighed the Gooseberries, and wrote on a card their weight with the name of the winner. Some would weigh as much as from 20 to 30 dwts., and occasionally more. London, a red kind, is often grown above 30 dwts., and Catherine, yellow, 29 dwts. The heaviest berry of any colour always took the premier prize. Weight of the fruit was the principal object aimed at, and many were the nostrams used to attain the desired end. After the show, its promoters always spent an agreeable evening together. In some of the nurseries in Lancashire, Gooseberry propagation is still made a specialty. Strong soil is the best for bringing the Gooseberry to perfection, but plenty of manure effects wonders in any soil. Gooseberries should be grown in an open airy situation, and the trees should be liberally manured every year. They should not be planted at a less distance than 6 ft., and the ground should be stirred deeply and well manured. The roots should be carefully spread out on the top of the newly-prepared soil, and covered about 3 in. deep, treading the soil down gently with the foot. Many of the show Gooseberries have bad habits of growth, throwing out long straggling shoots, and, in order to keep trees of this class in form, a wooden hoop is placed over them, supported by a few small stakes, and the long straggling shoots are raised up and tied to the hoop; others are trained to a few small stakes placed round the trees; the pruning consists in cutting out all weakly and unripe shoots, and such as cross one another, leaving two or three strong laterals on each main branch; the end or leader of each limb should also be left, if not too straggling, but, if so, it should be cut back to a good wood-bud. The fruit grows on old as well as new wood, but the finest is always produced on wood of the previous year's growth. In growing for exhibition, the long shoots of the previous summer are always preserved, and a good portion of the old wood is cut back in order to produce strong new wood for the next year's crop. When the trees appear to be making too much wood in summer, numbers of misplaced shoots are cut entirely away in June; more sap then flows to the fruit, which afterwards begins to swell. The new shoots are tied to the hoops or stakes, and the trees are thus kept in the form of a cup. Growers for exhibition do not prune on the spur system having found by experience that a well-ripened stout shoot always produces the finest fruits. The latter should be well thinned as soon as they are as large as Peas. In about a fortnight they are thinned again, whether wanted for tarts or not; and as large fruit is the object aimed at, about half-a-dozen to each tree are only allowed to remain. The fruit left to ripen is swelled off by fastening small cans of water on the branches, into which the brown calyx of the fruit hangs, so as just to touch the water. The fruiting branch has therefore to be tied very firmly, so that no wind can possibly move it. Should the weather be dry when the fruit is swelling off, liquid manure is applied, and generally also throughout the growing season abundance of water is given, so as to prevent the berries from cracking, which otherwise sometimes happens after a heavy shower. The trees should be heavily surface-dressed every winter, and in February the dressing should be forked not dug in, the aim of the cultivator being to keep the roots near the surface. For exhibition purposes, trees not under four years old are best, and these are rarely retained by successful growers after they reach their eighth year.

The following are a few of the heaviest and best flavoured amongst the large kinds, viz., Moreton Hero, red; Napoleon, red; Slaughterman, red; Thumper, green; Catherine, yellow; London, red; Navero, green; Dan's Mistake, Hero of the Nile, greenish white; Jolly Fellow, red; Turn-out Rifleman, red; Ware's Nelson, orange yellow; King, dark yellow; Shiner, light green; Trumpeter, orange yellow; Sportsman, red; Birdlime, yellow; Bonnie Rodger Duckwing, yellow; Lion's Provider, bright red; Advancer, green; Whitesmith, Miss Nightingale, greenish white; Drill, deep green; Queen of Trumps, greenish white, smooth. The three Chapagnes are the richest in flavour; they are of medium size and excellent bearers; colours, red, green, and yellow, all a little hairy. For preserving, Warrington, Aston, and Ironmonger are the best. H. T.

NATURE gives us volumes of fruit, which she always prefaces with flowers.

Renovating Old Apple Trees.—Having had the management of an orchard for some years, and finding that some of the oldest and finest trees in it were shy bearers, or bore small and comparatively worthless fruit, after mature consideration it was determined to improve, if possible, a few of the oldest trees, some of which are about seventy years of age. It may have been remarked that when trees of considerable size and age are headed back and regrafted, they grow vigorously for a year or two and then die. The cause of this disaster is doubtless the check given to the trees by severe heading down, the head being disproportionately small compared with the roots which, during the preceding year, supplied a large top. The latter having been removed, the roots become comparatively dormant, and many of them die or become deceased, thus affecting the whole tree, and in a few years death is the result. In renovating old trees, the best plan is not to head them too much back, but to graft them liberally: on large old trees as many as 100 grafts may be put on each. Under such conditions the whole will grow and make healthy vigorous shoots. All the shoots made below the grafts on branches should be allowed to remain, in order to encourage and keep up a healthy root-action, but they should be gradually removed as the grafts increase in size and form a head. The clay used in grafting should remain on until it falls off of itself, as it forms a protection against winds and storms, and by using dry leaves of the Water Flag, cut and stored the previous autumn, for tying, no harm is done to the bark, as is the case when bast is used. The Flag rots and bursts as the grafts grow. Trees for grafting should be headed back about this time, and grafted at the end of March or beginning of April. Grafting is a good way to increase rapidly any approved kind of Apple. The grafts should be of a stronger growing kind than the stock, or at all events not less vigorous, as strong kinds have a beneficial effect upon the ultimate vigour of the tree. The Margil is an example of a weak-growing orchard Apple tree, although it is one of the best dessert kinds, while Autumn Pearmain, Wellington, Blenheim Orange, Gravenstein, and Warner's King are among the best free-bearing and strong-growing kinds.—J. GARLAND, *Kilberton*.

Lee's Prolific Black Currant.—This, says Mr. Saul in the "Florist," is the best variety in cultivation. It is large in size, a great bearer, and hangs long on the bushes. When quite ripe, it is excellent for dessert. There is a sort here very like it in every respect, which I have exhibited for many years at the local shows, and for which I have received many prizes, but I consider Lee's Prolific to be a better variety. I would strongly recommend it to all intending planters, as I feel certain that, under ordinary management, it will give satisfaction. When good varieties of fruits can be had, inferior sorts should never be planted, as they occupy the same space and require as much labour in after-management as good ones. Though the Black Currant will grow and bear well on any tolerable garden soil, it does best on well-enriched land. After the bushes come into regular bearing condition, they should annually receive a good dressing of rotten manure, which should be lightly dug in; deep digging should be avoided, as the bushes form a great quantity of fibrous roots near the surface, which deep digging seriously injures.

Gilbert's Victory of Bath Melon.—To avoid misapprehension, allow me to say, in reply to "M. T." (see p. 183), that in applying the term "not prolific" to this Melon, I used it in a comparative sense. When one finds that a certain variety constantly bears twice as many fruit as another variety—other things being equal as regards culture—I describe the one as prolific and the other as not so.—I think that 100 per cent. difference is something. "M. T." says, "without removing the plants from the pots in which they were sown, I plunged them in 11-in. size," and the pots were filled with strong soil and well rammed, and the plants allowed to make 6 ft. of growth before stopping. Now I submit that if the very shyest-bearing Melon refused, not only to bear, but to bear freely under such "high-pressure" treatment, either the Melon or the cultivator must be sadly to blame. Really "M. T.'s" testimony is but "faint praise," and all but corroborative of my statements. I have been a buyer of all Mr. Gilbert's Melons, I think, always taking his name as a guarantee in such matters, and I feel sure he will not take it amiss to have both their good and their bad qualities pointed out.—J. S.

A Use for Whiskey at last.—For exterminating mealy bug, a correspondent of "Moore's Rural," recommends common high-proof whiskey. With a small soft brush one can soon clean the bugs from 100 plants, no matter how badly infested. Dip the brush into the whiskey, and then let a drop or two fall upon a cluster of mealy bug, and they will disappear. There are some very delicate kinds of plants which the whiskey will injure if used too freely; but there is not much danger in its application to the ordinary kinds cultivated in greenhouses. Notwithstanding this we should not advise anybody to add whiskey to their garden stores, as common alcohol will do as well or better.

NOTES OF THE WEEK.

—THE pretty Star and Common Anemones that at this season dot the warmer valleys on the French shore of the Mediterranean may now be seen in bunches in Covent Garden. They travel better than might have been expected.

—MESSRS JACKMAN, of Woking, have made arrangements to hold another exhibition of Clematises in the Royal Botanic Society's Garden, Regent's Park. It is to be opened on the 1st of May next, when a fine display of these showy plants will doubtless be made.

—MR. PETER HENDERSON, writing in the "Gardeners' Monthly," warns people against the mistake of painting hot-water pipes in greenhouses with gas tar, which often leads to great damage. It is needless to add that it should not be used on any other surface in glass-houses.

—IN some investigations into the question of the growth of plants as affected by latitude, Hoffman states that from numerous observations in Central Europe we may conclude, as an average, that a difference of latitude of one degree causes and implies a delay or retardation of 3½ days of the various steps in the development of plants, especially as regards their blossoming in spring.

—MR. DEAN'S seedling coloured Primroses are already very attractive in his grounds at Bedford. The introduction of these richly-coloured varieties of our British Primrose into general garden cultivation is much to be desired, as no plants are more easily grown, and none are more suitable for the wild garden, herbaceous borders, and the fringes of shrubberies.

—IT is said that about 15,000 bunches of Violets are sold every day in Paris. Their sale amounts to 500,000 francs a year. They are not in so much favour now as they were during the Empire, for the Violet is looked upon as an emblem of the Bonapartes. Great numbers of persons live by its sale and its culture in the sandy fields to the south of Paris.

—AT a meeting of the Royal Horticultural Society, held on Thursday last, the "Amended Summary of the Privileges of Fellows for 1876" was unanimously adopted. Among newly introduced features, the following will doubtless be interesting to gardeners:—"Non-transferable tickets at 10s. 6d. per annum, admitting to all shows, scientific meetings, and lectures of the Society (but not to promenades nor on reserved occasions), and to the Chiswick Gardens on two days, will be issued to *bona fide* gardeners recommended by two Fellows."

—NOTHING can be more graceful than the species of Tamarisk called *Tamarix plumosa*, which is still uncommon though easily propagated. Its numerous slender branchlets resemble the curled plumes of the ostrich. It flowers in August about the same time as *T. indica*. The flowers, which are disposed in dense erect panicles, have an airy lightness, which adds much to the elegance of the foliage. Isolated on a lawn, or in a large park, *T. plumosa* forms a compact mass of the most pleasing appearance. It is, according to the "Revue Horticole," quite as hardy as *T. indica*, and should be propagated and treated in precisely the same manner.

Cresses and their Improvement.—I find that the Curled Cress, if neglected, is liable to degenerate to the common sort; but, if properly treated, it is capable of being improved in a very high degree. This is effected by selecting, every spring, a number of the most perfectly curled plants as soon as they can be discovered, and pricking them out at 5 or 6 in. apart from each other, and at a distance from the common sort. The seed from these plants may be considered as stock seed, and from the plants of this seed should all the succeeding plants be annually selected, taking care, if possible, to make choice of those only which are more thickly curled than the stock from which they have been obtained. The Golden Cress is rather slenderer in growth than the common Cress. It is very dwarf, and is consequently short when out. It has a mild and delicate flavour, and affords a pleasant addition to our stock of small salads. It should be sown and managed in the same manner as the Curled Cress.—ALPHA.

WHERE is the grave of Sir Artur Kellyn?

Where may the grave of that good man be?

By the side of a spring on the breast of Helvellyn,

Under the twigs of a young Birch tree!

The Oak that in summer was sweet to hear,

And rustled its leaves in the fall of the year,

And whistled and roared in the winter alone,

Is gone—and the Birch in its stead is grown;

The knight's bones are dust,

And his good sword rust—

His soul is with the saints, I trust.

—COLFRIDGE.

THE FLOWER GARDEN.

THE BEST TREE PEONIES.

THE following list contains some of the very best varieties of tree Peonies or Moutans at present in cultivation; I obtained it from my friend M. Charles Verdier, of Paris, who makes Peonies his special study; among them, as will be seen, are few novelties, but M. Verdier states that the newer varieties are generally inferior to the older kinds:—Athlète, large, double, lilac; Bijou de Chusan, pure white; Carolina, bright salmon; Colonel Malcolm, violet; Comte de Flandres, very large, rose; Confucius, deep pink; Elisabeth, deep scarlet, very double; Farezzi, large, pale lilac striped with violet; Frangans maxima fl. pl., pale rose; Lambertine, blush rose petals,

Double-flowered Moutan.

tipped with violet; Louise Mouchelet, large double pink; Madame de Sainte-Rome, bright lilac-rose; Madame Stuart Low, bright salmon-red; Marie Ratier, large, rose; Odorata Maria, pale rose; Prince Troubetskoy, very large, double, deep lilac or violet; Purpurea, a deep amaranth, semi-double kind; Ranierii, bright amaranth; Rinzi, very large, bright rose; Rosini, a semi-double, brilliant rose-coloured variety; Rubra odorata plenissima, very large, double, lilac-rose; Souvenir de Madame Knorr, large, double blush; Triomphe de Malines, large, violet, a colour which deepens at the base of the petals; Triomphe de Vandermaelen, very large, and double violet-shaded rose; Vandermaelii, blush, almost white; and Van Houttei, large, double, carmine. Peonies are plants of easy culture, accom-

Single-flowered Moutan.

modating themselves to every description of soil; they are very hardy, abundant flowerers, and very varied in colour. The best time to plant Peonies, both tree and herbaceous, is September, and, if vigorous plants be selected they will readily produce a few blooms the following season, thereby gaining a year over those planted in spring. They succeed better in a heavy soil than in one which is dry and light. Before planting the ground should be deeply dug, as they have long tap-roots, and if well manured all the better; but the manure should be well decayed, as, if fresh, it has a tendency to generate rot Fungus. A shady airy situation is best for plants of a pale pink or yellowish hue, as bright sunshine injures their colours. In France tree Peonies are increased by means of root-grafting.

Versailles.

A. TRUFFAUT.

DOUBLE-FLOWERED POPPIES.

DOUBLE Poppies may be said to occupy the foremost rank among hardy annuals, so large and brilliant in hue are their flowers. They have, therefore, a most striking character, but are not nearly so much grown as they deserve to be, and it is probable a certain amount of prejudice may have been created against them on account of their unpleasant perfume and the shortness of the duration of their bloom, but their gorgeous colouring makes some amends for the comparatively short period during which they are in flower. The annexed engraving represents one of the best known Poppies, viz., *Papaver somniferum*, the double form of the Opium Poppy, which is so much grown in this country for its heads, they being extensively used for medicinal purposes. It generally grows about 2½ ft. in height, and varies in colour from white to deep crimson. The double scarlet, the double striped, and the double white are all varieties of this, and the flower-heads, being of great size, make a bold and striking effect when planted in masses. I have seen large beds of these double Poppies when in full bloom with the bright sunlight streaming down on them from an unclouded sky, and the effect was gorgeous in the extreme. By means of careful selection, a type of Poppy called the *Pæony-flowered* has been obtained from the foregoing, having large but very double broad-petalled flowers of various colours, from pure white to dark crimson. I remember on one occasion seeing some fine strains of this Poppy at the Dedham seed grounds of Messrs. Carter & Co., and it was a glorious sight. This is known in some seed lists as *Papaver pæoniæ-*

The Double Opium Poppy (*Papaver somniferum* fl. pl.).

florum, and is certainly distinct enough to represent a type. The new *Ranunculus* Poppy is a double form of *Papaver Rhœas* of Linnaeus, and is produced in varied colours; in this species the petals are more entire and rounded, and they reflex somewhat, hence the term *Ranunculus-flowered*. Like the foregoing types, this also has burst into a great number of colours, self and variegated. It is synonymous with the double form of the French Poppy of the seed catalogues, and is of dwarfer growth than either of the preceding. The German Poppies are the best representatives of the foregoing types, saved in colours, and sent to England in collections. Messrs. Carter & Co. state that their experience of Continental-saved Poppies points to the conclusion that varieties can be saved truer in England than on the Continent, and that is why they grow them in such large quantities in their seed-grounds. All these Poppies, being hardy annuals, can be sown where they are to bloom, but they should be grown in good soil in order to bring out in the fullest perfection their size and colour. The seed, being very small, should be sown thinly, and the plants eventually thinned out to 6 or 8 in. apart; this enables the lateral shoots to develop themselves, and allows of space for the flowers. In semi-wild places, and by the sides of drives, they can be made conspicuous features; and their cultivation is recommended to lovers of hardy border flowers. I know, indeed, of no other class of what may be called annual plants that will afford such a brilliant display as the different kinds of Poppy do in outlying beds and borders during the summer months. Viewed from a distance even their colours are strikingly effective.

Q.

PLANTS IN BLOOM AT HYÈRES.

The French have a saying that, "L'hiver expire aux pieds des Palmiers." If this be true, and from an experience of several winters I think it is so, it must at least be conceded that this year it dies hard, as the bitter winds and frosty nights of the last fortnight testify; but, when at Hyères, and sitting under the Palm trees or walking in the garden of the well-known firm of Messrs. Huber & Co., the sunny side of winter is certainly presented. The most striking thing under glass in this establishment is the array of Primulas for seed; just now these are in full beauty, and the intense colouring of the scarlet and magenta varieties must be seen to be appreciated. Some allowance must be made for the effect of the sun in the south of France, or disappointment may follow, as I know to my cost. The habit, shape, and size of the blooms are also excellent, and really seem superior to what I saw in Belgium, where much care and attention had been bestowed upon them. Among the striking objects in the garden are several tall columnar specimens of *Yucca filifera*, whose trunks are fully 3 ft. in circumference and 20 ft. in height. The beauty of some *Beaucarneas* and *Dasyliirions*, models of health and vigour, suggested that to see such specimens in their full magnificence they should not be cramped in pots, as generally seen in England. Just beyond this green mass a large bush of *Pyrus japonica* (one scarlet flame of bloom) and several *Acacias* (one mass of golden flowers) made an effect that puts to shame any ordinary bedding, be it subtropical or carpet, and with a brilliant sky and sun overhead gave a summer glow that made it hard to believe the accounts of severe frost and snow received from Paris. A fine specimen of *Latania borbonica* laden with clusters of blue berries also attracted attention, but it showed symptoms of having suffered from the cold. Elsewhere, near the Place des Palmiers, an army of old women were gathering Carnations to send to Paris, the tree varieties being grown largely for that purpose; the flowers at present are small, but bright in colour and very sweetly scented. Roses and Neapolitan Violets are conspicuous by their absence, as well as *Camellias*, thus presenting a great contrast to what is grown at Nice and Genoa. A large and beautiful public garden has just been made on the slope of the hill, which will in a few years greatly surpass the puny squares and public gardens at Nice and Cannes, unless the winds should make havoc of the tenderer shrubs planted there, and must add to the charm of this quiet little town. Several of the Palms, for which it is so justly celebrated, are of great beauty and considerable height, and the apricot-coloured stalks of the bunches of Dates glow among the pale sea-green leaves till each seems to lend to each a double charm. The Almond trees, also in full flower, make a tender harmony with the silvery Olive trees and blue sky, and complete our chord of winter-colouring.

E. H. WOODALL.

Nice.

EFFECTIVE MIXED FLOWER-BEDS.

In effect, nothing surpasses a bouquet of flowers well arranged, for in it we can combine the different shades of colour most effectively. It is the same with a mixed flower-bed, which permits the use of subjects that cannot be introduced anywhere else. As a rule, the geometrical flower garden does not admit of the employment of great variety in the way of colour. Mixed beds, that is, beds filled with a variety of the usual bedding plants, annuals, and biennials, &c., arranged with an eye to effect, have this advantage, that they may at any time be introduced into the geometrical garden, among other beds, or masses of colour, without violating the style; while in gardens of small size, where the beds are few, as in villa gardens, they afford room for variety that could not otherwise be found—that is, where the geometrical style is adhered to. Indeed, it is only under such circumstances that they are admissible, for it is obvious that, as flower gardens are at present arranged, a series of mixed beds would only produce that monotony which their introduction is intended to relieve. Mixed beds may consist of a combination of colours of many shades; and sometimes a very telling effect is produced by the construction of only two or three which blend well together. It is essential under all circumstances, however, that the plants employed should be nearly all of the same height, as any inequality in this respect destroys the effect to a great extent. The best examples we ever saw were two beds laid out in front of the windows of a mansion. They had been well managed, and were

much admired, yet the materials were few and simple. The beds were oval in shape, and, though the general effect was chaste and rich in the extreme, it could be seen that the most pleasing contrasts were due to the presence of purple and bright crimson German Stocks, Purple King Verbena, a few well-coloured *Coleus Verschaffelti*, *Calceolarias*, and scarlet and pink *Pelargoniums*, including a good proportion of *Mangles' Variegated*, planted judiciously on a groundwork of *Cerastium tomentosum*, which had been allowed to come into flower along with the other plants, the whole surrounded by a compact border of blue *Lobelia*. In such a bed the variegated *Alyssum* may be used in place of the *Cerastium*, only it is not so white, though more lasting. In order to bring the *Cerastium* into flower about the same time as the other plants, the earlier flowers should be shorn off, otherwise it will flower early in June. It should be planted in tufts, about 9 in. or 12 in. apart, and not so as to cover the whole surface of the bed, for most bedding plants thrive badly in a dense carpet of *Cerastium*, which reflects the heat and keeps the ground cold, besides robbing the surface of the soil with its numerous roots. It was allowed to encroach upon both sides of a strip of *Viola magnifica* here last season, but it so injured the *Viola* that it had to be cut back again and the *Viola* removed.

Another combination, which is unusually effective, is a mixture of *Mangles' variegated Geranium* and *Viola cornuta*. The *Viola* should be planted early in the season, say in March, and the *Mangles' (autumn-struck plants)* in June or earlier, in order to produce flowers soon. It is the mauve colour of the *Viola*, and the delicate pink of the *Geranium*, which are most telling. This *Geranium*, though one of the very oldest varieties we possess, still stands unrivalled; it is so freely variegated, and we have no light pink to match it. A good bed may be formed by using it for a groundwork, on which to dot, here and there, single plants of brilliant *Pelargoniums* and *Lobelias*, or, what is better than the latter, Purple King Verbena, or any of the good purple *Violas*. A good general combination may be made at any time by mixing judiciously a miscellaneous collection of bedding plants; such mixtures are handy for replenishing vases or for bouquets, as one can get all that is required at the same place. We plant a border of this kind every year near the house, using up all the varieties which are left after the general bedding is finished. For planting such a border the different species should be arranged in lines according to their heights, taking care to have all the colours in each line. Thus, the tallest *Geraniums*, *Verbenas*, *Calceolarias*, *Ageratums*, &c., and the *Verbena venosa* will form the black line, and in the next will come dwarfier plants of the same, with Stocks, Asters, *Mignonette*, *Alyssum*, and *Tagetes*, &c., terminating in the front lines with such things as *Lobelia*, *Alyssum*, *Gazania*, dwarf *Geraniums*, *Calceolarias*, Golden *Feverfew*, and whatever else may be available for the purpose. Such herbaceous plants as Carnations, *Phloxes*, *Anemones*, *Spiraeas*, *Dielytra spectabilis*, and a few more of the most effective kinds, may also be introduced with much advantage, or they may be the permanent occupants of the border, and the spaces between can be filled up in summer in the above manner. Be sure to plant thick enough, however, so that there may be a good show during the summer and autumn months.—"Field."

[In addition to the above style of bed with mixtures of plants of nearly the same size, various other kinds of great beauty may be made, either of many plants varying greatly in height, or of dwarf and tall plants. In fact, it is quite possible to make a garden wholly of mixed beds (if that were thought desirable), and yet have no monotony resulting, for each bed might be wholly distinct from its neighbour. Mixtures of bold subjects, such as *Cannas* and *Dahlias*, are very satisfactory when well done. Slender growers, too, like *Gladoli*, starting from a mass of low-growing plants, may also be made very beautiful. In fact, the improvement that may be worked in this direction is limitless.]

EARLY CROCUSES AND OTHER SPRING FLOWERS.

CROCUS AUREUS is now in full flower in my grounds at Tooting; the peculiarity of this species is that it blooms before the foliage appears. Among varieties of the Cloth of Gold Crocus, one named *Retii aritextus* has short foliage and a dwarf compact growth; the outside of its petals is conspicuously coloured crimson-black. Another, under the name of *stellatus*, is larger in all its proportions. Of the Scotch Crocus there are several varieties, of which the one ordinarily sold has the outer petals striped, and the inner ones pure white. Another variety, under the name of *argenteus*, stands midway between the one just described and *Crocus Imperati*; its outside petals are fawn, striped brown; the inner petals pale lavender. A third, the *C. biflorus* of Parkinson, is similar to the one called *argenteus*, but smaller in all its parts. *Crocus stellaris*, a Dutchman's name for a rich deep yellow variety, has its outer petals striped with crimson-brown. *Crocus sulphureus striatus*

sulphur, striped with crimson-brown, is similar to *stellaris* but much paler. *Narcissus* (*Corbularia*) *monophylla* is now in flower. Am I the first to have bloomed this in England? It is a little gem of the purest white. Among other plants in flower are—*Leucojum vernum*, *Hepaticas* (red and blue), and *Iris reticulata* var. *Krelagei*—this is the purple-red variety figured in the "Botanical Magazine."—P. BARR.

THE FETID HELLEBORE.

This well-known old-fashioned plant is one of those whose charms do not secure them a place in borders of hardy flowers, and yet it

Helleborus fetidus.

is too good to be ignored altogether. In very small gardens it has few claims to a place, but in large ones those who cast it out may some day find themselves admiring a graceful tuft of it in a cove or shrubbery in early spring, at which period it is most attractive. The best place for it generally is in semi-wild or rough places near to or in the pleasure ground, or in smaller gardens in the shrubbery. It is scarcely necessary to add that the odour is very offensive from broken portions of the shoots—another reason for allotting it a place among the wildlings.

THE FEATHER GRASS.

This very elegant Grass is a well-known, but still not a very common plant. The genus to which it belongs contains many varieties, all of which are more or less interesting or ornamental, but not one of them approaches in elegance or beauty the *Stipa pennata*. Though sometimes said to be British, it is, in reality, a native of the south of Europe, where, owing to the vast quantities of it imported in a dried state, it must be grown largely. After all it is only when gathered, and the awns collected in bundles, that its beauty is seen, bunches of it almost equalling in beauty the tail-feathers of the Bird of Para-

Feather Grass (*Stipa pennata*).

dise. I have for many years used the awns of this Grass to give a finish to vases or baskets of flowers in the following manner:—I procure a quantity of stout Wheat straws, stiff and unbroken, cut them into lengths, say, of a foot or so, and into one end of these little straw cylinders I insert from six to ten of the feathery awns of the *Stipa*, in a radiating direction. I thrust the straws thus changed with awns pretty freely into vases or baskets of cut flowers until the straw is quite hidden, when the silvery awns, rising out of and waving above the flowers with which they are associated, add a grace and a charm to such floral arrangements that few could imagine. As regards culture nothing need be said, as it will grow in any soil or situation.

THOS. WILLIAMS.

EARLY HARDY FLOWERS.

NATURE is now beginning to feel the quickening influences of mild weather, and our earlier spring flowers are pushing up their welcome blossoms. The Snowdrop, the lovely blue Siberian Squill, the rich golden Crocus, the pale Primrose, the Violet, Wallflower, and other early flowers are fast bursting into bloom, and if no sudden blighting influences of frost and biting winds intervene, an early spring is likely to be the result. Of late years in gardens there has grown up a taste for what is known as spring flower gardening; a taste that has been developed out of the system of bedding out tender plants, in order to obtain a brilliant display of colour in summer; but which system simply left our gardens mere blanks, as far as flowers were concerned, for more than half of the year. To remedy this, some have adopted the plan of filling their beds and borders with hardy plants, that flower early in the year, and admit of being removed in time for the usual tender plants to be put out at the end of May. At Cliveden and Belvoir, spring gardening shows all that it is possible for skill and glass-houses to accomplish in that way. Both beds and borders are alive with beautiful hardy flowers, and words are inadequate to express the effect thus brought out. It is obvious, too, that what can be done so well in a large way can also be done well in a small way, and there is not a villa or cottage garden in the country that might not be radiant with floral beauty all through the early months of the year—especially April and May—provided the right material be obtained, and properly adapted. The double Daisy, for instance, yields several striking and effective colours, and produces bright masses. They are cheap, easily propagated, and only need removal to some cool spot for the summer, to make them available for next year's use. In the Daisy we have white, pink, red, and crimson hues, and also some mottled forms, but one of the most pleasing of all the Daisy family is the pretty crimson flowered kind, that has golden-blotched foliage, and which, even without flower, assists to render a garden cheerful during the dull winter months. There are also variegated Daisies, having pink and white flowers, but these are as yet somewhat scarce. Pansies also constitute another important class of decorative plants. Among these we have blues, whites, yellows, purples, maroons, and even blacks, as well as various other intermediate hues or mixtures, such as are found in the old Magpie, a pretty Pansy, having blotches of white on a purple ground. Pansies and *Violas* may be got fairly true from seed, but propagated plants of such distinct kinds as Cliveden Yellow, Yellow Boy, White Swan, Blue King, Blue Bell, Cliveden Blue, Cliveden Purple, Violet King, and many others, will give rich and defined masses of colour that will continue for a long period. Pansies are easily propagated by means of cuttings or by dividing the old plants. Primroses, both single and double, and Polyanthus also furnish beautiful decorative material. The double Primrose includes about ten colours, but of these many are scarce. The commoner ones are the white, lilac, and sulphur, and these are pretty for small beds or as edgings to larger ones. Single Primroses now furnish myriads of colours, and good bedding sorts, white, sulphur, rose, red, purple, and crimson, are obtainable, and many of these are extremely beautiful; indeed, the finest-named forms of the single Primrose deservedly take the pride of place as the most beautiful of all hardy spring flowers. The white and primrose-coloured and crimson Polyanthus are also remarkably early, and yield rich masses of colour. A bed of white polyanthus, edged with a blue Pansy or crimson Daisy, produces a truly charming effect. Another great favourite is the beautiful early Forget-me-not, the *Myosotis dissitiflora*, which flowers from the middle of March to the end of April, and gives one of the loveliest masses of cerulean blue conceivable in flowers. This is at least a month earlier than the common kind. *M. sylvatica* is generally grown with the pink *Silene pendula*. These two plants, however, although they yield pretty and effective masses of colour, are seldom at their best until May. Wallflowers, especially the rich crimson and the dwarf yellow, are easily raised from seed, and if not used in beds are very effective in borders. These are but a few of the plants that are available for spring flower gardening, and where used judiciously produce the most charming effects. Where bulbs, such as Tulips, Hyacinths, &c., are used, it is a good plan to plant the bed after the bulbs are put in with dwarf-growing plants such as a bed of red Daisies with white Tulips, or white Daisies under blue or red Hyacinths. In this way, and with a liberal use of Crocuses, Snowdrops, and Scillas planted in patches or in lines here and there, bulbs can play an important part in any well-arranged garden, and materially assist in producing a beautiful display during early spring.—A. D.

Some New Delphiniums.—What great improvements have been worked amongst Delphiniums during the past few years! A bed of them finely flowered is a striking object in its rich hues of blue.

The double and single forms alike have been subject to the change^s and the long huge symmetrical closely-set spikes are objects of great beauty. Among the double flowers the following, according to the "Florist," are particularly fine:—Argus, azure-blue, striped and tipped with rose; Claire Contrant, bright azure-blue; Grandiflorum plenum, rich dark shining blue, tinted with bronzy-red, large and fine; Herman Stenger, outer petals bright violet-blue, centre petals rosy-pink; Keteleeri, a distinct and beautiful variety, producing freely dense spikes of lavender-blue flowers; Paul et Virginie, outer petals bright blue, centre petals bronzy-red, striped and edged with white; Roi Léopold, outer petals bright blue, inner petals rosy-violet, centre sulphur and white; and Thiers, azure-blue, centre white and rosy-pink. Of the single flowers, which after all are the most striking, the following are effective:—Ambale, azure-blue, changing to rosy-lilac white and orange centre; Celestial, ultramarine-blue, with conspicuous velvety-brown centre; Formosum lilacinum, light lavender tipped with pink, ornamented white centre; La Belle Alliance, bright violet-blue, with a white and orange centre; Madame Chaté, porcelain-blue, suffused with bronzy-red, orange and white centre; Madame Henri Jacotot, bright azure-blue, suffused with delicate rosy-pink; and Pulcherrimum, rich shining blue, changing to reddish-bronze, orange and white centre.

Blue Hydrangeas.—I have struck several cuttings from the common pink Hydrangea, which have produced beautiful blue flowers. This may be effected by means of a little powdered alum being mixed up with the soil in which they are grown. Now is a good time for putting in the cuttings, which I find do best when plunged in a little bottom-heat, as they make good blooming plants for planting out in about two months' time. The Hydrangea is not only useful for planting out; it has also a striking appearance in window boxes and window vases for house decoration.—T. W.

A New Way of Striking Pinks and Carnations.—Twelve months ago, when I went to pipe my Pinks, I put each sort after dressing them into a pot with water, the pipings being packed close together; these I placed under a bush until I got my bed ready.—By accident I omitted to plant one lot, and left this in the pot.—I did not see them for some three weeks or more, and when I came to look at them they were all rooted. I at once took them and planted them in the stock-bed and did not lose a plant. This year I adopted the same plan with all my Pinks; only, instead of putting them in the shade I put them in the sun. They struck without a single failure, and no one can have finer plants.—"Florist."

Columbines in Utah.—The Columbines of the Rocky Mountains are very desirable plants for garden purposes, the gem of them all being *Aquilegia cœrulea*. This has now been introduced for some time, but some plants of this species seen in Utah seem to belong to a distinct variety; their colour is not blue or blue and white, but pure white or yellowish-white. They were flowering in great quantity 10,000 ft. above the sea, wherever any tiny stream trickled down the mountain slopes, and the flowers at a little distance reminded one more of those of *Eucharis amazonica* than anything else. The plant grows in handsome tufts 2 or 3 ft. high, the flowers large and broad, and the spurs very long (2 in. at least), with a rounded knob at the top.—M.

Plants and Ozone.—Professor Mantogazza, of Pavia, has lately discovered that ozone is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinth, Mignonette, Heliotrope, Lemon, Mint, Lavender, Narcissus, Cherry-laurel, and the like, all throw off ozone largely on exposure to the sun's rays. So powerful is this great atmospheric purifier, that it is the belief of chemists that whole districts can be redeemed from the deadly malaria which infests them, by simply covering them with aromatic vegetation. The bearing of this upon plant culture in our cities is also important.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Garden Edgings.—Can you suggest anything besides Box for the edgings of walks? Surely there is some other plant that would stand cutting and would look better.—ЕДНЪЮВЪК. [None with which we are acquainted.]

The Fraxinella.—I find this to succeed better when fully exposed to the sun, and in a situation well manured I have had twenty-five flower-spikes on a plant. It may be transplanted at almost any time. Its scent is agreeable; but it is as well to remember that it is a poisonous plant.—F.

Fern Leaves for Beds.—In most parts of the country there are woods which are full of Ferns that usually are of little use, save as a gratification to the sense of sight. It may be worth knowing, therefore, that the soft parts, if stripped from the stems and dried in the sun, retain their toughness and elasticity for a long time, and are said to be superior to straw or chaff, and even better substances than these for stuffing mattresses. The ticks, when filled, should be stitched firmly with a mattress-needle, using strong linen twine.—E.

TREES AND SHRUBS.

LEBANON AND ITS CEDARS.

SINCE I sent you some notes on the Cedar of Lebanon (see p. 56) I have found a communication by Dr. Hooker, dated 1861. According to this letter, Mr. Jessup, an American missionary, had discovered several extensive groves of Cedars in Lebanon. Of these there are five, three of great extent, east of 'Ain Zahâleth, in the southern Lebanon. One grove lately contained 10,000 trees, and had been purchased by a barbarous Sheikh from the more barbarous Turkish Government, for the purpose of trying to extract pitch from the wood. The experiment, of course, failed, and the Sheikh was ruined, but several thousand trees were destroyed in the attempt. One of the trees was 15 ft. in diameter. Two small groves were found on the eastern slope of Lebanon, overlooking the Buka'a, above El Medék; and two other large groves, containing many thousand trees, one above El Barûk and another near Ma'asiv, where the trees are very large: all are being destroyed for firewood. The Rev. Mr. Tristram had also discovered another grove, and another was discovered near Dûma, making in all ten distinct localities to the south of the one originally discovered. The accompanying sketch gives some idea of the appearance of these Cedars in their native habitats.

W. B. H.

Transplanting Large Trees in Summer.—Two of the largest trees, which, in all my operations in that way for the last forty-five years, have ever been attempted to be removed, were successfully transplanted at Kingswood Warren, Surrey, the seat of Sir John Hartopp, Bart. They were two Cedars of Lebanon of the following dimensions:—The first was removed in the middle of July, 1875, in an active state of growth, with an undisturbed ball of earth, weighing over 40 tons; its height was 50 ft., the diameter of its branches 37 ft., feathered to the ground, and the girth of the trunk was 8 ft. 10½ in. The second was removed the first week in August, also in an active state of growth, with a ball undisturbed, over 50 tons in weight; it was 18 ft. long, 15 ft. 6 in. wide, and 3 ft. 7½ in. deep. This tree was 47 ft. in height, 69 ft. in diameter of branches, 11 ft. 6 in. in girth of trunk, and at 4 ft. 8 in. above ground it measured 10 ft. 0 in. in circumference. This tree was raised up an inclined plane, and in the first 101 ft. from the starting point was raised 7 ft. 9½ in. Both of these trees rested on large baulks of timber, and were moved on rollers. These trees have never shown any check, and are now in vigorous health. The sub-soil, being a concrete mixture of flints and marl, with clay, was no doubt favourable for the ball holding together, but, on the other hand, was most difficult to drill under.—WM. BARRON, *Elvaston Nurseries, Borrowash.*

Lifting Effect of Frost on Trees.—Dr. Lapham, State botanist and geologist of Wisconsin, says that frost exerts a lifting power on full-grown trees, so as to induce an impression that the tree begins to grow again after once attaining its full growth. When the land freezes expansion ensues, drawing the tree up with it, and leaving of course a cavity whence the root was drawn. When the first thaw comes, the moisture, carrying earthy matter, enters the cavity, and thus the root is prevented from returning to its original position. Dr. Lapham suggests that one of the chief objects of the tap-root may be to guard the tree as much as possible against this frost-lifting.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Gum Tree in Derbyshire.—Let the "Derbyshire Grower" try his Gum tree in the way suggested by Colonel Leigh in *THE GARDEN*, with a thick carpet of hair round its roots. That will give it a chance.—B. [Colonel Leigh's plan is a good one for many plants that fear cold at the root, but no substitute for the climate required to develop a Gum tree freely. Even those in the south of England and Ireland, where the climate is mild, never assume their true character from the want of sufficient heat.—E.]

The Virginian Cedar in Winter.—The Red Cedar, when it grows in natural luxuriance, is sometimes loaded with beautiful purple berries, which massed among its dark evergreen foliage, present an exceedingly ornamental appearance. By selecting the berry-bearing trees in their wild localities, a strikingly ornamental effect might be produced.—J. J. THOMAS.

Anderson's Oak (Quercus Andersoni), a new species of Oak from the Sikkim Himalayas, was the subject of a paper read by Dr. King at a late meeting of the Linnean Society. It is the "Katoos" of the Nepalese, and one of the very finest of Indian forest trees. It is closely related to *Q. speciosa*, but is met with at higher altitudes, and will probably prove a valuable tree for our gardens and woodlands.

CEDRARS OF LEBANON AT HOME.

THE FRUIT GARDEN.

FALLACIES IN FRUIT CULTURE.

PRACTICE based upon extreme ideas when applied to gardening matters, as in the case of most other things, is rarely sound. It often owes its origin to insufficient knowledge possessed by the individual with whom it originates on the subject with which he endeavours to deal. It might be supposed that appliances and methods of cultivation thus ingeniously foisted on the public would quickly die a natural death; but such is by no means the case, for it often happens that for a time at least they are endowed with a vitality that well-nigh defies the clearest proof of their worthlessness, for no matter how glaring their inconsistency may be, or how clearly they are shown to be useless, they rise again hydra-like. Some twenty years ago the wonderful discovery was made that growers were all wrong in cultivating hardy fruit in the open air according to the system that had been found to succeed thoroughly for the preceding generation at least. Trees large and small in the open air were to be superseded by a race of Lilliputians grown in pots under glass. The cultivation of Peaches, Nectarines, Apricots, Cherries, Plums, Pears, and Apples was to be completely revolutionized by the new discovery. Old gardeners, with perceptions as clear and observation as keen as any that are likely to follow them, and who moreover had the great advantage of leisure to devote their attention to hardy fruits in a way denied to gardeners of the present day who have so much to divide their attention, shook their heads when they calculated the cost in labour and house accommodation. Some had the temerity to express their dissent or to hint that the fruit could not by any possibility be worth the cost incurred in labour, however abundant the crop proportionate to the size of the trees. But their remonstrance was summarily dismissed, and whoever did not fall in with the new idea was unceremoniously put down as hopelessly incapable. Edition after edition of the treatise that described and belauded the system was published, the result of which was that by amateurs innumerable who were fond of the pursuit, and in many larger establishments, often against the better judgment of the gardener, the system was adopted, and the little toy trees found purchasers by the thousand, the only difficulty being to keep pace with the demand. Hundreds of fine old productive Apple and Pear trees were consigned to the fire as encumbrances not longer to be tolerated. Even the flowers of these miniature trees were discovered to have a beauty about them such as the stupidity of the practitioners of the old school had never allowed them to discern in trees grown naturally in the open air. Nothing could possibly have been more satisfactory than the movement was on one side, *i.e.*, the sale of the trees; but not so on the other, for the chagrin and disappointment experienced after a time was complete, and just what was patent it would be to any man experienced in fruit culture, backed by common sense. When the little-tree mania began to subside, they might be seen in all directions thrust into out-of-the-way corners, and looking about as comfortable as drone bees do when expelled the hive by the workers. The fact was that those who had been deluded into spending money for trees, and erecting houses wherein to grow them, found out to their cost what every one possessing ordinary powers of calculation, and practically acquainted with fruit culture, were certain of when first the method was brought under notice. But the game is not yet quite played out with these little pot trees. In another quarter it was discovered that the means of giving them often a complete change from the inside of a house to the open air would be an advantage. To effect this, a movable platform, covering the greater portion of the floor of the house, was invented on which to place the pots; it was mounted on wheels running upon metals in the form of a railway, which was continued outside the house, the end of which was made to open, and in this way run out and in. Even yet a treatise on this method of fruit-growing is advertised, with an intimation that the system is in operation at Chiswick. True, the house spoken of is there, but it is not in working order. The whole of this little-pot system of fruit growing, with its root cramping and shoot pinching, has just turned out to be what

all not open to adopt every new-fangled crotchet that is prepared to extract money from their pockets from the first could see it would be.

And now from one extreme we jump at a bound right to another, that is, if we are to follow the last new doctrine enunciated by Mr. Shirley Hibberd in his paper upon "Hardy Fruit Culture," read the other evening at the Society of Arts, and which has been given more or less in detail in the different gardening papers. The wholly unrestricted system that Mr. Hibberd advocates is the very Antipodes of the pot method, and is undoubtedly vastly more natural, but, like any other practice when carried out indiscriminately under all conditions of soil and situation with every plant or family of plants in cultivation, it is a mistake. There is no occupation that it is possible to be engaged in wherein it is so imperative that the practice should be varied according to the widely different conditions that surround the subjects to be operated upon as gardening, taking it collectively, and hardy fruit culture is no exception to the rule. Any indiscriminate method of cultivation that can be laid down for growing any description of fruit or fruits, under the widely different conditions of soil and situation, as well as the varied means and requirements of individuals, is as impossible to succeed as is the single nostrum with which the itinerant medical practitioner professes to cure all the bodily ills that affect humanity. His reference made to Oak and Elm trees is a most unhappy one, and completely beside the mark, as they are grown for the wood they make, which is very different from the production of fruit. The free slightly restricted forms of Apple and Pear trees Mr. Hibberd advocates are perfectly right for orchard culture in the majority of situations, but certainly not for all. In the thousands of acres occupied by market gardeners near large towns where land is dear and the soil well suited for vegetable growing, trees, restricted to a medium size, say 10 or 12 ft. in height, are found preferable; these do not obstruct the growth of culinary vegetables in the way that large trees do. But it is evidently not to orchard culture of these fruits that Mr. Hibberd directs his attention, or he would have said so; besides, in them he has no ground for complaint on the score of restriction, as there are few who cultivate Apples and Pears on a large scale in orchards, who are so blind to their own interests as to restrict the growth of their trees further than is necessary to keep them sufficiently open for the admission of sun and air, and the consequent production of full-sized handsome fruit. It is, therefore, clearly the management of these fruits in ordinary gardens to which Mr. Hibberd directs his remarks. And here I join issue with him, and maintain that in nine cases out of ten such trees as I have above alluded to are in every way preferable to such as are allowed to assume their full natural dimensions. Even in the largest gardens Apple, Pear, and other fruit trees grown to their full size are highly objectionable; they prevent the possibility of growing anything satisfactorily near or for a considerable distance round them, and they do very serious damage by shutting out sun and air from such crops as are far removed, from being overhung by their branches, and are in like manner injurious to the trees that occupy the walls. Whereas, if trees be managed so as to allow of their growing to a medium size they are better in every way; they do little harm to anything that is not absolutely planted on the space overhung by their branches; they are more manageable as regards gathering the fruit; the latter is not only larger, finer coloured, and consequently better flavoured through the additional light and air which it receives than that produced on the inner branches of large unpruned trees, but there is also another and a very important advantage attached to those trees that are confined to the size I have mentioned above, *viz.*, the bearing branches soon acquire a thickness and size very much greater than the bearing wood of unpruned trees, and are thus enabled to resist wind in a way that prevents the fruit being blown off to anything like the extent that takes place in the case of unpruned trees. This is of much more importance in private establishments, such as those with which Mr. Hibberd is dealing, where the fruit has to be kept, than it is in the case of those who grow for market, and who generally dispose of their produce as soon as it is fit

for use, and still further, in small gardens it is often advisable to keep the trees smaller than the 10 or 12 ft. high I have named. Mr. Hibberd's teaching is perfectly sound as regards giving the preference to large Peach and Nectarine trees over small ones; but, in the next breath, he cuts the ground from under his feet by advocating 6 ft. high movable wooden walls. Does he mean to say that anything but the smallest of small Peach trees can be grown on these? How is he going to confine them within the space available, especially as he denounces (and correctly) too much reduction of the leaves in summer. He will have no resource left but yearly taking up and cutting the roots, a plan which he equally condemns. I am no prophet, yet I venture to predict that the produce of these movable walls will never pay interest upon capital expended in their erection, to say nothing about depreciation and labour. They are in every way fitting companions for the Potato tiles, which unquestionably were the very worst horticultural appliances ever seriously put before the gardening public. I usually derive much pleasure from the productions of Mr. Hibberd's pen. They possess an originality about them that is refreshing; but in these Society of Arts' papers he has blundered.

The dwarfing Apple stocks that have of late been a good deal noticed, are spoken of as something new, yet they are only very old friends resuscitated. I well recollect when a boy, in the gardens at Cloughton Hall, forty-five years ago, in the borders on the sides of the walks in the kitchen garden there were quantities of them, or what we at that time knew as the French Paradise stock, and which, if not identically the same, was not perceptibly different from the Pommier de Paradis, or Doucin, at present talked about. But let not those who have not an intimate knowledge of the capabilities of this stock in different soils recommend it indiscriminately, as, at Cloughton, although the soil was a deep strong loam, and hundreds of other places, it very soon died out; the trees were healthy for a time, and looked well when about the size of good Currant bushes and laden with fruit, in many cases that would have outweighed the trees that bore it. These dwarfing stocks will live in a soil that is naturally well suited to Apple culture; but where it is not, especially if at all too dry, they are useless, being affected similarly to the Quince stock for Pears under like conditions. The cultivation of hardy fruits is one of the most important branches in gardening, and in order to acquire a fair knowledge of the subject, it is necessary to be both fond of it and to give much more study and time to it than many would seem to think requisite, judging by the indiscriminate way in which it is frequently treated.

T. BAINES.

[Notwithstanding Mr. Baines' denunciation of orchard-house trees, we feel bound to caution our readers against too summarily discarding their culture. No doubt merits were claimed for this system which it does not possess; but, nevertheless, we are bound to record the fact that there are now in this

country many examples of the most profitable results from it. We would also remind Mr. Baines, who speaks as a gardener of long experience and great skill, that other growers of long experience and great skill in fruit culture, such as Mr. Peter Grieve, Mr. Tillery, Mr. Douglas, Mr. G. F. Wilson, Mr. Pearson, and many others whom we need not mention, grow trees in this manner with the most satisfactory results. In saying this we have no desire to recommend that in all cases trees in pots should replace the beautiful and fertile tree that one sees planted out in Peach-houses, &c., in so many good gardens throughout the country, and from which the finest fruit is annually gathered in abundance. No other system with which we are at present acquainted could surpass that for large gardens, but it is beyond all question that the orchard-house system, well managed, is a very excellent one, and a great gain to those who wish to obtain a variety of fruit from small structures.—Ed.]

A Dwarf Apple Tree on the Paradise stock.

DWARF APPLES.

For summer and autumn sorts, dwarf Apples are valuable in affording a home supply. They begin to bear in two or three years from planting, and at five or six years, if well cultivated, will afford a bushel or so to each tree. A portion of a garden as large as the tenth of an acre may be planted with forty or fifty trees, without crowding. All the different varieties of the Apple may be made dwarfs by grafting on the Paradise or Doucin stock—the former are smaller and bear sooner; the latter are larger and ultimately afford the heaviest crops.—“Rural Affairs.”

NOTES ON ORCHARD-HOUSE CULTURE.

My experience with all sorts of fruit-trees, except Cherries in orchard-houses, has extended over a period of nearly ten years. Watering the trees—all of which are in pots—at the busiest season of the year is a serious matter, and when water has been scarce, and our labour-power taxed to the utmost, I have often wished that the trees had been planted out; but the most serious obstacle in the way of this is, that the house must then be almost entirely devoted to the trees; a few flowering plants might be introduced amongst them, but not to any advantage. As to having portable houses, if it could be managed without an annual expense for skilled labour, it would be a great boon; but as only a small per-centage of orchard-house is on that principle, we must do the best we can with the houses which we have. The largest pots which we use are 15 in. in diameter, inside measure; 17-in. pots were tried, but they were found too heavy for one man to move, and the advantage gained was not compensated by the extra labour. My orchard-house culture may be summarised in a few words. The trees are taken into the house on the first day of the year, at least the Peaches and Nectarines; Pears and Plums are still out-of-doors. The pots are pretty well saturated with water, and unless it is necessary to apply artificial heat to keep out frost, they will not require any water for three weeks or more. We have not room to get in the Pear and Plum trees, else they also would be under cover. The Peaches and Nectarines are brought in as the trees are more tender. They must be looked over about once in a week, and all requiring water should have a good supply. No more than this is required until the blossoms begin to expand, when about eleven o'clock every morning the

branches must be shaken sufficiently to distribute the pollen; at this time I admit air freely and leave the ventilators open a little at night if the weather is mild. If, at this stage of growth, the weather is dull and cold, the heating apparatus should be used, if there is one. When the fruit has set it will probably be necessary to thin out more than three parts of it at first, reserving about twice as many as will be required for a crop; it is not good management to leave the fruit on longer than it is necessary to do so, for even in the very early stages of its existence the small fruit must exhaust the resources of the tree, being formed almost as soon as the leaves. When the trees are healthy and under good management the fruit may all be thinned out long before the stoning period, after which the house should be kept close and moist, shutting quite close as early in the afternoon as possible, so that the temperature may rise to 85°: the night temperature may be 65° or 70°. As the ripening period approaches the temperature must be lowered, more air admitted, and less moisture given; previous to this the trees should have been syringed twice a day, but as the fruit ripens syringing must also be discontinued. When the fruit has been gathered, such trees as require it are re-potted, but those that were potted the year previous are this season only surface-dressed. A tree turned out of a 15-in. pot is very frequently re-potted in one of the same size; when this is done the roots must be very much cut back, but the trees (although the leaves may flag a little for the first day or two) do not suffer. The house is kept a little closer at the time of potting and surface-dressing. The trees are turned out-of-doors a few weeks after they have been re-potted, and as soon as they are out the house is filled with *Chrysanthemums* and other seasonable flowering plants, which make a splendid display for more than two months. Besides the other fruit trees there are shelves for Strawberry plants in pots, which yield a supply of good fruit before that out-of-doors is ripe. As regards Peaches I consider the following six to be the best for orchard-house culture:—Early York, Royal George, Grosse Mignonne, Bellegarde, Barrington, and Exquisite; the two last are rather shy setters, but, with a little attention at flowering time, such as a camel-hair pencil drawn over the flowers, they will set well enough. I have named Exquisite, as it is the best of the yellow-fleshed sorts, and should be grown for variety. The best Nectarines are—and, like the Peaches, they are named in the order of their ripening:—Lord Napier, Erluge, Violette Hâtive, Stanwick Erluge, Pine-apple, and Victoria.—J. DOUGLAS, in "Florist."

White Scale on Pine-apples.—I shall be obliged to any one who will kindly advise me as to how I can destroy white scale on Pines.—PINE, *Hardenberg Sæskjøbing, Denmark*. [Try Mr. Tillery's cure for the white scale. It consists in "mixing equal quantities of the driest new soot and flowers of sulphur together, and syringing the plants with a fine syringe, then dusting them above and below with a common sulphur puff." This is the only cure confidently recommended, but we may state that we have known the most energetic means taken to destroy the scale have no effect, though the plants appeared to be clean for a short time, the scale returned with returning growth, and spread with amazing rapidity; and in the end the stock had to be burnt, the house washed and scalded, and the brickwork thoroughly washed with hot lime, put on with a brush and soaked well into the crevices. Dipping the plants in water of a temperature of 132°, and in a strong solution of soap-suds for several hours has also been recommended, and "Pine" might try the experiment on a plant or two first, but we have little or no faith in such remedies.—J. S. W.]

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Fruit Trees for the Northern Sides and Walls of Gardens (Dorset).—Pears—Doyenné d'Été, Jargonelle. Ickworth Impératrice Plum, Coe's Late Red, Denyar's Victoria, Early Prolific. Cherries, Currants, and Gooseberries for late use.

Labels for Wall Trees.—Amongst the many inventions for this purpose, there are few that have stood the "test of time" better than those composed of soft sheet lead with the name of the tree stamped on them. If nailed firmly to the wall when the tree is planted, they will be found as legible after fifty years' service as on the day on which they were fixed. They enjoy perfect immunity from the action of the elements, and may be pronounced indestructible.—J. Gnoott, *Wenhams*.

Fruit Trees left to Nature.—I am somewhat amused to find Mr. Hibberd clamouring for Nature to have her own way with our fruit trees, considering that the very neglect he advocates causes half the orchards of England to produce fruit not worth sending to market. Let him go through any of our Apple-growing counties, and he will be satisfied indeed. Even as he speaks along in the train he will see how thoroughly his system has been observed; one thing, however, he will not find anywhere—an unpruned orchard that produces fruit of the best quality.—W. T.

PLATE IX.

THE CRIMSON-ANTHERED LILY.

(LILIUM SZOVITSIANUM.)

Drawn by H. HYDE.

THE fine Lily, of which the annexed is a representation, is a native of the Caucasus and adjoining regions, and was introduced into British gardens at the beginning of the present century. It was figured in the "Botanical Magazine" as far back as 1811, from a plant which flowered in Messrs. Loddiges' nursery at Hackney. In the Edinburgh Botanic Garden I first observed it in flower about the year 1836. Plants of it must have been raised from seed received from the late Dr. Fischer, of St. Petersburg, a frequent contributor of Caucasian seeds to the Edinburgh Garden about fifty years ago. Two varieties of it have been long cultivated here under the names of *Lilium monadelphum* and *L. monadelphum speciosum*. The flowers of the latter were of a pale cream-colour, more or less spotted, having dark orange-brown pollen on the large anthers; while *L. monadelphum*, also a cream-coloured kind, had a slight yellowish tint throughout, and numerous minute spots on the petals, and the pollen of a light yellow colour. It is fortunate that this Lily is so easily produced from seed, as it forms very few bulblets, no matter how long it may remain in one situation. Some cultivated in a border have been in the position they now occupy undisturbed for fourteen or fifteen years, and yet they rarely ever produce more than one spike. Plants of it are readily produced from root scales, a system which is taken advantage of by many cultivators, and is the only method of increasing and keeping pure any really good or marked variety. Seed, however, is the readiest way of acquiring a stock of this truly charming plant. We have several beds of it in various parts of the garden, all the plants in which were originally raised from seed, and although the seed-bearing plants flowered beside many other garden species, it is a remarkable fact that no hybrid varieties are to be seen amongst them. If hybridisation takes place, it is only between the original varieties, as in some cases they are growing close to each other. The only difference observable in the seedling is in the colour of the pollen, which varies in different examples, running from the pale yellow through every intermediate shade to the darkest orange-brown. In some of the plants the petals are revolute, and vary from cream colour to a light yellow, more or less spotted. All, however, seem to be slight intermediate varieties between the original *L. monadelphum* and *L. m. speciosum*. We have several beds of this Lily, each containing some hundred bulbs, their flowers being annually used for class purposes; and, although these beds are lifted every four or five years, comparatively few of the plants ever produce more than one shoot. The plants average from 3 to 5 ft. in height, the tallest in general bearing the finest flowers. The finest flowering specimens vary from 3 to 4 ft., and it is not uncommon to count on such plants fifteen or eighteen blooms. The number of seedlings now cultivated being large and their differences minute, we call them all *Lilium monadelphum*, notwithstanding that the name implies a union of the stamens; some of the plants, indeed, are truly monadelphous, while in a large proportion of them the stamens are free, and some are exactly intermediate between the united and free condition. Besides the figure given in the "Botanical Magazine," under the name of *Lilium monadelphum*, a figure of the same plant is also to be seen in Paxton's "Magazine of Botany," in which it is named *L. Loddigesianum*. Of the species figured none of the flowers come up to the size of those produced here, where each bloom with its revolute petals measuring from 3 to 3½ in. across, and from 5 to 5½ in. from one point of a petal to another. This plant was first named *L. monadelphum* by Bieberstein in his account of the Caucasian Flora, and I am inclined to adhere to Bieberstein's name in preference to that of *L. Szovitzianum*.

The soil in which it is generally grown here is sandy loam, manured only during the operation of re-planting. Although a large collection of Lilies is cultivated here, none requires less attention than the one under notice, which, when seen in bloom in large numbers, is really a gorgeous sight. Every flower

produces a seed-vessel, erect in form and of a greenish colour, having reddish-brown markings throughout, and in this condition they have rather a peculiar appearance. When ripe they assume a yellow-papery hue and open at the top, from whence thousands of seeds may be annually saved. The seeds are usually sown in large shallow pans or flats, where they generally remain for two years; by this time the bulbs have attained some considerable size; they are then planted in beds in rows 6 in. apart, and 4 in. bulb from bulb, re-planting when necessary. By this treatment flowers are frequently produced by seedling plants four or five years from the time of sowing.

Royal Botanic Garden, Edinburgh.

JAMES McNAB.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Indoor Plants.—Most kinds of hard-wooded stove plants now require potting; any of the deciduous species that have been freely cut back whilst at rest should be potted before the young shoots that have broken make much growth. This is especially the case with plants that have to be partially shaken out, as where this is done the inevitable mutilation of the roots will cause much of the young growth to stop if allowed to get too long before potting. As previously recommended, before potting the soil should be placed where it will get as warm as the internal temperature of the house where the plants are to be grown. This holds good with subjects of all descriptions, but more particularly with those grown in a hothouse. See that the soil, whether peat or loam, be in a proper condition as to moisture when used, being careful not to use it too wet, as it is impossible for the roots ever to enter it freely when compressed too closely in a wet state. The proper conditions of the soil as to moisture when used will be clearly arrived at by compressing tightly in the hand as much as can be held, and then laying the handful down on the potting-bench; if too wet, the mass will remain intact; if it contain no more than the requisite amount of moisture, it will crumble slightly; but in all cases, amateurs, in their first attempts at plant-potting, will do well to keep the soil for all kinds of plants rather too dry than too wet. The much larger quantity of water required by stove subjects through the growing season than the occupants of the greenhouse necessitates the soil being used in what may be most easily described as a rough, lumpy state—pulling it in pieces by hand, and never sifting it except for newly-struck cuttings. After potting do not give any water for some days, until the roots have had a little time to heal. It is a very common practice with beginners at plant-potting to leave the soil too light in the pots; when water is applied in this state it holds too much, and the roots, especially of hard-wooded subjects, are, in consequence, seldom produced in sufficient quantities; it also tends to the formation of soft spongy wood, with a less disposition to flower. To avoid this, as the soil is filled in the pots round the ball, it should be rammed down with a stout lath, being careful not to break the roots; do not fill the pots too full, as this gives much more trouble when watering, through there not being space sufficient to admit of the whole being moistened without filling up two or three times, which is frequently the cause of the lower portion of the soil in the pots getting into a dry hard condition, which prevents the roots making healthy progress. It will generally be found the best to pot the largest plants first, when these have to be moved into larger-sized pots, as it will liberate theirs for the smaller stock, in all cases washing the pots thoroughly, and allowing them a short time to dry before using; dirty pots can be washed much easier, and they will dry fit for use in a few minutes if the water be hot. Plants, such as *Allamandas*, *Bougainvillias*, and climbing *Clerodendrons*, that are grown on trellises, should have these fixed to the pots by three or four stout sticks being thrust well down into the soil, fastening the trellises to them with this wire that will not rot through the moist atmosphere of the stove, like bast or twine. It will be easily understood that by inserting these sticks in the new soil, mutilation of the roots will be avoided that would otherwise occur if they were not fixed till the roots had made more progress.

Bedding Plants.—It is now time to get on with striking bedding plants, as, if this work be delayed, the young plants have not time to acquire sufficient strength and size, with the requisite hardiness, before the time for planting out arrives, the result of which is that the season is far advanced before they get well-established, and in a condition to flower freely. Those who have the convenience of a stove may dispense with the usual hot-bed and frames for cutting, striking, and also with propagating glasses and cutting-pots, by using small pans or saucers, such as are used under some pot plants. This is the method known as striking in sand and water, which is a

very simple process, but one that I find is often misunderstood, leading to failure or only partial success through the sand being merely kept in a damp state, instead of sand and water. The pans used for this purpose should not be very deep, for, if there be too much water over the sand, soft-leaved cuttings, such as *Verbenas* and *Lobelias*, are liable to rot. Small pans, 1½ in. in depth, are the best; put in them 1 in. of clean sand in the bottom, and add as much water as will completely cover it, filling the pans up to the brim, in which state they must be kept until the cuttings are rooted, filling them up, as the water diminishes, by soaking through the pans, and by evaporation. When there is not enough water, soft cuttings flag, and either do not root at all, or very slowly. The principle of the method is to dispense with confining the atmosphere that surrounds the cuttings by the use of propagating frames or glasses ordinarily employed, which the use of the water supplants. The advantages are that where a stove is at command, and there is not an extraordinary number of plants to be struck, the usual appliances can be dispensed with, and the cuttings can be placed on shelves so near the light that they do not get drawn up weak whilst making roots, and do not need shading except when the sun is directly upon them. Care must be taken that the leaves of the cuttings are not bruised in the least, and that they are not allowed to flag by an insufficiency of water over the sand. They should also be potted off or placed in boxes as soon as they are rooted. By this method *Verbenas*, *Ageratum*s, *Fuchsias*, *Lobelias*, *Calceolarias*, and *Heliotropes* will root in ten days or a fortnight. A prejudice often exists against using pit sand for cutting-striking, especially when it is of a reddish colour, under the impression that it is impregnated with iron; yet it frequently happens that for striking cuttings of soft things such as the above, it will answer quite as well as the best white silver sand, but it will generally be found that in using this pit sand, the cuttings will root much quicker in it when first dug than after it has remained for a time exposed to the air.

Pits and Frames.—Soil for using in Cucumber and early Melon beds should be put in an open and airy shed, and frequently turned over so as to dry it sufficiently; if put on the beds when too wet it causes so much vapour as to make the young plants extremely tender and liable to injury from the least sun. If it be laid quite thin, and on a dry surface, when under cover, it will be in a fit condition for use much sooner. As the days get longer, give plenty of air to everything in frames that will bear it, especially *Cauliflower* and *Lettuce*; draw the lights completely off on mild days, without which they become weakly; when grown under hand-lights or cloches, treat similarly.

Apricots.—These should now be pruned and nailed or tied in according to the system on which they are grown. If this work be delayed too long, the buds that have swollen to a considerable size are liable to be knocked off in the operation.

Peaches that were loosened from the walls in the autumn with a view to retarding their blooming may remain a week or two longer before being pruned and nailed if their buds are yet backward. As the state they are in will depend much upon the part of the kingdom and local conditions of soil and situation, no positive time for doing this work can be laid down, but the longer the trees are kept away from close contact with the wall the later they will flower with a proportionately better chance of their escaping frost. It is good practice to prune the whole first and defer the nailing or tying as late as it can be done without injury to the bloom.

Planting.—All planting of everything of a deciduous nature should be brought to a close as soon as possible; as, after this time, removal seriously interferes with the season's growth, especially if the weather during the ensuing month be cold, accompanied by drying winds.

Stoves.

With lengthening days affording an increase of sun and light, the temperature may now be gradually raised. Anything ranging from 55° to 65° will be ample during the night, affording an increase of from 10° to 20° on the afternoons of bright sunny days. During dull cold weather the heat must be kept low, as it is useless attempting to force on growth in the absence of light. The same with night temperatures; it is useless battling with the weather, endeavouring to maintain a certain degree of heat, as much more harm is done in that way than if the thermometer were now and then allowed to run back 5° or 10° in severe weather. The ungenial state of the atmosphere caused by overheated pipes is far more detrimental to the health of plants than an occasional decrease in the temperature, provided that does not go beyond a certain limit. On sunny days the pipes should be kept as cool as possible, so as to obviate the necessity of opening the ventilators beyond what is necessary in the ordinary way of just changing the air to promote healthy growth.

Anything beyond this is mere waste of fuel and injurious to the plants, as every particle of moisture is driven out, leaving them in a flaccid exhausted state from the rapid unfavourable change the air undergoes when this occurs. The fires, therefore, in all plant-houses should be kept sufficiently low to prevent any extra heat in the pipes till towards mid-day, and then to make up for the absence of sun; but the latter and fire-heat together during the forenoon should at all times be avoided. It is impossible to maintain plants in health and keep them free from insects if care and attention be not exercised. The importance of so regulating artificial and natural heat cannot be too strongly impressed on beginners and others inexperienced in such matters. Most stove plants will now require re-potting, not so much to get them into larger pots as to renew the soil, that will, in most cases, have lost its fibre and porosity, or have become exhausted or stale through continuous watering. All young growing stock should at once be shifted on, using good rough fibry soil, which should consist principally of peat and loam mixed in the proportions of about two of the latter to one of the former. This, with a little sand, will suit the requirements of most stove plants, excepting such as Anthuriums and others of that class that want rough lumps of peat and Sphagnum. No stove should be without these most useful and attractive plants, as they are so very easily grown. Their flower-spathe are as curious as they are brilliant and beautiful, and last for a great length of time on the plant; or when cut and used for the flower vase, and associated with the Eucharis or other light flowers of that class, they are especially effective. The pots for these should be well drained, as they require large supplies of water while making their growth, and a small pot placed in an inverted position in the bottom of the one to receive the plant, which should then be filled to a third of its depth with pieces of soft, porous brick, charcoal, or potsherd, on which should be placed the rough peat and Sphagnum for the plant to grow in. Keep it well up above the rim of the pot, so that when finished off the crown of the plant may be elevated at least 2 in. Work the rough lumps of fibry peat carefully amongst the large fleshy roots, so as not to bruise or injure their soft spongy tips; and when doing so, fill in the interstices with fresh Sphagnum and an occasional lump of charcoal the size of a Walnut. Keep the leaves well sponged and the plant heavily syringed while making its growth.

Marantas and Caladiums.—These are ornamental and useful plants for decorating the conservatory, halls, or corridors, in the summer or autumn, or for mixing with Ferns and other fine-foliated plants. None are more beautiful or useful for the above purpose than the old *M. zebrina*, and as it will grow in a lower temperature than most of the others, it is doubly valuable. *M. Veitchii* is a splendid variety, having rich markings, and is a fit companion to the above. These should now be planted in a rich, loose, vegetable soil, consisting principally of peat and well-rotted leaf-soil, with a few small lumps of fibry loam and a very little decayed manure and sand. Pot moderately loose in well-drained pots, which should be of rather large size to give them plenty of root-room. Give them a little bottom-heat to start them, or place them in a warm part of the house where they can have frequent syringing or a moist atmosphere. Marantas are shade-loving plants, and must, therefore, not be placed where the sun shines fully on them. Roof climbers, such as *Allamandas*, *Bougainvillias*, and others of that class, should now be pruned in, and the former regulated and tied. With regard to *Bougainvillias*, it is only the variety known as *glabra* that admits of being pruned at this season, as the others flower on last year's wood; and, therefore, to remove any of this is to take away a portion of the bloom. In cases, however, where they have been allowed to become thick and crowded, it may be desirable to thin out some of the strongest shoots that are not showing flower freely, as that will let in light and air to the others, which is highly essential for the purpose of imparting the natural colour to the numerous leaf-bracts. The young wood of *glabra* will flower at almost every point if it be kept properly thinned out while growing, and if successful when planted out, it may be had in bloom from May to October, or even later. *Bougainvillias* require very close watching just now, as green fly is sure to attack them, and by lodging themselves in the young embryo bracts, they are apt to escape notice. In addition to crippling the tender growth, they greatly disfigure the delicately-coloured leaves by their excreta, and this cannot be removed by syringing. To ensure perfect freedom from these, the plants should at once be slightly fumigated, repeating the operations for two or three days in succession. Syringe frequently to dislodge any that may remain, as well as to promote free growth and a full development of the plant's rich inflorescence. Start *Caladium* bulbs by placing the store pots in a much warmer position than that in which they have been wintered. The top of hot-water pipes is a suitable place for them; or for convenience, and to economise room

they may be shaken out of the old soil and be started by placing several bulbs in a pot or pan, to be plunged in a good brisk heat. If any water be given, it must be in the most sparing manner possible, or the bulbs will rot. Unless the soil becomes exceedingly dry, it is seldom that they require watering till the bulbs begin to push, and even then what is afforded by syringing is generally sufficient, as bulbs of this description contain sufficient moisture in themselves to start them into growth. Allow them to become well advanced before any attempt is made to increase them, for if divided by cutting the bulbs through before they have made some roots and tops, they are almost sure to rot. The most useful and distinct varieties to grow are *Argyrites*, *Bellemei*, *Alfred Blea*, *Dr. Lindley*, and *Prince Albert Edward*. The latter is a very distinct kind, and valuable on account of its stout leaf-stems, that are almost as stiff as those of an *Alcassia*, standing well erect without any support; *Argyrites* is a perfect little gem, its size and habit rendering it most suitable for table decoration; *Gloxinias* may be started in much the same way, and receive similar treatment to that recommended for *Caladium* bulbs. Any of these now starting should be potted in rough peaty soil in the pots it is desired to flower them in; place them on shelves well up to the light, but not in a position where the sun strikes them with full force; water most sparingly till they get well into leaf and firm hold of the new soil, after which water liberally. For late autumn blooming seed should be sown at once, the produce from which is sure to give many beautiful varieties, often equalling some of those named. Sow on the surface of finely-sifted peaty soil and cover the top of the pot or pan with glass, shading it during the day till the seeds germinate. A brisk bottom-heat will soon bring them up, when they must be placed near the light to keep them from drawing; prick out as soon as large enough to handle, and grow them quickly on in moist heat. Plants of these raised now and pushed forward in this way will be most useful for late blooming, and afford a good stock of strong bulbs for another year. *Achimenes*, on account of their great variety and general suitability for decorative purposes, can scarcely be had in too great a quantity. These do best started in fine peat or sifted leaf-soil, from which they can be easily separated, after having formed shoots an inch long, which is a good length for transferring them to their flowering pots, or starting them in baskets, for which latter purpose they are well adapted on account of their pendulous habit. A loose, rough, peaty soil is the most suited to their requirements, as it remains open and porous, thereby affording a free passage for water, of which they require large quantities when carrying their bloom. Place those already potted into a nice moist heat where they can be frequently syringed; a vinery, or other forcing-house at work, will be just the place for them, provided they are not too far from the glass.

Plants for the Sub-Tropical Garden.

The sowing of such subjects as *Wigandia*, *Acacia lophantha*, *Udhea*, *Solanum*, *Canna*, *Centaurea*, and others that take a long time to grow to get them of sufficient size, should be commenced at once, postponing to a later period such as *Castor Oil*, *Chilian Beet*, *Zeas*, *Amarantus*, &c. The latter, if sown early, are sure to get stunted and checked in their growth, and are always much inferior to those plants raised in April, when the weather favours a quick healthy growth. Start any old roots of *Cannas*, but, before doing so, shake out the old soil and divide the roots, to afford room for new growth. Any frame with a slight bottom-heat will answer the purpose for starting them in. Scatter some rotten leaf-soil amongst them, from which they will lift with good balls of earth without suffering any check whatever. Treated in this way, the time and labour of potting is saved, and they can be kept in a much smaller compass. *Aralia papyrifera* is, perhaps, the most effective of all the fine-foliated plants now used for an out-door display during the summer months. Where these have been wintered in cellars or sheds, or other out-of-the-way places, so as to have caused the loss of their leaves, they should now be started under glass if an early display be desired; pieces of the large fleshy roots of these cut up in lengths of 2 to 3 in., and placed in bottom-heat, will soon break, and form nice plants for the outer margin of beds containing others of larger size.

Ficus elastica is a most serviceable plant for the sub-tropical garden, from which if lifted in the autumn it becomes valuable for the greenhouse or for halls, corridors, or rooms, in positions where it would be unsafe to put plants of a less hardy and enduring nature. Cuttings of these strike readily at this season, or where numbers are desired, they may be increased at a more rapid rate by inserting buds with a leaf attached to each. The leaves must be kept erect by supporting them with a small stick or two as required. Young plants of from 1 to 2 ft. high with single stems, having leaves from top to bottom, are the most useful and ornamental. Buds or cuttings inserted now will develop into healthy subjects by next winter.

Hedychium Gardnerianum is a most attractive plant, and quite as hardy as a *Canna*, with which it associates well on account of being of similar habit. These should now be divided and started into growth preparatory to being turned out in May, which should be done in rich soil to induce them to flower freely. If lifted in the autumn just before they show bloom, they will be found valuable for the greenhouse, where they will last a long time in beauty, and attract much notice from the singularity of their flower-heads. Those not required for the above purpose may be left in the ground, where they will stand the winter if protected with a little mulching of some kind, such as half-rotten leaves.

Greenhouse Ferns.

These should now be closely examined to see if any turtle scale, thrips, or other insects, are lurking on the fronds. If so, the present is a good time to clean them thoroughly, as some of the old fronds may now be removed, and so save the time and trouble of hand-washing. The practice of entirely denuding them of their fronds at this time of year is bad, and has a very weakening effect on the plants. In cutting them away, judgment and care should be exercised, first removing such as are ripe and becoming shabby and discoloured, and gradually following on with the others as the young fronds unfold. By a strict adherence to this course, the plants receive no check, as there is then always a sufficiency of leaf to keep up healthy root-action. Any tree Ferns that are too tall for the positions assigned them may have their stems shortened to the desired length, and be re-planted in the same position. This is an operation that can be carried out with the greatest safety at almost any time during the winter, and before they begin to make young fronds, and is also a great advantage to such rapid-growing plants as tree Ferns, which soon get too large and high for an ordinary-sized house; but with the above treatment they can be kept within bounds, and in the same positions as long as it is thought desirable. After shortening the stems, a good portion of the old fronds should be removed, only leaving two or three to assist in the formation of fresh roots. If the stems be bare of these, they should be bound up with Moss to keep them from the light, and in a uniform state of moisture. Re-plant in good rough soil, containing a third of broken brick of an open porous nature, that water, of which tree Ferns require large quantities, may pass quickly and freely through. Keep them syringed freely overhead and about the trunk, but the soil should only be slightly moist till they begin to root freely into it. These, as well as the stove varieties, will now require potting, for which purpose the same kind of soil as recommended for the stove kinds will answer, only that most of these, especially such as have thick fleshy fronds, will be benefited by a larger admixture of loam. Where these are planted out and grown in the natural style, the soil that should have been kept somewhat dry during the winter should now have a thorough watering, so as to ensure the whole of it being moistened; but before doing so, see that the soil has not shrunk away from the sides of the rock, or become loose and hollow from settling; if so, thoroughly fill up the interstices with fresh soil before applying the water. On bright sunny days give a gentle syringing, but merely exclude frost by night, so as not to hurry them on, unless a different course is rendered necessary by the house containing kinds that will not stand so low a temperature. Sponge and clean the leaves of Palms and other broad-foliaged plants, that they may present a bright healthy appearance, and not contrast unfavourably with the Ferns. These are rather subject to white scale, especially if in a rather dry atmosphere, or at all pinched or starved at the roots, either from being pot-bound or kept in too dry a state. Such objectionable pests must be got off by hard rubbing, but it must be done with care, not scratching or defacing the plants. A half worn-out toothbrush is, perhaps, the best for the purpose, and from four to six ounces of Fowler's Insecticide to a gallon of water will not be too strong an application, as the plants will suffer no injury from it at that strength, provided it does not lie and soak into the hearts of the plants. Where fresh soil cannot be added to the roots of these in sufficient quantity to prevent them from becoming in the above unsatisfactory condition, they must be assisted by frequent applications of weak manure-water made from soot and guano.—J. SHEPPARD, *Woolverstone Park*.

Orchids.

Peat, Sphagnum, carefully washed sandstone, grit, and crocks, may now be got ready for potting purposes. All pots, pans, &c., may be washed in wet or dull weather, and labels prepared for future use. At present but little can be done in the way of potting that cannot be better effected next month. Do not water too copiously at the roots in dull weather, but maintain a humid atmosphere, especially when the weather is dry. The extreme dryness of the air in plant houses, and especially in those which are artificially heated, is

an evil which cannot be too carefully guarded against, as it is one which has a baneful influence on all plants, robbing the tissues of their proper juices, and thus weakening them for their future growth and bloom. Some plants now making growth, such as *Odontogloss*, *Dissas*, *Oncidium macraethum*, and some *Masdevallias*, may be more copiously watered than pseudo-bulbous species which are now at rest, but no Orchids should be allowed to become absolutely dry at the roots, if we except the deciduous *Calanthes* and *Dendrobis*. All shrivelling of either bulbs or foliage must be carefully avoided by keeping the compost uniformly moist. One of the best tests of the humidity of the compost and air of the Orchid-house is living *Sphagnum Moss*, which should be used as a surfacing to all pots and pans in which cool Orchids are growing; it answers the purpose of a hygrometer, and preserves an equable temperature and genial moisture around the roots. *Dissas*, *Cypripediums*, and *Masdevallias* may receive a gentle dewing during bright weather in the forenoon with advantage, and air should be given at every available opportunity during mild weather. Orchids in bloom should be carefully attended to, and moisture should be regularly supplied at the roots so as to counteract that tendency which the bulbs and foliage have to shrivel when placed in the dry atmosphere of the conservatory or show compartment. In some cases where the plants are rather weakly, they produce too many flowers, and in that case it is an excellent plan to cut some of the spikes or flowers as they open so as to relieve the plants, and enable them to start better into growth than if their energies had nearly all been expended on flowers alone. *Phalaenopsis* and some *Masdevallias*, more especially the chaste little *M. tovarensis*, are very apt to bear an enormous quantity of flowers, and if these be all allowed to remain, the health, if not the very existence, of the plants is endangered. Some of the warm-growing *Dendrobis* will now be showing signs of young growth, and it is an excellent plan to hang such plants near the light in one of the early vineries. Some of the finest plants of *D. Devonianum*, *D. Wardianum*, and *D. Pierardii* I ever saw were grown in this manner, and a sunny vivary affords an excellent climate in which to ripen off pseudo-bulbous *Dendrobis*, *Laelias*, and *Lycastes* during the autumn months.—B.

Hardy Herbaceous Flowers and Alpine Plants.

At this season of the year every fine day should be turned to account by an inspection of Alpine plants whether on rockery or in frames. On the rockery many of the choice and smaller-growing sorts will have become disinterested by the dying away of their summer's growth, and in not a few instances will choice gems have succumbed altogether. Many of them will, however, have fought their battle for life valiantly, though, in most cases, against great odds, under the adjacent shadow. At the present time the smaller plants of the rockery should be moved to a more advantageous position for their future development, or transplanted to their proper home—the "wild garden," where they will have every opportunity of putting their full energies to the test. This applies especially to plants grown on rockeries which have been made a couple of years or more, and in which the amateur from want of a practical knowledge of the varying developmental powers of such plants, is sure to find that some do not prove a success in that position, while others again assume a more luxuriant growth than was originally calculated on by the horticulturist, to the detriment of the less favoured plants; for instance, it is not the amateur alone that is liable to make mistakes in the arrangement of his rock plants; the professional cultivator will occasionally fail. This arises from the variation in the vigour of growth which many plants assume under different conditions and in different localities; a plant may be only a few inches high, and yet when established will in a single summer cover a square yard of rockery, to the disparagement and injury of all its surroundings. Such subjects as these should be relegated to a fitting place by themselves; take, for example, the *Oenothera taraxacifolia*, *macrocarpa*, and *eximia*, the latter more popularly known as *marginata*—these are all charming rock plants, but require an abundance of elbow-room; in fact, the last-mentioned species appears to be a perfect vagrant, ignoring after the second year its paternal home altogether. Others, such as the variegated *Ground Ivy*, after retaining its true golden character for a twelve-month, will revert to its original green, and defy every attempt at limitation—that is a fitting plant for banishment to the wild garden, removing the roots and soil thoroughly, for every bit of stem will grow. A nice prepared compost should be used as the basis on which that portion of the rockery is to be rebuilt, and in which more appropriate occupants may at once be planted, using a good firm hand in the process. A similar soil, composed of loam, leaf-mould, and peat, with a free mixture of sharp sand, may be used as a top-dressing for the rockery generally. Many of the smaller-rooting plants will be found lifted up by the

frost, and these should be pressed firmly down again in the process of dressing, always having a few nodules of gritty limestone or sandstone to assist this operation. All the Androsaces, most of the small crustaceous Saxifrages, the Drabas, and smaller Primulas, and many others, are much benefited by being firmly wedged between lumps of stone. Where Alpines are cultivated in frames under glass, though too early yet to give them a general overhaul in the way of potting, for which process the middle of March will be sufficiently early, some of the early bloomers will appreciate a top-dressing of good rich soil, such as the Primulas, the Soldanellas, the various species of Corydalis, and even the Scillas and all early-flowering bulbs, provided, of course, they have not been potted in the autumn, which is the proper time; not that this is necessary every year, as my experience leads me to consider every third year quite sufficient. Bulbs, as a rule, do not like too frequent disturbance. The best enriching compost for this purpose is finely-powdered charcoal, previously placed in a barrel or large flower-pot, saturated with strong liquid manure, the fertilising elements of which it will retain long after it has become perfectly dry. On a bright sunny day, a thorough examination of all the pots in a frame will be of great advantage, thereby enabling the grower to detect and remove any portion indicative of damp before this mischief has become serious. This is of special importance after the frames have been closed and covered up for several days during frosty weather; it also presents a good opportunity for destroying those pests, the slugs, which are generally found under the projecting rim of the pot, or nesting beneath the tufty growth of any spreading plant; these do an incalculable amount of mischief in the dormant state of the plant, as they will eat out the buds, which means the complete destruction of both leaves and flowers. Where frame accommodation is abundant, it would be wisest to dress over the ashes of an empty one with fresh-slaked quicklime and soot, spreading a thin layer of fine ashes over the top to prevent the pots adhering to it and thus blocking up the drainage—removing the plants thereto.

Herbaceous Borders will require, equally with the rockery, an overhauling, and here we would recommend as an excellent plan that a memorandum should be made during summer of any of the occupants that require to be removed. Some that may have answered their position admirably for a couple of years, will by the third have acquired a development beyond all bounds, as the *Ferula* and many of the charmingly-leaved Umbelliferous plants, which are now pushing their spring leaves vigorously, and ought to be removed without delay. But, in doing so, remember that it is no light task, as their thick roots will be found to have penetrated even the roughest clay to a depth of from 2 to 3 ft., and are as brittle as glass; if much damage occur in the removal, a young seedling plant will make more rapid progress than the old stump, and in planting these, and all like strong-growing plants, forethought should be exercised, to avoid the necessity of any subsequent removal. During frosty weather a nice dressing of short well-decayed manure should be put on the border, distributed by means of a fork so as not to cover up the crowns of the plants. Frosty weather suits this operation for two reasons, as it enables the borders to be freely and cleanly walked upon, and, what is still more important, it subjects the manure, which contains a large amount of insect life, to its beneficial action, whereby myriads of insects are destroyed. About digging and stirring the ground all I shall at present say is—don't do so yet; content yourself with the manure-dressing till my next.—JAS. C. NIVEN, *Botanic Gardens, Hull.*

Kitchen Garden.

The sharp frost, snow, and rain of the last fortnight will, in some instances, have hindered the sowing of Parsnips and Onions; advantage must, therefore, be taken of the first fine day to get them in, though, if the ground be at all "pasty," it will be better to defer sowing for some time longer, rather than risk the loss of both seed and labour, through an unsuitable seed-bed. In order to succeed those already in frames, a small quantity of each of the following should be sown at the foot of a south wall as soon as practicable, viz.:—Lettuce, Brussels Sprouts, Savoys, Coleworts, Early London, and Autumn Giant Cauliflower; by sowing a pinch of the latter at intervals of a fortnight up to the beginning of May, a constant succession of fine heads may be secured till Christmas. This is the most valuable vegetable of recent introduction, and makes a regular succession of Cauliflower and Broccoli a matter of certainty. Sow Leeks, Parsley, and a succession of Peas as soon as circumstances permit; on heavy soils, Parsley should have the driest position, or much disappointment may ensue by its dying off in the autumn and winter; Lettuce plants that have been wintered in frames, or those that have withstood the weather in the open seed-beds, may now be planted out in any narrow border or small space between Gooseberry or other fruit bushes. Cabbages may at any time be transplanted from

autumn-sown stocks, and if they can be obtained in sufficient quantity plant near enough together, that alternate plants may be pulled out and used as Coleworts, when sufficiently large. A row of Cauliflowers may be risked out to succeed those under hand-lights. Dig a trench the same as for Celery, and deep enough to allow of a good layer of stable-litter in the bottom to afford a slight warmth, cover with 12 in. of soil, lifting them with good balls of earth round the roots; if the weather be severe, protect them by laying over the trench Spruce, Laurel, and Birch branches. In this manner Cauliflower may be had considerably earlier than from the open borders, and in many places this vegetable is so highly prized, that the extra labour should not be considered. It will now be safe to remove a part of the mulching from the stools of Globe Artichokes that are to be lifted, divided, and replanted, replacing the mulching as soon as the operation is finished: great depth of soil and abundance of head-room is necessary for the successful culture of this vegetable. Asparagus-beds should now be "pointed" over, in doing which care must be taken not to fork so deeply as to injure the crowns that will now be starting into growth; apply a dressing of salt over the entire surface of the beds, and the rain will wash its manurial properties down to the roots. Ground should now be in preparation for new plantations of Asparagus, which cannot well be too rich or too deep, and, being a marine plant, brine, salt, and seaweed are the most suitable manures for it, though it by no means refuses to thrive when other fertilisers are given. Earth up Peas soon, as they are well through the ground. Our own practice, at this stage, if the weather be frosty or very cold, is to draw the soil entirely over them. Those in earlier stages of growth should be staked, and on the windward side protected by supplementing the usual Pea stakes with evergreen branches. Cabbages and Broad Beans will also be the better for keeping the soil well up to the stems, besides the benefit accruing to the crops by the stirring of the land. Parsnips will soon begin to grow, and therefore ought to be taken up and housed in a cool shed, where they will keep good for weeks if layered in sand; moreover, the ground they have occupied can then be got ready by trenching or digging, and will be in good order for Scarlet Runners, French Beans, or Cauliflowers. Celery also, that manifests any tendency to run to seed, may be checked by lifting it with good balls of earth, and heeling it in in a cool aspect; the ground is then at liberty to be prepared for successive sowings of Peas, &c. In dry weather, if time can be spared for the purpose, keep the hoe at work amongst growing crops of Spinach, late Broccoli, and Onions; and, when wet, point rods for runner Beans and Pea-sticks, sorting them in sizes to suit the heights of each variety. In the forcing department see that nothing is injured by the too common neglect of airing when the sun is at all powerful; draw the lights quite off Potatoes, Cauliflower, Radishes, and Asparagus, that the soil may get the full benefit of the sun, closing sufficiently early to husband the warmth imparted. Seedlings of various kinds, that have been previously recommended to be sown in heat, should be pricked off betimes, as even the commonest vegetable will not bear a check without resenting it in some form or other. Keep up a constant supply of herbs and small saladings by sowing or planting such as are in demand at frequent intervals.—W. WILD-SMITH.

The Neil Prize.—At a meeting of the managers of the Royal Caledonian Horticultural Society, held on the 11th inst., the Neil Prize of £54 was unanimously awarded to Mr. Robert Foulis, gardener to G. H. Henderson, Esq., Fordell, Fifehire. Many of our readers may know nothing about the Neil Prize, and we may, therefore, state that the late Mr. Patrick Neil, of Canonmills Cottage, left £500, the interest of which was to be allowed to accumulate, and every three years to be given to some distinguished botanist or gardener. We have no doubt that the men to whom these prizes are given are worthy of them, but we should like to hear of them being given occasionally, at all events, to men whose work has benefited their profession or the country generally.

Collomia Seed and the Microscope.—I have received from a friend (says a correspondent of "Science Gossip") a few seeds of *Collomia*, concerning which he gave me the following directions how to obtain a most curious sight:—"Having obtained your seeds, take a sharp pocket-knife, and cut off as small a quantity as possible of the outer skin, then place it upon your fluid slide, and cover it with a small square glass slip; at first use your 1-inch object-glass, and it looks like a small piece of mud; but directly you put the smallest quantity of water in at the top of the slip, so as to touch the seed, myriads of spiracles will start away from it, and continue so to do for nearly ten minutes. I have tried this experiment a great many times, and always with success."

THE INDOOR GARDEN.

INARCHING FUCHSIAS.

THE best subjects for inarching are strong-growing kinds planted out as pillar plants in conservatories or as roof-climbers in plant-houses or in corridors. When the shoots from plants that have been out back close in winter have attained about 1 ft. in length, select the required number of young autumn-struck plants that have been grown on in heat—those in small pots with single stems are best—then fasten the pot in a convenient position for inarching the young plant on to the strongest shoots of the stock in exactly the same manner as is done in the case of Vines, viz., by paring off a portion of both stock and scion, fitting them exactly at the edges, and binding them tightly together with soft matting until a union is effected. They should then be gradually loosened and severed from the stock, a partial shading being beneficial to prevent flagging if the weather be very hot. The leading shoots of the stock should all be stopped in order to confine the growth to the grafts, which will make rapid progress, and by the end of the summer will bear quantities of bloom. The stock should consist of a robust-growing kind, the young shoots of which are much better adapted for operating on than those of slender growth. Of course sorts of opposite habit and colour should be chosen for contrast and the many beautiful variegated-leaved varieties may be used in this way with advantage. Although I have only referred to Fuchsias permanently planted out under glass, inarching is equally satisfactory in the case of plants in pots. Standards with umbrella-shaped heads are very effective fringed with sorts different both in leaf and flower from the stock. When small plants are not available, the end of the scion may be inserted in small bottles of water tied on the stock, which will keep the graft fresh until a union has taken place.

JAMES GROOM.

Henham.

THE CALABASH.

I HAVE in my possession a fruit which I have always understood to be that of the Calabash. It was brought by a relative of mine

some twenty or more years ago from the West Indies, and, although it has somewhat the appearance of a Gourd, its shape is much more beautiful. As described (see p. 124) it is very hard, and would make a capital water-bottle; in fact, one would think that Nature intended it for that purpose. I have more than once tried to grow its seed, which I have extracted from the neck of the fruit, but have been unsuccessful, although it looks perfectly good. The fruit, of which the accompanying is a representation, is light mahogany in colour, and bears quite a high polish. Its size is about 9 in. long and 4½ in. in diameter.

HENRY ROBINSON.

Oxford.

THE AMHERSTIA NOBILIS IN INDIA.

ALTHOUGH Burmah is the only country—so far as we know—where the *Amherstia nobilis* has been found growing—not in a state of wildness, but of abandoned cultivation—the rarity of the tree, even there, is almost proverbial amongst the residents; and it is very little known to the natives of the land, who, however, call it *Athauka*,* and regard it as the female of *Jonesia*, with which it is sometimes associated in the gardens of their kingoms. The late Rev. Dr. Mason, who probably was the best authority on the subject, assured me that the home of the *Amherstia* was still a mystery, and that the tree had never been observed very far from Kogoon, in Martaban, where it was first discovered by Mr. Crawford in 1826, and subsequently seen by Wallich, who named and

* Vide Dr. Mason's "Burmah."

described it in his "*Plantæ Asiaticæ Rariores*." Dr. Mason informed me also that the Rev. Mr. Parish had passed a specimen while descending the Yunselon River rapidly in a boat, and, in consequence, threw out the suggestion that it might be indigenous to that locality; "but," said Dr. Mason, "if that were the case, the Kareens would be familiar with it, whereas neither they nor the Shans, to whom the tree was shown in our gardens, recognise it." He added, "I have been myself up to Kareene without meeting with it, and even in cultivation it is not often seen." Although, perhaps, for wealth and blaze of gorgeous colour, this superb tree cannot be compared with *Poinciana regia*, *Salmalia malabarica*, the scarlet *Rhododendron*, or many of the species of *Erythrina*, yet in rich and graceful beauty it is absolutely without a rival, whether we regard the elegance of its noble pinnate foliage, or the airy loveliness of its long, pendulous racemes of brilliant flowers; and the enthusiastic delight of Wallich, when he first beheld it, can be very easily imagined. It appears to thrive well enough in Burmah, but still it is doubtful if even the climate of that country suits it perfectly, for it seems to be most difficult to propagate; and I was informed by the talented and experienced observer before quoted that it never fruited well, and that the large legumes which it produced were often barren, or nearly so—a single mature seed being frequently the sole occupant of one pod. I could not discover, with any degree of certainty, whether the seeds germinated readily or not in Burmah; but Dr. Mason told me that both General Blake and the Rev. Mr. Parish had sent them repeatedly to India, and in no case was the attempt to grow them there successful. With the exception of the trees in the Botanic Gardens at Calcutta, which were greatly damaged by the terrible cyclone of 1864, and one small plant in the Lal Baug at Bangalore, I never saw the *Amherstia* in India; and, even in Burmah, very few examples came under my observation. Three years ago I knew of four only in Rangoon, and five in Moulmein, though I have no doubt there were a good many more, especially at the latter place. The scarcity of specimens, however, is remarkable in a country where beautiful flowering plants are greatly prized and cultivated. The largest known tree is the one at Kogoon, the trunk of which measured 8 ft. 4½ in. in circumference* at 4 ft. 2½ in. from the ground on the 8th August, 1872. It then displayed a single spray of blossom, and seemed vigorous and healthy. I could not find the smaller one alluded to by Wallich, nor any trees of *Jonesia* or *Mesua*, which he also mentions; but a thick, tangled, wet jungle prevented me from exploring the vicinity very carefully, and they may have escaped my notice. Palmyras, Tamarinds, several species of *Ficus*, and the *Meyam* of the Burmese (*Mangifera oppositifolia*) grew in abundance close by, and formed a little tope or grove, ragged and uncared for, and fast lapsing into a wilderness. But the most beautiful *Amherstia* I have seen anywhere was in one of the compounds of the cantonment at Rangoon; and, during the cold weather, when this tree was in full bloom, nothing could exceed its rare and wondrous loveliness. It was of considerable height, and had six stems, which grew from one common root, so that, on close inspection, it looked a little like a cluster of enormous bushes. In the beginning of 1873 the circumference of this group of trunks, which were growing close to one another, was, at a short distance from the ground, 2 ft. 5½ in.

G. E. B.

CHALK AS FUEL.

SO much has been already said and written upon this subject, that it seems almost useless to prolong the discussion; still there are one or two apparently minor points of the subject to which allusion has been made, although in a cursory manner, and which do not appear to have made that impression upon those generally interested in the matter which, in a practical and economical point of view, I think, they should have done. If I were asked the question, Is chalk or limestone a source of heat? I should answer, Yes; provided I could, for the moment, banish from memory those scientific and apparently correct theories which have been from time to time advanced by eminent authorities, and which point to a different conclusion.

* In 1827, at the height of a yard, according to Wallich, its girth was 6 ft.

Speaking from practical experience only, I should, I suppose commit an error. I will, therefore, leave the point to be discussed and finally decided by those who are better qualified than myself, and refer to those seemingly minor points which should, I think, more immediately concern all connected with horticulture. Granted that chalk or limestone is not a source of heat, but simply a modifier, an absorber, a radiator of heat; are not these qualities which, for the gardener's purpose, may become invaluable? If chalk, in combination with coal, tends to modify, by absorbing for a specific time and quantity, a portion of that heat which would otherwise escape or be expended too fiercely and quickly; and if a great proportion of that heat, so absorbed by the chalk, be again radiated moderately and gradually—are not these, I would ask, the very conditions—the very qualities we require for horticultural purposes? Everyone knows how infinitely superior a moderate heat radiated from a large surface is, compared with an extreme heat from a limited surface. If this be the best principle in respect to pipes, I imagine it may be in respect to the boiler and fuel likewise. It may be argued that a portion of the heat absorbed by the chalk is retained, and cannot be liberated until it undergoes the process of slacking, and that the boiler is consequently a loser of heat to that extent; but everyone who has fairly tried this method of obtaining heat is not only willing to admit this fact, but equally willing to sacrifice this small quantity of heat, especially when the value of the lime and economy in labour are taken into account as a set-off against it. Again, it may be said by some, that this only shows the ineffective state of our present horticultural heating apparatus and the necessity for one that will thoroughly utilise every particle of heat extracted from the coal, and with the power to conserve and give it off gradually for the longest period. With all due deference to those who have had greater experience in heating than myself, I would say to this objection, mix a given quantity of culm or anthracite coal with a proper proportion of chalk, place it in a suitable furnace, and it will produce what I will call, for convenience, a gardener's or moderate heat, for a much longer period, and with infinitely less trouble than the same amount of coal, without the chalk, will produce in the best arranged furnace (whether slow-combustion or otherwise) with which it has yet been my fortune to become acquainted. I would here state that I am not now referring to what is known as "Cowan's Kiln System of Heating," of which I have seen but little—and that little has been very satisfactory, but simply stating my experience of chalk and coal combined, as an excellent fuel for horticultural purposes, after ten years' experiment and trial in various ways. To those who possess a sufficiency of pipe surface in their houses, as well as a sufficient furnace-space and boiler in their stoke-holes, I would say try this kind of fuel and be convinced; but, to those who are driving an over-burdened boiler, and who require a strong heat, regardless of the expense of fuel and staking, I would say do not, for you will be disappointed. My method is simply as follows: I have two large upright tubular boilers attached to the same apparatus, set in the usual way. The chalk having been broken into pieces about 2 in. cube, and the culm broken quite small, one of the boilers is filled quite full, mixing the fuel in equal proportions throughout. It is then lighted at the bottom, and a sufficient draught allowed to enable it to light fairly, when the dampers and fire-doors are nearly closed, just allowing sufficient air to enable it to burn steadily. In mild weather, no further attention whatever is required for two days, as I find the less it is disturbed the better. On the third day, the second boiler is started in a similar manner, and the heat in the first is allowed to cool gradually, by shutting out all draught. Should the weather, however, prove cold, a few lumps of wood are thrown on to keep up the required temperature till the second boiler has ignited properly. The lime, in consequence of its not having been burned in a properly arranged kiln, is not suitable for making mortar, but is excellent for garden or farm purposes. The advantages which I gain from the use of this fuel are—(1) a steady, moderate, long-enduring heat; (2) one-third less cost in fuel, and one-half less labour in stoking; (3) no smoke, no clinkers, few ashes, and plenty of lime without purchase. The

disadvantages are that in sudden changes of, and in very severe, weather, a barrow-load of wood per day is required to increase the temperature.

The Gardens, Wilton House.

THOMAS CHALLIS.

Single White Camellias.—These, although very beautiful, are rarely grown in nurseries. Messrs. Loddiges cultivated a white one, but, being of bad habit, it was of no value. The late Mr. Gaines, of Battersea, showed me the only one of this sort he ever raised; that was more than twenty years ago, and I regret not having secured it. I obtained one in Covent Garden some years ago; it was of excellent habit, but the flowers did not expand sufficiently, and dropped off early. A really good single white, with good anthers, would be invaluable; but where is it to be found?—C. E. J.

Anacochilus Dawsoni.—This pretty little Orchid is not sufficiently appreciated, not only for its beautiful foliage all the year round, but for the grand display of exquisite white flowers which it makes. It has bloomed with me, says Mr. Newman in the "Gardeners' Chronicle," from November until now, varying from twenty to thirty-three flowers on a spike, and when cut it will last a fortnight in a fresh state—a matter of considerable importance. A bed 4 ft. wide and 18 ft. long was made and planted last March with something over 1000 plants of it, and the sight of them is one not often seen. The foundation of the bed is made of ornamental blocks of Bath stone, which the roots cling to like a barr. Care is taken to fill up the crevices solid, with a mixture of good loam, peat, crocks broken small, with sufficient sand to keep the soil open and sweet. I am sure that with an equal number of *Goodyera discolor* or a accession of white flowers might be had at least for six months without much trouble. We intend to get all the best sorts of *Anacochilus* and plant them out: we have A. Lowii doing well, though most, if not all cultivators grow it under a bell-glass, also A. Petola, Ordianum, argentens, and intermedius; and when I am in possession of A. Veitchii, xanthophyllus, and others, the bed will be extended the whole length of the house, which is a lean-to—a low house about 32 ft. long, in which we grow *Phalanopsis*.

Raising Chrysanthemums from Seed.—Mr. Geo. Parnell a raiser of new Chrysanthemums, writing on this subject to the "Gardeners' Magazine," says, Good seed can be obtained from many of the seedsmen. Chrysanthemum seed saved from the finest flowers may be bought, and a whole year gained thereby. Those who have the space for raising a few seedlings should purchase the seed at once, and sow with as little delay as possible. The seed-pans should be well drained and filled with a rich light compost, and after the seed has been sown, place in a warm greenhouse or pit. The young plants will soon make their appearance above the soil, and provided they are watered carefully and potted off singly when strong enough, they will make sturdy plants for turning out in May. They can be put into 3-inch pots, and to promote a vigorous growth use a light and rich compost. The majority of the seedlings will bloom the first year, and in all probability some of them will be distinct and of good quality. If the number of raised seedlings be large, a few good novelties may be reasonably expected. Those who take an interest in the raising of seedling flowers, and have the time and convenience, may commence the raising of seedling Chrysanthemums with the assurance of being amply repaid for their trouble. A new variety, considered to be very beautiful, that I shall send out in the course of the season, was raised from seed supplied by Mr. W. Bull. I merely mention this to show that purchased seed is worth sowing.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Single White Camellias.—Allow me to inform "B." (see p. 172) that I procured from the Stansted Nursery, Forest Hill, last year, a one-year old single white Camellia plant, which has borne one flower this month similar to that described by him. Single white Camellias are rare.—R. E. B.

Plants Used in Perfuming Tea.—According to a Chinese authority, the principal flowers used in perfuming Tea are those of *Gardenia radicans*, *Jasminum Sambac*, *Aglaia odorata*, *Fernstrœmia japonica*, *Camellia Sasanqua*, and *Olea fragrans*, those of the last-named shrub being especially esteemed for the purpose.

Asclepias curassavica.—This, one of the prettiest and most brilliant of Asclepiads, is generally considered to be a stove plant, or one which requires wintering in heat. Having a quantity of it in the autumn, I thought I would try its hardiness. One set of plants was placed in a greenhouse, where they soon perished from damp. Another lot was placed in the dwelling-house, in an airy room where there has been no fire throughout the winter, and where at one time, for a week or more, the temperature could not have been but a degree or two above freezing; they were, of course, kept dry at the root. These have lost most of their foliage, but a few days ago, they were placed in heat, and are already giving signs of growth, thus showing that they will withstand a much lower winter temperature than that to which they are generally subjected.—J. M., *Hawkehurst, near Axminster.*

MR. VICK'S ILLUSTRATIONS.

We often admire the effective way in which woodcuts are used to illustrate articles on rural affairs in America, and in the richly illustrated catalogue of Mr. James Vick, of Rochester, we find the art carried a step farther than is usual. We mean, for example, a variety of

"The woman whose flower seeds all came up."

diminutive illustrations of the people who succeed and who fail in their gardens. Our own farmers' gardens are paradisaical compared with those one often sees in the Eastern States of America, where the Nettles are frequently allowed to look in through the window. Some are, however, better managed, and here we have a sketch of the "woman whose flower seeds all come up," and a less pleasing one of her whose seeds "come up" after another fashion. Mr.

"The woman whose seeds are scratched up."

Vick has, so far as we know, not yet figured the ascent of Adler's chickens from the Radish beds, but we shall certainly for the future search his catalogues for novelties of this kind.

Ice without an Ice-house.—Some years ago we had an ice-stack made, and this was repeated several years. The ice kept well, and thus it proved to be a simple way of providing ice in hot weather. The following was the course which we pursued:—A space was fixed upon within ten or twelve yards of the lake, on the turf, and fully exposed—no shade from trees or anything. This space was covered with faggots of brushwood, one faggot thick, placed close together, levelled, and then covered with a layer of straw. The ice was drawn off the lake, and the walls, as I may call them, were built up with large pieces of ice of all shapes, the joints being broken; in fact, they were put together like the stones in a rubble wall, the thickness being about 18 in. or 2 ft. Inside this the space was filled with pounded ice. The walls were carried up about 6 ft. high, and the pounded ice drawn in at the top in the form of a ridge. When all was packed together, the ridge was covered with a layer of straw, and some straight wheat-straw was placed round the sides. At about 2 ft. from the ice-wall some wooden hurdles were driven into the ground, and the space between filled with leaves trodden firmly in. The ridge was covered in a similar way. Over all, leaves included, was placed a layer of straw, the outside being neatly thatched. When finished, the ice-stack looked like a small hay-stack. In this way the ice kept very well all the summer. I believe a good layer of sawdust or cocoa-nut refuse next the ice, before the leaves were put on, would have been an advantage. To those (says a correspondent of "The Florist") who have no ice-house, I can recommend the stack system. Of late years we have not required to adopt this plan, as we have an excellent ice-house that gives us all that we require. I have often wondered that hotel-keepers in the country, who mostly have the opportunity, do not make some provision of this kind.

Assisting the Germination of Seeds.—According to Professor Botzger, a moderately concentrated solution of caustic soda or potash seems to promote the germination of seeds, even more than ammonia. Seeds after soaking but a few hours in diluted potash solution put forth radicles.

THE KITCHEN GARDEN.

THE CULTIVATION OF ONIONS.

The principal requirements for this crop are, thorough and deep tillage in autumn, if the land be unoccupied, or as soon after as possible, accompanied with liberal manuring. Deep stirring of the land is beneficial in many ways; it assists the drainage where the land is retentive, and, if dry and porous, it facilitates the ascent of moisture in hot weather; but in trenching land for Onions, on no account should any of the bad sub-soil be brought to the surface. Permanent improvements in this way should be done, when some other crop will follow. In addition to the manure added, during the autumn or winter culture I strongly recommend a rich surface-dressing lightly forked in, and mixed with the top soil just previous to sowing the seeds; in fact, if short of manure, I should apply it all in this way, but in preparing the ground for Onions, the second crop has to be thought of, as, after the Onions are harvested, the land is hoed up deeply, and in September it is planted with Cabbages without any other preparation. For a surface-dressing applied in the way I have indicated, any thoroughly decomposed manure will do. The decayed vegetable matter that accumulates at the rubbish heap, if well looked after, forms a most valuable fertiliser for any crop; in fact, scarcely any manure that is well decomposed and has any fertilising power at all can fail to improve the soil for the growth of Onions. If there be any reason to dread the attacks of the Onion maggot, sprinkle $\frac{1}{2}$ lb. of salt per square yard all over the surface; soot is also beneficial, but salt is more effectual than anything I have ever tried, and is besides a valuable stimulant, especially suitable for a dry, porous soil from its known affinity for moisture. The best time in most places for sowing spring Onions is as early in March as the weather will permit. The ground should be made firm either by treading or rolling, and raked level; sow in shallow drills 9 in. apart; cover the seeds thinly, and tread or roll in: sowing in loose ground and covering deeply is the chief cause of Onions growing thicknecked; but, sown in rows, the plants can be easily cleaned and the surface lightly stirred. In the growth of Onions deep stirring should be avoided, as the bulbs swell better and faster, resting on firm ground. This, of course, should not prevent a free use of the Dutch hoe to keep down weeds. If very large Onions be required, a few rows may be sown at wider intervals, and be thinned out to 5 or 6 in. in the rows, but for the bulk of the crop 9 in. between the rows and from 2 to 3 in. in the rows will be ample, as when growing they make room for themselves by swelling out on each side of the line.

Autumn-sown Onions.

In most large establishments it is necessary to keep up a supply of large-sized Onions all the year round, and, in such cases, the autumn-sown crop becomes as important as that sown in spring. I have found it best to make two sowings, the first at the end of July, and the last about the middle of August. The former sowing does for drawing green from the seed-bed, and a large portion of the latter are transplanted in February on land prepared, as for the spring-sown crop, in an open situation. Some people have an idea that transplanted Onions do not thrive so well as those not transplanted—there cannot, however, be a greater delusion. It is a very old practice, and in difficult soils, or where the maggot is destructive, Onions sown in August on a warm dry border, and transplanted in February, may generally be relied upon. The kinds usually sown in autumn are the Tripoli and Lisbon, but any other kind will succeed equally well, such as the White Spanish, Brown Globe, the Silver-skinned, and others. The Tripoli grows to a large size, but it is not a good keeper, but does well for summer use. Brown Globe and James' Long Keeping, if well grown and ripened, will keep till the autumn-sown Onions are large enough to succeed them. The different varieties of Silver-skinned are the kinds most generally esteemed for pickling, and should be sown thickly broadcast in March on hard ground without manure, covered lightly, and the beds trenched or beaten firmly with the back of the spade. In making the most of any new—or reputedly new—kind sent

out in small packets, I generally sow the seeds in a box, and start in heat early in spring, harden off, and transplant to the open ground when large enough. In this way time is gained, and the seeds are made the most of. When young green Onions are required for salads all the year round, successional sowings must be made; during winter and early spring sow either on a slight hot-bed, or in boxes in a warm house. The latter plan generally gives least trouble.

Ramsley Abbey.

E. HOBDAY.

HEELING-IN BROCCOLI.

"A. D." states (see p. 188) that Broccoli grown in private gardens is less able to bear severe frost, through the ground being deeply dug and heavily manured. Does he mean to say that market gardeners do not dig deeply and manure heavily? The majority of cultivators in private places would be very glad if they could get only half the manure which market growers use. He says heeling-in, to have effect, should be done in August. If done so early, it would seriously injure the crop by stopping the plants from attaining more than half their usual size through the check they would sustain when in the height of their growth, and it would be two months too early to have the desired effect in the way of preservation. Any one who has planted a bed of Cabbages at the latter end of October or beginning of November, cannot fail to have noticed how well these stand a severe winter compared with the earlier planted crop, evidently through the check they receive later in the season; or how is it that in an autumn when everything has been growing vigorously almost up to Christmas, much greater injury is done by severe frost ensuing than on seasons when growth has been checked beforehand by colder weather? "A. D." appears not to fully understand the process as usually carried out. Heeling-in plants of any kind ordinarily means their being taken completely up and again put in the ground. This is not the way in which gardeners treat their Broccoli crop, except when lifted with a view to clear the ground for trenching, or for some other crop that would require to be put in before the Broccoli was off in the spring, or to remove it from a damp position wherein it may happen to have been grown to a drier one, in which it will obviously stand better during severe frost, but the more general practice is to lay in the Broccoli without disturbing all the roots. If "A. D." had to grow vegetables for a large private family, he would know that the gardener who has this to do is in a very different position from the grower for market purposes. The latter will neither plant Broccoli nor any other crop for which his soil and situation are not fully adapted; the private cultivator, on the other hand, is generally obliged to grow vegetables of all kinds, for many of which the land with which he has to deal is not adapted. Many good vegetable growers plant their Broccoli without digging on ground that has borne some other crop, with a view to keep the plants in a smaller and more stunted tough state than they otherwise would be. I have frequently tried this method without laying the plants against the more liberal system of deep digging and laying, and in severe winters the laid plants invariably stood the best, although they were double the size of the others. But there is one indispensable condition in reference to the cultivation of Broccoli to enable it to withstand severe weather, and that is to grow the plants in a way that will impart to them as much solidity as possible. This can only be done by giving them plenty of room. Where the nature of the ground is such as to produce very large plants, they must be planted further apart. Instead of deep digging, as "A. D." alleges, being conducive to a tender condition, I have always found that Broccoli grown in ground that had been deeply trenched the year before stood the best, obviously through such ground being drier near the top where the roots were. As the whole Brassica family are naturally surface-rooters, deeply stirring the soil will not induce their roots to descend.

T. BAINES.

ALTHOUGH in the main I believe this to be a good old practice, yet, for reasons which, to me at least, are satisfactory, I have for several years discontinued it. In the first place, I found that the check caused by the mutilation of roots and often of foliage, certainly reduced the size of the heads—I am speaking now of late Broccoli—and this had to be submitted to every year, as there is at present no means of telling when a severe winter is coming. I found also that by giving the plants more room between the rows, and, though to a less degree, in the rows, by planting early strong plants, I procured a much hardier, stronger, and dwarfier growth, capable of standing more cold; and then, early in October, instead of heeling them in, I gave them a second earthing up with the spade, heaping the soil well up their stems—the increased space between the rows enabling this to be done—so that the crowns of

foliage rested, as it were, on a ridge of comparatively dry soil. The heavy autumn and winter rains ran down into the trenches, leaving the ridges drier, and, consequently, of a higher temperature than if all the cold rain had passed through instead of running off; whilst the snow, instead of breaking down the leaves, and ultimately melting away and leaving the hearts of the plants exposed, remained on the plants, as the leaves were supported by the ridges of soil beneath. I noticed the effect of this last winter especially, when there were many Broccoli plants destroyed in this neighbourhood, whilst I scarcely lost one. If severe weather sets in unaccompanied by snow, all that is necessary is to lay a few evergreen branches just over the hearts of the plants, or sprays of Beech with the dead leaves clinging to them, will answer as well, as it is as much for the shade imparted as for shelter. We know that a difference in climate and rainfall leads us to adopt different modes of treatment to secure given results, and I do not say the treatment recommended above would have the same results everywhere; but, of one thing I feel sure, that thick planting in freshly-dug land is the natural precursor of soft, sappy growth, that succumbs to a degree of cold that plants, differently treated, would pass through uninjured.

E. HOBDAY.

"A. D." (see p. 188) tries hard to back up his statement condemnatory of the advantages of heeling-in Broccoli for standing severe winters. That the difference in the culture of Broccoli in market and private gardens has some effect upon the hardness of the plant, there can be no doubt, and the heeling-in could not be carried out where acres of Broccoli are grown; but even then, in severe winters, such as the one of 1867, it would have paid market gardeners to have heeled-in their Broccoli, for all became useless after the thaw set in on the 23rd of January of that year. I had some breaks of Snow's Winter and Dilcock's Bride heeled-in and protected that year, and saved all; whilst other sorts, not so treated, were all lost, and none of the Brassica tribe escaped, except some late Savoy's and Curled Greens.

WILLIAM TILLERY.

Welbeck.

CAULIFLOWER GROWING AT ERFURT.

The Cauliflower around Erfurt is grown in low, swampy ground, which is thrown up in wide ridges. The plants are set on the

Cauliflower and Water-cress Culture at Erfurt.

ridges, and between these are ditches of water. Every dry day the water is bailed from these ditches upon the growing plants, and the result is Cauliflower of enormous size, compact, and almost as white as snow. The annexed engraving gives a good idea of these Cauliflower gardens and the process of watering. In the ditches Water-cress is grown, both for cutting and seed.

JAMES VICK.

Celery, Red and White.—As a white sort, I find Dwarf Incomparable to be one of the best; for, although it looks insignificant when growing beside some of the long-leaved kinds, it compares favourably with them when trimmed for use, as the heart is solid and compact, and there is little useless leaf. The Leicester Red is also an excellent kind, which, with us, has kept well. As regards the merits of growing Celery in single lines, or double and treble ones, I prefer the old plan of single rows; for, although a greater number of plants may be crowded into a given space by the double or treble systems, I question whether any other advantage is derived from its adoption, or even that the development of the Celery is so satisfactory.—J. GROOM, *Henham*.

Peas on Hot Sandy Soils.—Get the ground well manured and dug deeply, 18 in. being by no means too much. After being well dug over, and all ready for sowing, and after stretching the line where you intend sowing, in place of drawing a shallow drill with the end of a draw-hoe, take a spade, turn out a small trench—at least 8 in. deep—and, as you are digging it out, keep one foot along in the bottom, making it wide and firm; I make the bottoms of the trench, says a writer in the "Gardener," where we sow Peas, from 6 to 8 in. wide. After sowing and well regulating the Peas in the bottoms of the trench, fill it only about half full, and pat down the soil pretty firmly with the head of a rake. But when the Peas are up 6 in., fill up the sides of the Peas with stable manure and litter about half rotten; never earth up, according to the old fashion, which, when followed out on sandy soil, soon cripples Peas. Stake directly after putting the litters manure along by the drills; one can do it far better when the Peas are about 6 in. high than when left until they are higher. We always place some small twigs in the row of Peas; this assists them very greatly, as they will take hold of these ere they can fasten themselves to the stakes outside the rows. After they are staked, if the weather keeps hot, mulch all along the outside of the stakes; and when you have occasion to water the rows, the water will run towards the roots.

Asparagus in Trenches.—Asparagus delights in abundant supplies of water; and, in deep, well-drained soils, this might be made to convey nearly all the manure necessary for its successful cultivation, with the exception of mulchings and occasional sprinklings of salt. I believe there is no occasion to raise the beds into such mounds as are commonly made. A moisture-loving plant, like Asparagus, would do better (except on cold clay soil) if planted in trenches rather than on mounds, and this system of trench-planting is especially adapted for poor, light, sandy soils, as it offers such facilities for easily flooding the plants with water. In making new plantations, whether the old bed system, with its elaborate preparation (and I have no desire to find particular fault with it) be adopted, or healthy plants from one to two years old, are the best for planting, and the most suitable time is just after growth has commenced, usually in April. Where many roots are required for forcing I should certainly recommend it to be grown in single rows, not less than 2 ft. apart from each other, and at least 1 ft. apart in the rows. "The way to secure fine produce is to encourage individual growth by allowing each plant plenty of space for development; this is more profitable than thick planting, where a continual struggle for existence must be going on. It is best to raise a bed of seedlings every year sufficient to make a new plantation to take the place of that removed for forcing, or rather to come on in succession. In planting make a drill or trench wide enough to receive the roots without cramping them, cover with 2 in. of fine light soil, and water abundantly in dry weather, giving sewage or liquid manure whenever possible. When taking up the roots allow as little exposure to the air as possible to avoid giving a check.—S. J.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Williams's Matchless Red Celery.—I find this to be the best and hardiest Red Celery with which I am acquainted. It is a strong grower, solid, crisp, and excellent in flavour. It has withstood this winter's frost without damage, except a little splitting of the leaf-stems at the surface of the soil; while *Celia's Defence* and *Manchester Giant* are rotten to a pulp half-way to the roots, and the insides of the stalks, in some cases, to the roots.—W. W. EAGLEBURNET, *Worcester, Hants.*

White Emperor Potato.—This is a true white sport from the well-known red kind of that name, and is in every respect as handsome—indeed, from what I have seen of it, I am induced to believe that it will prove second to none as a handsome White Round Potato. It is not in commerce, but probably will be at the end of the year; for there are a number of choice new kinds being brought forward this year in anticipation of the great demand that is certain to arise should we be favoured with a good season.—D.

Mushrooms in Melon-beds.—We cover our old Melon-beds in houses in winter with coal ashes, and use them for *Cinerarias*, *Calceolarias*, and miscellaneous plants, and although the houses are kept quite cold, Mushrooms continue to spring up in them the whole winter through. If, too, any bed be left undisturbed in spring after the earliest Melons are started, and there are plenty of heat and moisture in the house, an abundant crop of Mushrooms may be confidently relied on, and all this without the introduction of spawn.—J. GROOM.

New American Potato Ruby.—At the recent International Potato Exhibition a small group of seedling Potatoes, exhibited by Messrs. Bliss & Son, of New York, attracted attention, as presenting the latest American improvements in that excellent. Only one variety, however, met with general approbation as being distinct in appearance and likely to prove an acquisition. That was *Prince's No. 10*, a long, smooth, handsome tuber, with a skin much the colour of Vermont Beauty, but, in shape, resembling that of the Early Rose. The eyes were shallow, and of a pretty carmine tint. I observe that Messrs. Bliss are now offering this potato under the name of Ruby, and, should it prove to be an acceptable variety amongst coloured kinds as Snowflake is amongst Whites, it will certainly become popular.—A. D.

TREES AND SHRUBS.

SPINDLE TREES.

History and Distribution.

The name *Euonymus* was applied to the common European Spindle tree long before the Linnæan nomenclature was published, and Linnaeus simply adopted it as the generic name for the species known to him in 1761. In his "Species Plantarum" he describes *E. europæus*, with two varieties, *latifolius* and *tenuifolius*, and *E. americanus*. The latter was figured in Plukenet's "Phytographia" as early as 1691 under the name of *E. virginianus*. The work just quoted is the earliest English botanical work containing tolerably faithful drawings of plants; it includes 2740 figures, many of them very good. Upwards of fifty species of *Euonymus* have been described, twenty-seven of which are found in the mountains of India. They attain their maximum in the mountains of North India, and in China and Japan, but the genus is very widely dispersed. There are four European species, three or four temperate North American, two Mexican, several in the Indian Archipelago, and one species reaches north-eastern Australia. Although several deciduous species were in cultivation in the last century, the genus dates the popularity it now enjoys from comparatively recent times. In 1804 the ordinary green-leaved state of *E. japonicus* was introduced, but it does not appear to have attracted great attention, and it is only by degrees that its value for sea-side planting and other purposes has been found out. The first variegated varieties appear to have been sent to this country about 1835, and Siebold successively introduced from Japan most of the many beautiful varieties now in cultivation. It is a remarkable fact that none of these varieties have ever been figured in any of the botanical and horticultural journals either of this country or the Continent, and yet now it would be difficult to find a garden without a *Euonymus* in it. There is a figure of the ordinary green state in the "Bot. Register," vol. xxx., t. 36, but it is a very poor one.

Culture.

The varieties of *E. japonicus* prefer a light soil and an elevated situation, or the vicinity of the sea. In low situations, and on heavy wet soils, they suffer very much from frost, even in the neighbourhood of London, especially when quite small. But there are so many uses for these plants in pots and against walls, &c., that they should find a place in almost every garden, even although not perfectly hardy in the colder parts of the kingdom. On the southern and western coasts they are perfectly at home, but they very rarely produce flowers even in the mildest parts. They are easily propagated by cuttings in the open ground, or in a cold frame or pit, according to the situation; and they are raised by thousands for the open ground, window-sill decoration, &c. They will bear close pruning better than almost any evergreen shrubs in cultivation, and most of them are rapid growers. As they are very cheap, it is of little importance that they are sometimes killed outright in the less favourable situations, because they may be replaced at a small cost. Another good quality they possess is that they transplant well. The deciduous European and North American species described below may be raised from seed, cuttings, or suckers, and they will thrive in almost any soil and situation. The natural habitat of all these species appears to be on the banks of streams and rivers. The North Indian species are only suitable for out-door culture in the warmer parts of the south-west. Many of these have scarcely been tried, and therefore little is actually known of their hardiness; and it does not follow because other plants found at the same elevation are hardy that these will prove equally so. A few remarkable deciduous species from north-eastern Asia are included in the selection below.

European Species.

(All having deciduous leaves, or only half-evergreen.)

1. *E. europæus*.—The common Spindle tree is one of the most ornamental of our native shrubs in autumn, when the pale scarlet fruit is open, revealing the orange-coloured aril of the seeds; but as there are several handsomer species in cultivation, notably *latifolius* s

and atropurpureus, it is scarcely worthy of a place in the garden. In mild winters it is like the indigenous Privet, almost evergreen. There are several varieties, including one with variegated leaves, and another with a white capsule; but the most desirable is the variety nanus, from the Caucasus, a dwarf, trailing shrub, with very small narrow leaves, 1 to 2 in. long; it is suitable for running over rockwork. This species has a wide range of distribution in Europe, North Africa, and Western Asia.

2. *E. latifolius*.—This Linnaeus regarded as a variety of the last, but it is now generally admitted to be a distinct species, and it is far superior as an ornamental shrub. It has oblong-lanceolate, acutely acuminate, finely toothed leaves, 3 to 5 or occasionally 6 in. long, and the flower-cymes are borne on much longer (usually 2½ to 4 in.) peduncles. The capsule, too, is more highly coloured. According to Loudon this species is easily distinguished by its reddish-green bark, and long-pointed, dark brown leaf-buds. A native of some parts of the Rhine Valley, Herzegovina, Carniola, &c., in Europe, and possibly also of North-eastern Asia.

3. *E. verrucosus*.—A very distinct species, easily known by its slender red verrucose or warty shoots. It has nearly sessile ovate-lanceolate, acuminate, crenate-serrate leaves, about 2 in. long, and the usually three-flowered cymes exceed the leaves in length. The flowers are reddish in colour, and the fruit small and much less conspicuous than in either of the two last. This species is a native of the centre and south of Eastern Europe, and was introduced into this country in 1763.

4. *E. velutinus*.—This differs from all the other species described here, in being densely clothed with a felt of soft woolly hairs. It is a deciduous shrub, with lanceolate, minutely-toothed leaves, from 2 to 3½ in. long, and rather large flowers, usually borne in pairs, on a peduncle much shorter than the leaves. The fruit is slightly downy. A native of the Eastern Caucasus, introduced in 1838.

American Species.

(Both with deciduous foliage.)

5. *E. atropurpureus* (Burning Bush).—A tall, upright-growing shrub, from 6 to 14 ft. high; leaves stalked, oval-oblong, pointed; flowers, dark purple, with the parts usually in fours, capsule scarlet and smooth, deeply lobed. A native of the Eastern and Central States, from New York southward; it is common in Kentucky, where the fruit is said to ripen about the middle of October, and remain on the bush nearly all the winter. This fruits in such profusion, and the fruit is so highly coloured that it has received the name of Burning Bush in its native country. In England it does not appear to fruit so freely as *E. latifolius*, which is an exceedingly striking object in autumn when laden with fruit. Introduced in 1756.

6. *E. americanus* (Strawberry Bush) Loddiges' Bot. Cab., t. 1322.—This is an erect or trailing shrub, 2 to 5 ft. high, with thicker almost sessile leaves, more variable in shape, varying from ovate to oblong, lanceolate, acute or acuminate; flowers greenish-purple, with the parts usually in fives; carpels rough and warty, or almost prickly, crimson when ripe; aril of the seed scarlet. *E. obovatus* is a trailing variety of this, with flowering stems 1 to 2 ft. high, and thin, obovate or oblong leaves. It grows in low or wet places. The ordinary form grows on wooded river-banks, from New York and Illinois southwards. In Kentucky it is said to be a very striking object overhanging the perpendicular rocks of some of the water-courses. It was introduced into this country in 1683, but it is rarely seen now.

Chinese and Japanese Species.

1. Species with evergreen leaves.

7. *E. hederaceus*.—A prostrate or trailing (or sometimes erect) shrub, with broad, thick leaves and angular branches, which readily throw out roots when trailing over rocks. Leaves stalked, usually ovate, with a tapering point 2 to 3 in. long and narrowed at the base, but varying to narrow, oval-elliptical, or nearly lanceolate, or occasionally very broad and obtuse, of Laurel-like consistency, with few prominent veins. Flowers greenish white, few together in very short cymes. Capsule nearly globular, with slight furrows answering to the partitions. Seed enveloped in a scarlet aril. Colonel Champion first discovered this singular species spreading over the rocks in the Happy Valley, Hong Kong, and Wilford afterwards found an erect tree of the same species.

8. *E. nitidus*.—An evergreen shrub with thick, leathery, ovate or obovate, entire, glossy leaves, about 2 in. long. Flowers greenish, in axillary cymes, shorter than the leaves. Capsule naked, red. This species was sent home by Fortune, and was briefly described by Dr. Lindley in the sixth volume of the "Transactions of the Royal Horticultural Society," under the name of *E. sinensis*. He speaks of it there as likely to prove hardy, but it seems to have disappeared

from cultivation. It is a native of the island of Hong Kong and the adjacent mainland, and is, therefore, certainly not hardy in this country. There are specimens of it in Griffith's herbarium at Kew, from Bengal, where it is probably an introduced plant.

9. *E. longiflorus*.—An evergreen species remarkable for its long, narrow leaves, 4 to 6 in. long, and ½ to 1½ in. broad. The light green flowers are borne in dense, shortly-stalked cymes. Capsules reddish-coloured, flat at the top, with spreading rounded lobes. This is also a native of Hong Kong, and though not hardy in Britain, except such exceptionally rainy parts as the Scilly Isles, it would be in many countries where THE GARDEN finds readers.

10. *E. laxiflorus*.—A perfectly glabrous, erect evergreen shrub, resembling *E. japonicus*. Leaves stalked, ovate-elliptical, obtusely acuminate, 1½ to 3 in. long, quite entire, or with a few crenatures, tapering at the base, smooth and shining. Flowers purplish, rather large for the genus, arranged in loose cymes nearly as long as the leaves. Capsule flat at the top, with spreading lobes. A very ornamental shrub from Hong Kong.

11. *E. japonicus*.—This species is now so well known as to scarcely need description. Introduced at the beginning of the present century, it has been propagated by thousands or even by millions, and now, in the south, at least, it has become one of the commonest shrubs in small town gardens, and in many towns on the sea-coast, where it finds the most favourable conditions, it is simply invaluable, and greatly relieves the former monotony of Tamariak. Besides the normal variety with glossy dark green leaves, several others have been introduced from Japan, there are the varieties *foliis aureo* et *argenteo marginatis*, in which the leaves are elegantly bordered with white or yellow; *E. j. foliis variegatis* has the leaves variously marked and variegated with white or yellow; *medio pica* has leaves with a yellow centre, bordered with green; and there is a set of broad-leaved varieties which bear the additional appellation of *latifolia*. A variety with curled leaves is called *microphylla*. Coming to the radicans set of varieties, we should mention that Professor Koch (Dendrologie) contends that the true radicans is distinct as a species from *E. japonicus*. We cannot concur in this view for several reasons. In the first place, there are several other species, *E. heteracrus* and *echinatus*, for example, which exhibit the same peculiarity of scandent and erect varieties; and, secondly, botanists who have had opportunities of investigating the question in their native country assure that they are simply states of the same species. In the Herbarium at Kew there are wild or at all events Japanese specimens of the varieties radicans, spontanea, with obovate-lanceolate leaves, and the variety *foliis aureo variegatis*. Whether belonging to a natural species or otherwise, the varieties of radicans are charming shrubs for covering small spaces on walls, rock-work, &c., attaching themselves by adventitious roots, like the Ivy. The best is, perhaps, the silver variegated variety. But the varieties *foliis roseo marginatis*, *foliis aureo marginatis*, *tricolor*, &c., are all deserving of a place in the garden. The Japanese and Chinese, it would appear, are as partial to them as we are. The ordinary *E. japonicus* is commonly employed for forming hedges in Japan, and, according to a note accompanying one of Oldham's specimens, it grows abundantly near the sea. In this country it rarely flowers, and we never heard of its bearing its nearly globular capsules. Indeed, we only heard of its flowering in Brighton for the first time last year.

2. Species with deciduous leaves.

12. *E. subtriflorus*.—A deciduous or half-deciduous shrub, with small ovate-lanceolate acuminate leaves, 1 to 2 in. long, very finely saw-toothed, with very short stalks, smooth. Flowers usually, but not always, in threes, on a peduncle about half as long as the leaves. Capsule deeply lobed, in fact, the cells almost become separate carpels, and two or three of them are sometimes abortive. A common Japanese shrub, not yet in cultivation in this country. Dr. Regel considers this a variety of *E. Thunbergianus*.

13. *E. Sieboldianus*.—A deciduous shrub, with very variable leaves as to size and shape, ranging from 2 to 6 in. in length, and lanceolate, oblong, or obovate, rounded at the top or with a tapering point. Capsule with four acute angles, slightly warty. A native of Japan and Sachalin Island, possessing no particularly ornamental features.

14. *E. Maackii*.—Near *E. europæus*, but differing in its much harder somewhat leathery leaves, smooth, not rugulose, below, the upper ones elliptical lanceolate, with a long tapering point, margin saw-toothed, and in its violet-black (not yellow) anthers. Bark of the old wood of an obscure purple-black. A native of the Amur country, in North-east Asia, discovered by Maack. Judging from dried specimens, we should think this is a variety of *E. europæus*, and, if

specifically distinct, it is not very different in general appearance. Regel, in his "Flora Ussuriensis," regards it as a variety of *E. europaeus*.

15. *E. macropterus*.—A very distinct species, approaching *E. latifolius* in its leaves, which are more or less broadly obovate, with a tapering point. The most remarkable character of this species is its large four-winged capsule, differing in this respect from all the others of the genus from this region. The wings of the capsule are rose-pink, and about $\frac{1}{2}$ -in. long. It is a shrub from 8 to 10 ft. high, with branches about an inch in diameter; bark, greyish-brown, with longitudinal plates; lenticels small, whitish. This hardy and doubtless very ornamental species grows in rocky ground on the banks of the Amur river, on the island of Sachalin, and on the coast of Manchuria.

16. *E. thunbergianus* (*Melanocarya alata*, Turczaninow in the "Moscow Bulletin," xxxi., p. 1; *Colastrum alatum* Thunberg).—A deciduous species, remarkable for the broad, corky wings of the young branches. It has ovate-lanceolate, acuminate, very finely serrated, glabrous leaves, from 1½ to 2 in. long, and borne on very short stalks; flowers small, capsule often reduced by abortion to a single, oblong, cylindrical carpel. This very distinct species is widely spread in Japan, the Korea, Amur, &c. It is described as a charming shrub by Koch, who states that it is in cultivation in the Berlin Botanic Garden.

17. *E. micranthus*.—There are some specimens in Kew Herbarium from North China under this name, but as the flowers are larger than those of at least half of the species, the name is not an appropriate one. In its foliage this resembles a Poplar, and differs from all other species in the leaves being borne on slender stalks, nearly an inch long. The leaves are perfectly glabrous, ovate or elliptical, tapering into a very long point, and finely serrated, apparently half-evergreen, with long, slender, smooth, yellow-barked branches. *E. beigeanus*, of Maximowicz, found in the neighbourhood of Peking, is perhaps the name that should be adopted for this species. Probably the true *E. micranthus* of Don is a different species, and in Hooker's "Flora of India," it is doubtfully referred to *E. fimbriatus*.

North Indian Species.

(Chiefly evergreens).

18. *E. grandiflorus*.—A small evergreen tree, or sometimes bushy. Leaves 3 to 4 in. long, ovate-lanceolate to obovate or obovate-oblong, minutely serrated upwards, shining and dark green above, pale beneath, or almost black in dried specimens. Flowers with the parts in fours, usually three together, on slender peduncles, nearly equaling the leaves, from $\frac{1}{2}$ to nearly 1 in. in diameter. Petals white, nearly orbicular. Fruit $\frac{1}{2}$ in. in diameter, globose, with four rounded angles, yellow seeds, black, shining, partly enveloped in a scarlet aril. This is one of the most ornamental species of the genus, whether in flower or in fruit, the flowers being very large for the genus, and comparatively showy. It is a native of the temperate regions of the Western Himalaya Mountains. In Khasia it is found at an elevation of between 4000 and 6000 ft. Introduced in 1824. There is no figure of it in any easily accessible books, but there is a fine plate of it in Wallich's "Planta Asiaticae Rariores," t. 254.

19. *E. tingens*.—A small evergreen tree, 16 to 20 ft. high, with a short erect trunk, $\frac{1}{2}$ to 3 ft. in girth, with a few branches, forming a small rounded crown; leaves 1 to 3 in. long by 8 to 12 lines broad, thick and coriaceous, glabrous and shining, rugose above, ovate or ovate-lanceolate, obtusely serrate or crenate, acute and sometimes shortly acuminate, on short petioles, with brown, subulate, fringed stipules; flowers about $\frac{1}{2}$ in. in diameter, few together in dichotomous, axillary cymes, subtended by fringed bractlets; petals orbicular, with a short claw, white or yellowish, beautifully marked with dark purple veins; fruit, three, four, or five-cornered, not winged; seeds oblong, with a cup-shaped aril. This is also a very ornamental species in its flowers, and Dr. Brandis thinks it may possibly be a variety of *E. grandiflorus*; but, from a horticultural point of view, it is quite distinct in its elegantly-veined purple and white or yellow flowers; it has a dark ash-grey or yellowish-brown bark covered with numerous yellow tubercles. It is widely distributed in the mountains of Northern India, at an elevation of 6500 to 10,000 ft., and therefore nearly or quite hardy in the milder parts of the United Kingdom. We do not know the date of its introduction into this country, but it has been, and for aught we know to the contrary, may still be, in cultivation. In some of the botanical dictionaries this species is erroneously reported from Japan.

20. *E. bullatus* (Loddiges' Bot. Cab., t. 1749).—An evergreen shrub or small tree, remarkable for its large, thick, bullate, ovate leaves, which in some specimens are 10 in. long by 4 in. broad, entire,

or minutely toothed towards the apex, nerves very prominent below; flowers white, rather small, very numerous in large much-branched cymes; fruit four-lobed, roundish, colour not known to us. A native of the Khasia Mountains, in the sub-tropical regions. It was formerly cultivated by Loddiges, but we have not seen it in a living state.

21. *E. fimbriatus* (*E. lacerus*, in Brandis's Forest Flora).—An elegant deciduous tree, attaining a height of 25 ft. Leaves 2 to 4 in. long, glabrous, membranous, elliptical, or broadly ovate, shortly acuminate, finely and often doubly serrated. Flowers small, white, very numerous, in umbellate cymes, borne on long, slender peduncles. Capsule with from two to five vertical, long, tapering wings, the valves, when ripe, spreading out flat when open. Seeds ovoid, enclosed in a bright, red aril. This handsome species is a native of the temperate regions of the mountains of northern India, occurring at an elevation of between 10,000 and 12,000 ft. in Sikkim, and between 8000 and 10,000 in the north-west Himalaya. Dr. Brandis says that the dark green leaves change red in autumn before falling, and the bright red seeds are strung and used as ornaments. Professor Lawson thinks the woodcut given in Paxton's "Flower Garden" ii., t. 316, can hardly belong to this species, the leaves resembling more those of *E. pendulus* or *E. frigidus*.

22. *E. frigidus*.—A dwarf shrub, with thick, succulent shoots and very variable leaves, linear, linear-lanceolate, to broadly-lanceolate, acuminate, serrate, 3 to 5 in. long by $\frac{1}{2}$ to $\frac{1}{3}$ in. broad. Flowers very small and white. Fruit with four long tapering wings. A native of Sikkim, Himalaya, at 8000 to 12,000 ft. elevation, and most likely quite hardy in this country. There is a variety with leaves 1 ft. long by $\frac{1}{2}$ of an inch wide.

23. *E. echinatus* (Bot. Mag., t. 2767; *E. scandens* of Graham).—An evergreen shrub, often climbing and trailing like Ivy to a considerable distance over trees and damp-shaded rocks, attaching itself by dense tufts of adventitious roots; or occasionally a small, handsome tree 15 to 20 ft. high, with a short, straight trunk 12 to 16 in. in girth. Branchlets tetragonal, with four thick lines decurrent from either side of the petioles. Leaves 2 to 3 in. long, coriaceous, oblong-lanceolate, crenate, or obtusely serrate, borne on short stalks. Cymes axillary, shorter than the leaves, with three to ten pea-green, scentless flowers. Capsule globose, thickly beset with long prickles. Seeds entirely enveloped in a thin scarlet aril. This species is very distinct from all others in its spiny fruit. It is common in many parts of the Himalayan range between 7000 and 12,000 ft. above the level of the sea. It was introduced in 1824, and there is a figure of it in the "Botanical Magazine" quoted above. According to Dr. Brandis, the fruit often remains hanging on the branches for several months. The same, or a very closely allied species, is found in China and the Loo-Choo Islands.

24. *E. theaeifolius*.—A small erect shrub, with coriaceous ovate or oblong-lanceolate leaves, resembling those of the Tea shrub. Flowers small, reddish, capsule nearly spherical, the size of a large Pea, obscurely angled and usually only one-seeded. A native of the Himalayan range, at an elevation of between 4000 and 8000 ft. This does not appear to have been introduced into this country yet.

25. *E. pendulus*.—An elegant tree, sometimes attaining a height of 40 ft., with a straight trunk $\frac{1}{2}$ ft. in girth; branchlets slender, pendulous; leaves 2 to 4 in. long, oblong-lanceolate, coriaceous, and shining when young, dull grey as they become older; flowers white, with fringed oblong petals, about 4 lines in diameter, arranged in three to twenty flowered cymes; capsule three or four-lobed, the angles and back more or less winged; seeds inclosed in a thin aril. This handsome species is widely dispersed in the Himalayan mountains, though nowhere common. It ranges between 2500 and 8500 ft. above the sea level, and varies considerably in stature at different elevations. It has been confounded with *E. japonicus*, but it is quite distinct in its fruit and other characters from that species.

26. *E. Hamiltonianus*.—A large shrub, or in favourable situations a small tree, with round, glabrous, green branchlets; leaves 2 to 5 in. long, glabrous, membranous, oblong-lanceolate, finely serrate, acuminate, borne on petioles 4 to 6 lines long; flowers greenish white, small; petals oblong, obtuse, not fringed; capsule yellow, deeply four-lobed, not winged; seeds entirely enveloped in a scarlet aril. This ornamental species is hardy in the milder parts of the United Kingdom, and forms a fine greenhouse shrub. It is found in the Himalayan range, from the Indus to Bhutan, at an elevation of 3800 to 8500 ft. Dr. Brandis informs us that it usually grows in mixed forests where there is some shade. The wood is beautifully white, compact, and close, and is used for making spoons. The young shoots and leaves are lopped for fodder. Introduced in 1825. There are some specimens in Kew Herbarium from Japan and the Korea under this name, but they probably belong to another species.

W. B. HEMSLEY.

ROYAL HORTICULTURAL SOCIETY.

At the annual meeting of the 10th inst., when the vote of want of confidence in the Council was rejected, a Committee of six was chosen to confer with the Council. Being one of the six I had a right to advise, and sent to the President what I believe to be a working scheme which might still save the Society, whose days are numbered, unless a new source of support and income is found, and that without delay.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

The following is the scheme to which allusion has just been made:—"The Council of the Royal Horticultural Society apply to the horticulturists of the country under circumstances of great difficulty. The Society is doing important and useful work which benefits all who value their gardens or who care for fruit, vegetables, or flowers. Its scientific Committee is now the recognised authority on new plant plagues of all descriptions, and does much other valuable work. Its Fruit and Floral Committees examine new fruits, vegetables, and flowers, work which can only be done by a great central society; their judgments, immediately published by means of the gardening press, are now received with respect through the country. In the Society's garden at Chiswick flowers, fruit, and vegetables are grown side by side, are tested and judged by the highest authorities, and troublesome synonyms got rid of. The Society's income does not meet its necessary expenditure. Her Majesty's Commissioners will extend the lease of the South Kensington Garden if the income of the Society within three years is raised to £10,000 a year. Great efforts are being made to induce residents in the neighbourhood of the South Kensington Garden to become Fellows in order to preserve their recreation ground, but it is doubted that sufficient and timely aid will come in from this source. Many of the best horticulturists of the country have held aloof from the Society mainly on the ground that too much of its income goes to keep up the South Kensington Garden rather than to advance horticultural science, and in the belief that while resident Fellows have ample consideration for their subscriptions, Fellows at a distance have not so. It is now proposed to have two classes of Fellows, those who pay the present subscription of £4 4s. and £2 2s., who will have all the privileges of the Society, and those who care only for the horticultural work of the Society; these last will be made Fellows for an annual subscription of one guinea, and will be admitted to all shows great and small, and to the Chiswick Garden, but will not have the use of the South Kensington garden as a recreation ground, or be admitted on Saturday when the band plays, or to any non-horticultural entertainment. Country horticulturists are reminded that it is much easier to improve an existing society than to raise up a new one; that the Society has the name 'Royal,' and the garden at Chiswick, with all its old associations; and that a guinea subscription to a working, useful society is a very moderate one. The Council now call on all good horticulturists throughout the country, and especially on lady and clergymen horticulturists, to come forward and help them by sending in their names as would-be guinea Fellows, by making lists and forming local committees, and by canvassing such of their friends as would be suitable Fellows, and to do this without loss of time. Any guinea subscriber will be liable only for the amount of his subscription."

H. W.

Darwin's "Insectivorous Plants."—The following is the closing paragraph of Principal Dawson's review of this work in the January number of "The International Review":—"When he closes his long and elaborate investigation of *Drosera* with the words, 'We see how little has been made out in comparison with what remains unexplained and unknown,' we have an admonition to humility and patient inquiry which may well serve us as a closing thought. These words occur at the end of a tersely written record of experiments and observations extending over 270 pages. The whole of these experiments and observations relate to the structures and functions of a little leaf $\frac{1}{2}$ in. in diameter, and they are the work of one of the most accomplished naturalists of our time, extending over a period of fifteen years, and assisted by many specialists in the chemical and physiological questions involved. Yet the impression remains in the mind that, after all, little has been made out compared with what remains unexplained and unknown, even in relation to this almost inappreciable fragment of the great system of Nature."

Explaining it.—In speaking in rather complimentary terms of a young artist's work, Mr. Ruskin made a remark to the effect that he would have to go through the Valley of Humiliation before reaching the Mountains of Beatitude. Hereupon the young artist wrote to Mr. Ruskin saying that he greatly valued the advice of so eminent a critic, and that he would be highly delighted to know what this phrase actually meant. Mr. Ruskin's reply was characteristically whimsical. He told his correspondent to take a tumbler,

place it bottom upwards, put half a dozen Cherries round the tumbler, and send him a water-colour sketch of this subject; then he would tell him his meaning. The artist, manfully going into the Valley of Humiliation, did as he was bid, and sent the sketch. Mr. Ruskin returned the sketch, quietly asking why the shadow of Cherry number six had been made broader than the shadow of Cherry number five, whereas it ought to have been narrower? The ingenious painter humbly replied that, although he might have made a mistake, his object had been to elicit from the great master of artistic criticism some definite explanation of the enigmatical phrase above quoted. The answer to this was not enigmatical. "If you can't draw a Cherry, why do you presume to paint women's heads?"

CENTRAL HORTICULTURAL SOCIETY OF FRANCE.

At the fortnightly meeting of this Society, held on the 9th of December last, M. Hédarid, foreign fruit merchant, sent a number of fruits of *Sechium edule*, which somewhat resemble in shape the Castard Vegetable Marrow. They had been received by him from Algiers, where they are highly esteemed as a vegetable, tasting, when cooked, something like Cauliflowers, and called by the French colony there *Chayottes*. The native country of this vegetable is at present unknown, De Candolle, in his "Prodromus," merely stating that it is to be found in great quantities in the Antilles. The Committee of the Society, who had tasted it, did not report so favourably as to its merits as might have been expected from the high estimation in which it is held in Algiers; but inexperience as to the proper method of cooking and preparing it may have had a good deal to do with this, and on further acquaintance this vegetable may, I should think, improve. At the same meeting a letter was read from M. L'Herron, a nurseryman at Brest (Finistère) claiming the merit of having invented some special method of cultivating *Camellias* in the open air without any kind of protection, which method is as yet known to no one but himself. Another letter was read from M. Dubuc, describing a new method of destroying aphides or green fly on Peach trees by copiously syringing the trees in time of severe frost, the coating of ice formed on all the twigs and branches effectively destroying the fly and its eggs, without in any way injuring the trees themselves. M. Dubuc also thinks the same treatment might advantageously be applied to Roses. At the meeting on December 23rd the Duc Decazes was elected President for 1876-7-8-9, obtaining 95 votes out of 183 recorded, the retiring President M. Brougniet, receiving 83. The popular and eminently efficient Secretary-General, M. Alphonse Lavallée, was re-elected by 162 votes out of 180 recorded for the four years next following, and M. B. Verlot as *Secrétaire Général adjoint*, and Messieurs J. Leclair, H. R. Dumont, E. Delamane, and J. Durviver, Joint Secretaries.

W. E. G.

The Weather and the Moon.—Mr. Preston Powers' statement in reference to the effect of the moon on vegetation (see p. 168) has induced me to send you the following from the "Visitors' Book" at Bala:

The weather depends on the moon as a rule,

And I've found that the saying is true.

For at Bala it rains when the moon's at the full,

And it rains when the moon's at the new;

When the moon's at the quarter, then down comes the rain,

At the half it's no better, I ween;

When the moon's at three-quarters 't's at it again,"

And it rains besides mostly between.—A.

NOTES AND QUESTIONS—VARIOUS.
